$$\frac{d^ny}{dx^n} = (-1)^n\frac{\Gamma\left(\frac{\alpha}{\beta} + n\right)}{\Gamma\left(\frac{\alpha}{\beta}\right)}\cdot\frac{(y + b)}{(x + a)^n}$$

and that

$$\frac{d^m x}{dy^m} = (-1)^m \frac{\Gamma\left(\frac{\beta}{\alpha} + m\right)}{\Gamma\left(\frac{\beta}{\alpha}\right)} \cdot \frac{(x+a)}{(y+b)^m}.$$

Hence

$$\frac{d^n y}{dx^n} \cdot \frac{d^m x}{dy^m} = (-1)^{n+m} \frac{\Gamma\left(\frac{\alpha}{\beta} + n\right)\Gamma\left(\frac{\beta}{\alpha} + m\right)}{\Gamma\left(\frac{\alpha}{\beta}\right)\Gamma\left(\frac{\beta}{\alpha}\right)} \cdot \frac{1}{(x+a)^{n-1}(y+b)^{m-1}}.$$

Choosing $\alpha = n-1$, $\beta = m-1$ now gives the result—readily seen to hold for $m = n$.

A NOTE ON PARTITION-INDUCING RELATIONS

CHARLES GREEN, University of Maine

Let R be a relation in the set S. Let us say that *R induces a partition of S* if there exists a partition of S such that for all x, $y \in S$ with $x \neq y$, x and y belong to the same set in the partition iff $(x, y) \in R$. Harary [1, corollary, p. 215] has proved that R induces a partition of S iff R is symmetric and distinctly transitive. The proof depends on concepts from graph theory. In this note we point out another proof which has the advantage of characterizing the sets in the induced partition.

LEMMA. *Let R be a relation in S and let I be the identity relation on S. Then R is symmetric and distinctly transitive iff $R \cup I$ is an equivalence.*

Proof. It is clear that neither adding nor deleting pairs of the form (x, x) affects symmetry and distinct transitivity. Thus $R \cup I$ is reflexive, symmetric, and distinctly transitive iff R is symmetric and distinctly transitive. But a reflexive, symmetric, and distinctly transitive relation is an equivalence [1, p. 215].

THEOREM. *R induces a partition of S iff R is symmetric and distinctly transitive. If R does induce a partition, its elements are the equivalence classes of S with respect to $R \cup I$.*

Proof. The first statement follows from the lemma and the one-to-one correspondence between equivalences and partitions; the second from the fact that for $x \neq y$, $(x, y) \in R \cup I$ iff $(x, y) \in R$.

A NOTE ON HOMOTOPY THEORY

J. M. ADAMS, New Mexico State University

If A and B are topological spaces, let $C(A, B)$ denote the set of all continuous functions from A to B with the compact-open topology. If X and Y are topological spaces and I is the closed unit interval $[0, 1]$, then $C(X, C(I, Y))$ is homeomorphic to $C(I\times X, Y)$ (cf. [2]). Using this fact, it is easy to prove that the usual definition of homotopy between two continuous functions is equivalent to the following definition.

DEFINITION. *Let f and g belong to $C(X, Y)$; f is homotopic to g iff there exists an element h in $C(X, C(I, Y))$ such that $h(x)(0)=f(x)$ and $h(x)(1)=g(x)$, for each x in X.*

A development of homotopy theory including this equivalent definition along with the usual definition, has the following important advantages:

1. Geometrical appeal, since $h(x)(t)$, for $0\leqq t\leqq 1$ and fixed x in X, is actually the deformation of the point $f(x)$ into the point $g(x)$,
2. Obvious relationship with the relatively recent development of homotopy theory in R-modules [1] or abelian categories [3], where the usual definition is analogous to i-homotopy (based on injectives) and the equivalent definition is analogous to p-homotopy (based on projectives), and
3. Simplification of proofs of some theorems (see the theorem below).

THEOREM. *If Y is a contractible topological space, then every continuous function f of X into Y is homotopic to a constant function.*

Proof. By hypothesis, the identity function on Y is homotopic to a constant function by means of $h\in C(Y, C(I, Y))$. Now f is homotopic to a constant function by the composition $h\circ f: X\to C(I, Y)$.

ON BEING MEAN TO THE MEAN VALUE THEOREM

LEON W. COHEN, University of Maryland

With characteristic vigor, L. Bers announced in a recent conversation: "Who needs the mean value theorem! All we want as a start in elementary calculus is the proposition that if $f'(x)=0$ for all x in $[a, b]$, then f is constant." A subsequent conversation indicated that the proof given here is different from that of Professor Bers.

REMARK. If $P=(x, y)$, $Q=(u, v)$, $R=(s, t)$, $x\leqq s\leqq u$, and m, m', m'' are the

slopes of PQ, PR, RQ respectively, and $x<u$, then $m \leqq \max\{m', m''\}$. (Proof later.)

Now suppose $f'(x)=0$ on $[a, b]$, $a \leqq a_1 < b_1 \leqq b$, and $f(a_1) < f(b_1)$. Let $c_1 = (a_1+b_1)/2$, $P_1=(a_1, f(a_1))$, $Q_1=(b_1, f(b_1))$, and $R_1=(c_1, f(c_1))$. By the Remark, one of $[a_1, c_1]$, $[c_1, b_1]$, which we call $[a_2, b_2]$, is such that

$$m_2 = \frac{f(b_2) - f(a_2)}{b_2 - a_2} \geqq m_1 = \frac{f(b_1) - f(a_1)}{b_1 - a_1} > 0.$$

By induction, we find for each k an interval $[a_k, b_k]$ such that

(1) $$[a_{k+1}, b_{k+1}] \subset [a_k, b_k], \qquad b_{k+1} - a_{k+1} = (b_k - a_k)/2 = (b_1 - a_1)/2^k$$

and $m_k = (f(b_k) - f(a_k))/(b_k - a_k)$ such that

(2) $$m_{k+1} \geqq m_k \geqq m_1 > 0.$$

Since by (1), $\lim_k (b_k - a_k) = 0$, $\bigcap_k [a_k, b_k]$ contains a single point x_0. Since $a_k \leqq x_0 \leqq b_k$, the Remark assures us that we can define x_k as a_k or b_k so that

(3) $$\frac{f(x_k) - f(x_0)}{x_k - x_0} \geqq m_k.$$

Now $\lim_k x_k = x_0$ since $|x_{k+1} - x_0| \leqq b_{k+1} - a_{k+1} = (b_1 - a_1)/2^k$. By the hypothesis, (2) and (3),

$$0 = f'(x_0) = \lim_k \frac{f(x_k) - f(x_0)}{x_k - x_0} \geqq m_1 > 0.$$

This is impossible. In case $f(a_1) > f(b_1)$, we put $g(x) = -f(x)$.

Proof of Remark. If $s=x$, $m=m''$ and if $s=u$, $m=m'$. If $x<s<u$, $s = x + \alpha(u-x)$, where $0<\alpha<1$. If $t \geqq y + \alpha(v-y)$, i.e. R is on or above PQ, then

$$m' - m = \frac{t - y}{\alpha(u - x)} - \frac{v - y}{u - x} = \frac{t - y - \alpha(v - y)}{\alpha(u - x)} \geqq 0.$$

If $t \leqq y + \alpha(v-y)$, i.e. R is on or below PQ, then

$$m'' - m = \frac{v - t}{(1 - \alpha)(u - x)} - \frac{v - y}{u - x} = \frac{y + \alpha(v - y) - t}{(1 - \alpha)(u - x)} \geqq 0.$$

In either case $m \leqq \max\{m', m''\}$.

In connection with the construction used above, the reader may be interested in recent work on ordinary differential equations in a vector space by A. K. Aziz and J. B. Diaz. Their paper [1] contains an extensive bibliography.

ON AVOIDING THE MEAN VALUE THEOREM

LIPMAN BERS, Columbia University

The arrangement (hardly a new one*), which I had in mind when talking to Leon Cohen [1], is as follows.

THEOREM. *If* $f'(x)>0$ *for* $a<x<b$, *then* f *is increasing.*

This is intuitively obvious and easy to prove. Indeed, assume there is a p, $a<p<b$, such that the set S of all x, $a<x<p$, with $f(x)\geqq f(p)$ is not empty. Set $q=\sup S$; since $f'(p)>0$, we have $a<q<p$. If $f(q)\geqq f(p)$, then since $f'(q)>0$, there are points of S to the right of q. If $f(q)<f(p)$, then q is not in S and, by continuity, there are no points of S near and to the left of q. Contradiction.

COROLLARY 1. *If* $f'(x)\geqq 0$ *for* $a<x<b$, *then* f *is nondecreasing.* (Apply the theorem to $f(x)+\epsilon x$, $\epsilon>0$.)

This implies that a function with an identically vanishing derivative is constant.

COROLLARY 2. *If* $f'(x)\leqq K$ *for* $a\leqq x\leqq b$, *then* $f(b)\leqq f(a)+K(b-a)$. (Apply Corollary 1 to $K(x-a)-f(x)$.)

Using the intermediate value theorem and either Corollary 2 or the fundamental theorem of calculus, one obtains at once the mean value theorem for continuously differentiable functions. That's all one needs in calculus.

The "full" mean value theorem, for differentiable but not continuously differentiable functions, is a curiosity. It may be discussed together with another curiosity, Darboux' theorem that every derivative obeys the intermediate value theorem.

* I would be grateful to any reader who may know of a reference.

NONNORMALITY OF LINEAR COMBINATIONS OF NORMALLY DISTRIBUTED RANDOM VARIABLES

G. E. ALBERT AND R. L. TITTLE, University of Tennessee

Rosenberg [1] has given an example of a bivariate distribution function which is not a normal distribution but for which the marginal distributions of the individual variables x_i, $i=1, 2$, are normal. Also the distribution of the sum x_1+x_2 is not normal. In this note we present such an example for which the demonstration of the stated properties is much simpler than in Rosenberg's example.

Let a bivariate probability density function $f(x_1, x_2)$ be defined over the plane by

$$(1)\qquad f(x_1, x_2) = \begin{cases} \frac{1}{\pi}\exp[-\frac{1}{2}(x_1^2 + x_2^2)] & \text{if } x_1 \geqq 0,\ x_2 \geqq 0, \text{ or if} \\ & x_1 \leqq 0,\ x_2 \leqq 0, \\ 0 \quad \text{if } x_1 > 0,\ x_2 \leqq 0 \quad \text{or if} \quad x_1 \leqq 0,\ x_2 > 0. \end{cases}$$

Note that $f(x_1, x_2)$ is zero in the second and fourth quadrants of the plane of (x_1, x_2) and so does not define a bivariate normal distribution. It is easy to show that the marginal density functions $f_i(x_i)$, $i=1, 2$, of the two variables are standardized normal density functions. For example,

$$f_1(x_1) = \begin{cases} \frac{1}{\pi}\int_0^\infty \exp[-\frac{1}{2}(x_1^2 + x_2^2)]dx_2 = \frac{1}{\sqrt{2\pi}}\exp(-\frac{1}{2}x_1^2) & \text{if } x_1 \geqq 0 \\ \frac{1}{\pi}\int_{-\infty}^0 \exp[-\frac{1}{2}(x_1^2 + x_2^2)]dx_2 = \frac{1}{\sqrt{2\pi}}\exp(-\frac{1}{2}x_1^2) & \text{if } x_1 \leqq 0. \end{cases}$$

The two random variables u_1 and u_2 defined by

$$(2)\qquad \begin{cases} u_1 = (x_1 + x_2)/\sqrt{2} \\ u_2 = (x_1 - x_2)/\sqrt{2} \end{cases}$$

are not jointly normally distributed. To see this we need only notice that (2) defines a 45° rotation of axes in the plane such that the joint density function $g(u_1, u_2)$ of u_1 and u_2 will have the form $\pi^{-1}\exp[-\frac{1}{2}(u_i^2+u_2^2)]$ in two quarter planes which are bisected by the axis of u_1 and in the other two quarter planes $g(u_1, u_2)=0$.

The marginal distribution of the random variable u_1 is not normal, since its density function is given by

$$g_1(u_1) = \begin{cases} \frac{1}{\pi}\int_{-u_1}^{u_1} \exp[-\frac{1}{2}(u_1^2 + u_2^2)]du_2 & \text{if } u_1 \geqq 0 \\ \frac{1}{\pi}\int_{u_1}^{-u_1} \exp[-\frac{1}{2}(u_1^2 + u_2^2)]du_2 & \text{if } u_1 < 0. \end{cases}$$

From the above one obtains

$$(3)\qquad g_1(u_1) = \sqrt{\frac{2}{\pi}}\exp(-\tfrac{1}{2}u_1^2)[\Phi(|u_1|) - \Phi(-|u_1|)],$$

where $\Phi(x)$ denotes the cumulative of the standardized normal distribution. Since $E(u_1)=0$, if (3) were a normal density function, the bracketed expression

would reduce to the form $c\cdot\exp(-ku_1^2)$ for some constants c and k with $c>0$ and $k\geqq 0$. But

$$\Phi(|u_1|) - \Phi(-|u_1|) = (2\pi)^{-1/2}\int_{-|u_1|}^{|u_1|}\exp(-\tfrac{1}{2}u_2^2)du_2$$
$$= \sqrt{\frac{2}{\pi}}\sum_{n=0}^{\infty}\frac{(-1)^n|u_1|^{2n+1}}{n!(2n+1)2^n}$$

and this power series does not have the appropriate form to be the expansion of $c\cdot\exp(-ku_1^2)$.

INTEGRATION, ANTI-DIFFERENTIATION AND A CONVERSE TO THE MEAN VALUE THEOREM

HOWARD LEVI, Hunter College, City University of New York

While preparing a revision of his experimental course in analysis [1] the writer came upon a theorem which could also be of use in other revisions of the calculus course. The theorem is the following converse to the Mean Value Theorem.

THEOREM. *Let F and f be real valued functions defined on the open interval I and let f be continuous there. Suppose that for every x and y of I there is a z between x and y such that $F(x)-F(y)=(x-y)f(z)$. Then F is differentiable on I and f is its derivative.*

While this theorem does not seem to be in the literature no detailed proof is needed here, since the result is a direct consequence of the definition of derivative and continuity. The writer does wish to comment on some of its implications for the teaching of calculus.

The principal implication is that it makes it possible to bypass the definite integral in the first study of calculus. At present the usual sequence of events is: (a) The definite integral is defined and studied; (b) the fundamental theorem about its evaluation by the indefinite integral is taken up, and (c) applications are given. These take the form of recognizing that certain quantities such as area, arc length, mass, work, etc., can be defined or otherwise expressed as definite integrals and hence can often be evaluated by anti-differentiation. The theorem in question makes it possible to omit steps (a) and (b) and begin at once with the applications. This is so because the same information which permits the formulation of the quantity in question as the definite integral $F(x)-F(y)=\int_y^x f(t)dt$ implies that $F(x)-F(y)$ is between $(x-y)$ max f and $(x-y)$ min f.

Hence, if f is continuous, the theorem identifies f as the derivative of F directly.

Of course even if it is conceded that bypassing the definite integral is possible it might be maintained that such a step is undesirable. The writer's considered opinion on this question is: (a) the material in this topic is so difficult that the student is almost always presented with a frankly incomplete treatment, an incorrect treatment or an incomprehensible treatment; (b) at this level all the functions are piece-wise analytic and require neither the generality nor the subtlety of the usual approach.

The theorem can also be applied meaningfully if F is given and f is unknown. For instance, to identify speed as ds/dt we usually tell our students that this is how the physicists do or should define it. While it is true that many physicists are adept in the use of limits, it is not reasonable to presuppose this skill in practitioners of other disciplines in which calculus can play a role. An alternative approach, using speed as an example, would be to note that we could plausibly expect $\Delta t \cdot \min$ speed to underestimate distance and $\Delta t \cdot \max$ speed to overestimate it. The theorem then asserts that, however speed is defined, ds/dt is a correct formula for it in the usual situations.

DEFINITION OF RADIUS OF CONVERGENCE

D. E. MYERS, University of Arizona

In most calculus texts, the standard definition of the radius of convergence of a power series

$$a_0 + a_1x + a_2x^2 + \cdots + a_nx^n + \cdots \tag{1}$$

is

$$r = \lim_{n\to\infty} \left| \frac{a_n}{a_{n+1}} \right|.$$

With this definition the problems are carefully selected so that the limit always exists. In addition to obtaining a certain skill in computing this limit, the student is asked to grasp two more subtle ideas. On the one hand, r is represented intuitively as maximal such that the series converges for all x with $|x| < r$ and then, somewhat in contrast, the student is cautioned to check independently for convergence at the end points of the interval. Often, to enforce the student's retention of this latter concept, the examples and problems are so chosen that divergence occurs in at least one of the end points. As a consequence, many students expect that this will always occur.

At the next level, perhaps in an advanced calculus or introductory analysis

course, the radius of convergence is generally defined by the root-test whereby the problems of existence of the limit are avoided. The computation of r still seems to rely, however, on the ratio test with "Lim" replaced by "Lim Sup"; consequently, the student still thinks of radius of convergence in terms of maximal region of convergence or the value of

$$\operatorname*{Lim\,Sup}_{n\to\infty}\left|\frac{a_n}{a_{n+1}}\right|.$$

The student next encounters the same problem in the context of complex variable theory complicated by the study of singularities. At this point, the circle of convergence becomes identified with the location of the singularities of the function represented by the series.

We come now to a very interesting example, intended to justify the preceding discussion. Let $f(z)=\sum_{n=1}^{\infty} z^n/n^2$. It is easily seen that the series converges not only for $|z|<1$ but for $|z|=1$. The student wonders where the singularities of f are. If r represents the maximum such that convergence occurs for $|z|<r$, why is the radius for this example 1 and not $1+\epsilon$ ($\epsilon>0$)? The answer is that in this case the singularity is manifested not at a point of divergence, but rather in the nondifferentiability of f. The singularity is easily found by testing the convergence of the differentiated series. It occurs at $z=1$. Of course, if one differentiates the series twice then the resulting series diverges at every point on the circle $|z|=1$.

A FOURIER SERIES DERIVATION OF THE EULER-LAGRANGE EQUATION

RICHARD MENZEL, Haile Sellassie I University

THEOREM. *Suppose that* $y=\bar{y}(x)$ *extremizes* $\int_a^b f(x, y(x), y'(x))dx$ *with respect to all functions which are continuously differentiable on* $[a, b]$ *and which satisfy* $y(a)=y_1$, $y(b)=y_2$. *Then there is a constant* c *such that*

$$f_{y'}(x, \bar{y}(x), \bar{y}'(x)) - \int_a^x f_y(x, \bar{y}(x), \bar{y}'(x))dx = c \qquad \text{for all } x \text{ in } [a, b].$$

Proof. (We assume that $f(x, y, y')$, $f_y(x, y, y')$ and $f_{y'}(x, y, y')$ are continuous for all x in $[a, b]$ and for all y and y'.) We may work over the interval $[-\pi, \pi]$ rather than over $[a, b]$ without loss of generality. Let $I_n(\alpha)=\int_{-\pi}^{\pi} f(x, \bar{y}+\alpha \sin nx, \bar{y}'+\alpha n \cos nx)dx$ for $n=1, 2, 3, \cdots$. Since $\bar{y}(x)$ extremizes $\int_{-\pi}^{\pi} f(x, y(x), y'(x))dx$ with respect to all continuously differentiable functions having the appropriate end-point conditions, it extremizes $I_n(\alpha)$ with respect to functions of the form $\bar{y}+\alpha \sin nx$ for $n=1, 2, 3, \cdots$. Hence

$$I_n'(0) = 0 = \int_{-\pi}^{\pi} [f_y(x, \bar{y}, \bar{y}') \sin nx + f_{y'}(x, \bar{y}, \bar{y}')n \cos nx]dx$$

$$= \int_{-\pi}^{\pi} \left[- \int_{-\pi}^{x} f_y(x, \bar{y}(x), \bar{y}'(x))dx + f_{y'}(x, \bar{y}(x), \bar{y}'(x)) \right] n \cos nx dx.$$

The function

$$- \int_{-\pi}^{x} f_y(x, \bar{y}(x), \bar{y}'(x))dx + f_{y'}(x, \bar{y}(x), \bar{y}'(x))$$

has a corresponding Fourier series

$$a_0/2 + \sum_{1}^{\infty} (a_i \cos ix + b_i \sin ix)$$

and

$$I_n'(0) = \int_{-\pi}^{\pi} \left[a_0/2 + \sum_{i}^{\infty} (a_i \cos ix + b_i \sin ix) \right] n \cos nx dx = n a_n \pi = 0$$

for $n = 1, 2, 3, \cdots$.

Hence $a_n = 0$ for $n = 1, 2, 3, \cdots$. Similarly we define

$$J_n(\alpha) = \int_{-\pi}^{\pi} f(x, \bar{y} + \alpha(\cos nx - (-1)^n), \bar{y}' - \alpha n \sin nx)dx \quad \text{for } n = 1, 2, 3, \cdots$$

and note that

$$\begin{aligned} J_n'(0) &= \int_{-\pi}^{\pi} [f_y(x, \bar{y}, \bar{y}')(\cos nx - (-1)^n) + f_{y'}(x, \bar{y}, \bar{y}')(-n \sin nx)]dx \\ &= \int_{-\pi}^{\pi} \left[- \int_{-\pi}^{x} f_y(x, \bar{y}, \bar{y}')dx + f_{y'}(x, \bar{y}, \bar{y}') \right] (-n \sin nx)dx \\ &= \int_{-\pi}^{\pi} \left[a_0/2 + \sum_{1}^{\infty} b_i \sin ix \right] (-n \sin nx)dx = - n b_n \pi = 0 \end{aligned}$$

and hence that $b_n = 0$ for $n = 1, 2, 3, \cdots$. Since

$$- \int_{-\pi}^{x} f_y(x, \bar{y}(x), \bar{y}'(x))dx + f_{y'}(x, \bar{y}(x), \bar{y}'(x))$$

is a continuous function on the closed interval $[-\pi, \pi]$, it equals its constant Fourier series there.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, Louisiana State University; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P. O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be submitted legibly on separate, signed sheets and should be mailed before September 30, 1967. Any contributor wishing acknowledgement of his solution should include a self-addressed, stamped postcard. (Solvers outside the United States may omit the stamp.)

E 1985. *Proposed by E. O. Buchman, University of California, Los Angeles*

The functions $t(m)$ are defined recursively by $t(0)=1$, $t(m+1)=\sum_{i=0}^{m}\binom{m}{i}t(i)$, $i=1, 2, \cdots$. Show that $t(m)$ is the number of elements in the set $T_m=\{(a_1, \cdots, a_m)\colon a_i \text{ is a positive integer, } a_1=1,\ a_i\leqq 1+\max_{k<i}a_k\}$. See E 1785 [1966, 672].

E 1986. *Proposed by H. S. Shapiro, New York University*

Let B denote the set $\sum_{i=1}^{n}x_i^2\leqq 1$ in Euclidean n-space. Suppose f is a differentiable function on an open set containing B, and that $|f(x)|\leqq 1$ for $x=(x_1, \cdots, x_n)\in B$. Then show that there is a point interior to B at which grad f has a magnitude less than 4.

E 1987. *Proposed by Joseph Arkin, Suffern, N. Y.*

Show that there are infinitely many solutions of

$$(a/b)^2+(b/a)^2-(x/y)^2-(y/x)^2=L^2,$$

where $L(\neq 0)$ is a rational number and each of a, b, x, y is the sum of squares of two integers.

E 1988. *Proposed by R. S. Luthar, Colby College, Waterville, Me.*

Given any integers a, k, $a\geqq k\geqq 0$, show that, for each positive integer n there exists an integer b such that

$$\lfloor\sqrt{a}-\sqrt{(a-k)}\rfloor^n=\sqrt{b}-\sqrt{(b-k^n)}.$$

E 1989. *Proposed by W. A. McWorter, University of British Columbia*

Define a generalized map on the plane to be a partition of the plane into a finite family of pairwise disjoint, nonempty, connected sets. These sets are called countries. We say two countries are adjacent if their union is connected.

Prove or disprove that such a map on the plane can be colored in five colors so that no two adjacent countries have the same color. What happens if we replace "connected" with "arcwise connected"?

E 1990. *Proposed by V. F. Ivanoff, San Carlos, California*

Given a pentagon with the sides 1, 2, $\cdots$, 5 in that order. Denoting by $p(q:r)$ the segment on the side p intercepted by the sides q and r, prove that

$$\text{(a)}\ \prod[1(3:5)] = \prod[5(1:3)], \qquad \text{(b)}\ \prod[1(4:5)] = \prod[5(1:2)],$$

where each factor is obtained by increasing the numbers of its predecessor by 1, the resulting numbers to be taken modulo 5. (Note: Both statements have been proved for cyclic pentagons. See W. B. Carver, *Cyclic Polygons*, this MONTHLY, 68 (1961) 537, with two illustrations.)

E 1991. *Proposed by J. M. Khatri, Baroda, India*

Find integral solutions of $(a^2-x)(b^2-x)=c^2-x$.

E 1992. *Proposed by Eric Mendelsohn, University of Manitoba*

If we define a generalized nth derivative as $f^{(n)}(x)=\lim_{h\to 0}\Delta^n f/h^n$, where $\Delta f=f(x+h)-f(x)$, we have

$$f''(x) = \lim\,[f(x+2h) - 2f(x+h) + f(x)]/h^2,$$

etc. Is there a function which is infinitely differentiable at a limit point of its discontinuities?

E 1993. *Proposed by R. O. Davies and A. J. Wiseman, the University, Leicester, England*

Prove that for $n=1, 2, \cdots$, the following $(n+1)\times(n+1)$ determinant vanishes:

$$\begin{vmatrix}
1 & 2\binom{2n-1}{1} & 2^2\binom{2n-1}{2} & \cdots & 2^n\binom{2n-1}{n} \\
1 & \binom{n+1}{1} & \binom{n+1}{2} & \cdots & \binom{n+1}{n} \\
0 & 1 & \binom{n+1}{1} & \cdots & \binom{n+1}{n-1} \\
0 & 0 & 1 & \cdots & \binom{n+1}{n-2} \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & 0 & \cdots & \binom{n+1}{1}
\end{vmatrix}.$$

E 1994. *Proposed by T. M. K. Davison, University of Waterloo, Ontario*

Let $\{\alpha_n\}$ be a sequence of positive numbers. Put $a_1=1$, $a_{n+1}=a_n+\alpha_n a_n^{-1}$ for $n\geqq 1$. Prove that as $n\to\infty$, $\lim a_n$ exists if and only if $\sum_{n=1}^{\infty}\alpha_n$ is finite.

SOLUTIONS OF ELEMENTARY PROBLEMS

A Variant of Langford's Problem

E 1845 [1966, 81]. *Proposed by R. S. Nickerson, Hanscom Field, Bedford, Mass.*

Consider a sequence of integers in which: (a) every integer, i, $0<i\leqq n$, occurs exactly twice, and (b) the second occurrence of the integer, i, follows its first occurrence by exactly i integers. For example, for $n=5$, the sequence 3, 5, 2, 3, 2, 4, 5, 1, 1, 4 satisfies these conditions.

For arbitrary n, (1) state a rule determining whether or not at least one such sequence exists, (2) describe a procedure for generating such a sequence if it exists, and (3) state a rule for determining how many such sequences exist.

Solution by D. C. B. Marsh, Colorado School of Mines. (1) At least one such sequence exists if and only if $n\equiv 0$ or 1 (mod 4). For, if the positions are labelled from 1 to $2n$, then if "1" occupies positions p_1 and p_1+1, and if "2" occupies positions p_2 and p_2+2, $\cdots$, and if "n" occupies positions p_n and p_n+n, summing we find that $2\sum p_i+\frac{1}{2}n(n+1)=n(2n+1)$, whence $\frac{1}{4}(3n^2+n)=\sum p_i$ must be integral, whence $n\equiv 0$ or 1 (mod 4) is necessary. Sufficiency is shown in (2).

(2) For $n=4t$, possible positions for the integers 1, 2, $\cdots$, n are as shown:

Integer	*Position*	*Integer*	*Position*	*Integer*	*Position*
$4t$	$1,\ 4t+1$	$2t-1$	$4t+2,\ 6t+1$	$2t-3$	$5t+2,\ 7t-1$
$4t-2$	$2,\ 4t$			$2t-5$	$5t+3,\ 7t-2$
$4t-4$	$3,\ 4t-1$	$4t-3$	$4t+3,\ 8t$		
.		$4t-5$	$4t+4,\ 8t-1$	3	$6t-1,\ 6t+2$
2	$2t,\ 2t+2$				
		$2t+1$	$5t+1,\ 7t+2$		
$4t-1$	$2t+1,\ 6t$				
1	$7t,\ 7t+1$				

Note: if $t=2$, omit the third column; if $t=1$, omit both the second and third columns.

E.g., 42324311, 8642724683573115, (12)(10)8642(11)2468(10)(12) 5973(11) 531179, (16)(14)(12)(10)8642(15)2468(10)(12)(14)(16)7(13)(11)953(15)735119 (11)(13).

For $n=4t+1$. $n=5$ has been illustrated. For $t>1$,

Integer	*Position*	*Integer*	*Position*	*Integer*	*Position*
$4t$	$1,\ 4t+1$	$4t-1$	$4t+2,\ 8t+1$	$2t-3$	$5t+4,\ 7t+1$
$4t-2$	$2,\ 4t$	$4t-3$	$4t+3,\ 8t$	$2t-5$	$5t+5,\ 7t$
.					
2	$2t,\ 2t+2$	$2t+1$	$5t+1,\ 7t+2$	3	$6t+1,\ 6t+4$
		$2t-1$	$6t+3,\ 8t+2$		
$4t+1$	$2t+1,\ 6t+2$				
		1	$5t+2,\ 5t+3$		

where, for $t=2$, the third column is to be omitted.

E.g., 864292468751193573, (12)(10)8642(13)2468(10)(12)(11)97113(13)5379(11)5.

(3) A finite algorithm for determining the number of such sequences is the following. Let S be the set $\{1, 2, \cdots, 2n\}$. Choose $p_1 \in S$ (letting p_1 run from 1 through $2n$). Compute p_1+1. If p_1+1 is not in S, no sequence exists. If $p_1+1 \in S$, choose any p_2 in $S_1 = S - \{p_1, p_1+1\}$. Compute p_2+2. If $p_2+2 \notin S_1$, no sequence exists; if $p_2+2 \in S_1$, choose any p_3 in $S_2 = S_1 - \{p_2, p_2+2\}$. Continue until S is exhausted.

NOTE: Langford's problem (which differs from the above in requiring i integers in the series *between* the two occurrences of i) was proposed in Math. Gaz., 42 (1958), p. 228. Solutions were given by Priday and Davies in the next volume, pp. 250–255. A generalization, for which no solutions have been discovered, was proposed by Gillespie and Utz in the Fibonacci Quarterly, **4** (1966), p. 184–186. (References supplied by Douglas Lind.)

Also solved by Michael Goldberg.

Fibonacci Polynomials

E 1846 [1966, 81]. *Proposed by M. N. S. Swamy, University of Saskatchewan*

Show that the Fibonacci polynomials defined by

$$f_n(x) = x \cdot f_{n-1}(x) + f_{n-2}(x), \qquad f_1 = 1, \qquad f_2 = x,$$

satisfy the inequality $f_n^2(x) \leqq (x^2+1)^2 \cdot (x^2+2)^{n-3}$, $n > 2$.

Solution by R. E. Giudici, Student, University of Pittsburgh. For every real x, the relation

$$x(x^2+2)^{-1/2} + (x^2+2)^{-1} < 1, \tag{1}$$

follows immediately from $x^4+2x^2 < (x^2+1)^2$. Since $f_3 = x^2+1$, the proposed inequality is plainly satisfied for $n=3$. We proceed by induction assuming

$$f_k^2(x) \leqq (x^2+1)^2 \cdot (x^2+2)^{k-3}, \qquad k > 2.$$

We then have

$$f_{k+1}^2(x) = [xf_k(x) + f_{k-1}(x)]^2$$
$$\leqq [x(x^2+1)(x^2+2)^{(k-3)/2} + (x^2+1)(x^2+2)^{(k-4)/2}]^2$$
$$\leqq (x^2+1)^2(x^2+2)^{k-2}[x(x^2+2)^{-1/2} + (x^2+2)^{-1}]^2.$$

Taking into account (1), this proves $f_{k+1}^2(x) \leqq (x^2+1)^2(x^2+2)^{k-2}$ and the proof is complete.

Also solved by C. A. Bridger, J. L. Brown, Jr., John Burslem, M. S. Demos, Mrs. A. C. Garstang, E. D. Gingerich, Sylvan Green, Emil Grosswald, Richard Guilfoyle, M. H. Hayamizu, A. E. A. Hunt, Erwin Just, D. A. Klarner, Kenneth Kramer, Jeffrey Kuester, R. N. Leggett, Jr., G. A. Luester, Beatriz Margolis, D. C. B. Marsh, M. F. Neuts, Stanton Philipp, Robert Prielipp, George Purdy (England), Stanley Rabinowitz, L. A. Ringenberg, V. K. Rohatgi, P. A. Scheinok, M. J. Schweitzer, A. Sharma & A. Meir, R. J. Snelling, W. J. Sonsin, Stephen Spindler, Sidney Spital, J. E. Wilkins, Jr., Dale Woods, David Zeitlin, and the proposer.

Guilfoyle shows that $f_n(x)$ is the $(n-1)\times(n-1)$ determinant

$$\begin{vmatrix} x & -1 & 0 & 0 & \cdots & & & & \\ 1 & x & -1 & 0 & \cdots & & & & \\ 0 & 1 & x & -1 & \cdots & & & & \\ \cdots & & & & & & & & \\ & & & & & 1 & x & -1 & \\ & & & & & 0 & 1 & x & \end{vmatrix}$$

from which the result follows by Hadamard's inequality. See: P. Davis, *Interpolation and Approximation*, New York, 1963.

Bridger gives a reference to P. F. Byrd, *Expansion of analytic functions in polynomials associated with Fibonacci numbers*, in The Fibonacci Quarterly, I(1963), pp. 16–28, for those wishing to pursue the subject further.

Lagrange Polynomials

E 1848 [1966, 82]. *Proposed by J. F. Traub, Bell Telephone Laboratories, Murray Hill, N. J.*

Let $P(t)$ be a polynomial of degree n with distinct zeros $\rho_1, \rho_2, \cdots, \rho_n$. We know from interpolation that

$$P'(t) = \sum_{i=1}^{n} P'(\rho_i)L_i(t),$$

where $L_i(t)$ is the Lagrange polynomial

$$L_i(t) = \frac{P(t)}{P'(\rho_i)(t-\rho_i)}.$$

Prove also that $P'(t) = \sum_{i=1}^{n} P'(\rho_i)L_i^2(t)$.

Solution by David Zeitlin, Minneapolis, Minn. Let $P(t) = \prod_{i=1}^{n}(t-\rho_i)$. Then, using partial fractions,

$$\frac{1}{P(t)} = \sum_{i=1}^{n} \frac{1}{P'(\rho_i)} \cdot \frac{1}{(t-\rho_i)}. \tag{1}$$

If we differentiate (1) with respect to t, we obtain

$$P'(t) = \sum_{i=1}^{n} \frac{P^2(t)}{P'(\rho_i)(t-\rho_i)^2} \equiv \sum_{i=1}^{n} P'(\rho_i) L_i^2(t),$$

since $P^2(t) \equiv L_i^2(t)(P'(\rho_i))^2(t-\rho_i)^2$.

Also solved by L. Carlitz, M. M. Chawla (India), H. E. Fettis, P. G. Kirmser, Kenneth Kramer & Joel Spruck, R. N. Leggett, Jr., D. C. B. Marsh, Stanton Philipp, Stanley Rabinowitz, A. Sharma, Sidney Spital, I. Vrečko (Yugoslavia), J. E. Wilkins, Jr., K. L. Yocom, P. H. Young, and the proposer.

Identity in sinh x and cosh x

E 1849 [1966, 82]. *Proposed by George Purdy, The University, Reading, England*

Let $f_0(x) = \cosh x$, $f_1(x) = \sinh x$. Then for $r = 0$, 1 and $m \geqq 1$,

$$f_r(x_1 + x_2 + \cdots + x_m) = \sum f_{s_1}(x_1) \cdots f_{s_m}(x_m)$$

identically, where the summation is taken over all choices of $s_1, \cdots, s_m$, each being 0 or 1, with $s_1 + \cdots + s_m \equiv r \pmod 2$. A proof is desired which does not employ mathematical induction.

Solution by M. F. Neuts, Purdue University. We have

$$f_0(x) + f_1(x) = e^x, \qquad f_0(x) - f_1(x) = e^{-x}.$$

So

$$e^{\pm(x_1+\cdots+x_m)} = \prod_{i=1}^{m} [f_0(x_i) \pm f_1(x_i)].$$

By adding and subtracting these two equations, the required identities are obtained, since all terms for which the subscripts do not satisfy the stated congruence cancel out.

Also solved by John Burslem, L. Carlitz, D. C. B. Marsh, R. C. Fisher, Stanley Rabinowitz, I. Vrečko (Yugoslavia), and the proposer.

An Integral Equal to $\sigma(n)$

E 1850 [1966, 82]. *Proposed by George Purdy, The University, Reading, England*

Prove the following formula in which $\sigma(n)$ is the sum of the divisors of the positive integer n, and $[x+1]$ denotes the integral part of $x+1$:

$$\sigma(n) = \sum_{m=1}^{n} \int_0^m \cos\left(\frac{2\pi n[x+1]}{m}\right) dx.$$

Solution by J. L. Brown, Jr., Pennsylvania State University. We have

$$\int_0^m \cos\left(\frac{2\pi n[x+1]}{m}\right)dx = \sum_{k=1}^{m}\int_{k-1}^{k} \cos\left(\frac{2\pi n}{m}\right)k\,dx$$
$$= \sum_{k=1}^{m} \cos k\left(\frac{2\pi n}{m}\right).$$

Using the well-known result

$$\sum_{k=1}^{m} \cos kx = \cos\left(\frac{m+1}{2}x\right)\sin\frac{mx}{2} \Big/ \sin\frac{x}{2},$$

we find

$$\int_0^m \cos\left(\frac{2\pi n[x+1]}{m}\right)dx = \begin{cases} m & \text{if } m \mid n \\ 0 & \text{if } m \nmid n, \end{cases}$$

from which the result follows.

Also solved by I. K. Abroub, M. S. Demos, R. B. Eggleton (Australia), M. G. Greening (Australia), Stephen Hoffman, Peter Landesman & Sylvie Vandermousen, R. N. Leggett, Jr., C. C. Lindner, D. C. B. Marsh, Haynes Miller, Lieselotte Miller, Jorge More, M. F. Neuts, Stanton Philipp, Stanley Rabinowitz, S. M. Sarma & A. M. Vaidya (India), Perry Scheinok, R. J. Snelling, Al Somayajulu, Stephen Spindler, Sidney Spital, P. C. Yang, and the proposer.

Diagonal in a Rectangle of Unit Squares

E 1851 [1966, 82]. *Proposed by W. E. Patten, South Boston, Va.*

In problem E 1704 [1965, 669] it was found that if an $m\times n$ rectangle is partitioned into mn unit squares in the natural way, then the number of these which meet a diagonal of the rectangle is $m+n-(m, n)$, where (m, n) is the g.c.d. of the positive integers m and n. Given the positive integer k, for how many rectangles does a diagonal meet precisely k unit squares?

Solution by Miltiades S. Demos, Drexel Institute of Technology. Set $(m, n)=d'$, $m=xd'$, $n=yd'$; $k=dd'$ since $d' \mid k$. Then the problem is equivalent to finding the number of solutions of $x+y-1=d$, $(x, y)=1$, for all divisors d of k. Then $(x, d+1)=1$, $(y, d+1)=1$ and the number of solutions is $\sum_{d\mid k}\phi(d+1)$ if we distinguish between rectangles $m\times n$ and $n\times m$. Otherwise, since there is exactly one square $(k\times k)$, the number is $\frac{1}{2}\{1+\sum_{d\mid k}\phi(d+1)\}$.

Also solved by Walter Bluger, John Burslem, L. Carlitz, R. B. Eggleton (Australia), Michael Goldberg M. G. Greening (Australia), D. C. B. Marsh, Norman Miller, and C. B. A. Peck.

Summations of Binomial Coefficients

E 1854 [1966, 83]. *Proposed by Rolf Schneider, The University, Frankfurt am Main, Germany*

Let p be an odd prime and k any positive integer. Show that

$$\sum_{i=0}^{(p^k-1)/2} (-1)^i \binom{2i}{i} \equiv 5^{k(p-1)/2} \pmod{p},$$

$$\sum_{i=0}^{(p^k-1)/2} \binom{2i}{i} \equiv (-3)^{k(p-1)/2} \pmod{p}.$$

Solution by Leonard Carlitz, Duke University. We have

$$5^{k(p-1)/2} \equiv 5^{(p^k-1)/2} \equiv (1+4)^{(p^k-1)/2} \equiv \sum_{j=0}^{\frac{1}{2}(p^k-1)} \binom{\frac{1}{2}(p^k-1)}{j} 4^j \pmod{p},$$

$$(-3)^{k(p-1)/2} \equiv (-3)^{(p^k-1)/2} \equiv \sum_{j=0}^{\frac{1}{2}(p^k-1)} (-1)^j \binom{\frac{1}{2}(p^k-1)}{j} 4^j \pmod{p}.$$

Hence it suffices to show that

$$4^j \binom{\frac{1}{2}(p^k-1)}{j} \equiv (-1)^j \binom{2j}{j} \pmod{p}.$$

We recall that if

$$a = a_0 + a_1 p + \cdots + a_r p^r \qquad (0 \leqq a_t < p)$$

$$b = b_0 + b_1 p + \cdots + b_r p^r \qquad (0 \leqq b_t < p),$$

then

$$(*) \qquad \binom{a}{b} \equiv \binom{a_0}{b_0}\binom{a_1}{b_1} \cdots \binom{a_r}{b_r} \pmod{p}.$$

Thus $j = j_0 + j_1 p + \cdots + j_{k-1} p^{k-1}$ $(0 \leqq j_t < p)$ implies

$$\binom{\frac{1}{2}(p^k-1)}{j} \equiv \binom{\frac{1}{2}(p-1)}{j_0}\binom{\frac{1}{2}(p-1)}{j_1} \cdots \binom{\frac{1}{2}(p-1)}{j_{k-1}}.$$

But

$$\binom{\frac{1}{2}(p-1)}{j} \equiv \binom{-\frac{1}{2}}{j} \equiv (-1)^j 2^{-2j} \binom{2j}{j} \pmod{p},$$

so that

$$\binom{\frac{1}{2}(p^k-1)}{j} \equiv (-1/4)^{j_0+\cdots+j_{k-1}} \binom{2j_0}{j_0}\binom{2j_1}{j_1} \cdots \binom{2j_{k-1}}{j_{k-1}}.$$

Note that unless each $j_t \leqq \frac{1}{2}(p-1)$, the product $\equiv 0$. Therefore, again using (*), we get, as required,

$$\binom{\frac{1}{2}(p^k-1)}{j} \equiv (-1/4)^j \binom{2j}{j} \pmod{p}.$$

Also solved by M. G. Greening (Australia).

Summation of Greatest Integer Functions

E 1856 [1966, 198]. *Proposed by S. W. Williams, Lehigh University*

Given n any positive integer, prove the identity

$$\sum_{k=1}^{n} [kx] = n[x] + \sum_{i=1}^{n-1} \sum_{k=1}^{i} \left[x + \frac{k}{i+1} \right],$$

where, as usual, $[x]$ is the greatest integer in x.

Solution by Henry Ricardo, Yeshiva University. It is known that

$$\sum_{i=0}^{k-1} \left[x + \frac{i}{k} \right] = [kx],$$

(easily proved; see, e.g., Pólya and Szegö, *Aufgaben und Lehrsätze aus der Analysis*, II, sec. viii, problem 9). Therefore

$$\sum_{k=1}^{n} [kx] = \sum_{k=1}^{n} \sum_{i=0}^{k-1} \left[x + \frac{i}{k} \right]$$

$$= n[x] + \sum_{k=2}^{n} \sum_{i=1}^{k-1} \left[x + \frac{i}{k} \right] = n[x] + \sum_{k=1}^{n-1} \sum_{i=1}^{k} \left[x + \frac{i}{k+1} \right].$$

Also solved by J. C. Abad, A. N. Aheart, R. B. Eggleton (Australia), A. L. Epstein, R. W. Feldmann, M. G. Greening (Australia), Stephen Hoffman, J. E. Homer, Jr., Edward Hook, F. T. Howard, M. S. Klamkin, J. D. E. Konhauser, E. S. Langford, Arthur Lieberman, D. C. B. Marsh, Lieselotte Miller, Norman Miller, Stanton Philipp, Stanley Rabinowitz, Jürg Rätz (Switzerland), Simeon Reich (Israel), Judy Richman, M. S. R. K. Sastry, Perry Scheinok, Robert Schreiner, Al Somayajulu, Sidney Spital, David Zeitlin, and the proposer.

Commutativity of Addition

E 1858 [1966, 198]. *Proposed by S. E. Dickson, University of Nebraska*

Assume the usual properties of the real numbers except for commutativity of addition. Given that the equation $x+y=y+x$ holds for real numbers x and y less than 10^{-26} apart, show that this latter restriction can be removed.

Solution by Margaret W. Taft, student, Clark University. Suppose $|a-b| < k$, a and b real; and let $\epsilon > 0$ be arbitrarily small. We have $\epsilon|a-b|/(k+1) < \epsilon$. By the distributive law, $|\epsilon a/(k+1) - \epsilon b/(k+1)| < \epsilon$, whence, by hypothesis,

$$\frac{\epsilon a}{k+1} + \frac{\epsilon b}{k+1} = \frac{\epsilon b}{k+1} + \frac{\epsilon a}{k+1}, \qquad \frac{\epsilon}{k+1}(a+b) = \frac{\epsilon}{k+1}(b+a).$$

Thus $a+b=b+a$ for all real a and b.

Also solved by Joe Beckely, J. L. Brown, Jr., J. P. Celenza, C. W. Dodge, G. F. Feissner, Arne Garness & G. A. Heuer, E. D. Gingerich, Anton Glaser, H. D. Gunghenn, Erwin Just, R. S. Kaluzniacki D. C. B. Marsh, Norman Miller, D. E. Nixon & J. P. Thomas, Robert Prener, Azriel Rosenfeld, G. F. Schumm, E. J. Wegman, John Wessner, P. C. Yang, and the proposer.

Rosenfeld notes that the conclusion follows even if the second sentence of the statement is omitted; see Problem E 1812 [1967, 199]. Dodge found an equivalent result in H. Eves, *An Introduction to the Foundations and Fundamental Concepts of Mathematics*, Rev. ed., p. 313.

Characteristic Roots of a Matrix

E 1859 [1966, 198]. *Proposed by Judith H. Hallman, University of North Carolina and Western Electric Company*

Let $k_1, k_2, \cdots, k_n$ be any real numbers different from zero and let $A=(a_{ij})$ be the matrix $a_{ij}=k_i/k_j$. Find the n characteristic roots of A.

I. *Solution by D. E. Crabtree, Amherst College.* Let D be the diagonal matrix $D=\text{diag}\ (k_1, k_2, \cdots, k_n)$. Then A is similar to the matrix $D^{-1}AD$, each entry of which is 1. Thus the characteristic roots of A are 0 (with multiplicity $n-1$) and n. Of course, the restriction that the k_i be real is unnecessary.

II. *Solution by P. G. Kirmser, Kansas State University.* The matrix A is the matrix M of Problem E 1685 [1965, 321], where the characteristic roots are found to be 0, of multiplicity $n-1$, and n, of multiplicity 1.

Also solved by H. D. Abramson, W. R. Allaway, J. F. Burke, J. P. Celenza, P. L. Claypool, R. W. Feldmann, R. O. Fisher, A. V. Geramita, M. G. Greening (Australia), R. S. Kaluzniacki, E. S. Langford, Arthur Lieberman, D. C. B. Marsh, Dave Nixon, Stanton Philipp, Stanley Rabinowitz, July Richman, Steven Russ, R. Sivaramakrishnan (India), J. B. Skinner, Sidney Spital, Rory Thompson, John Wessner, H. H. Wong, and the proposer.

ADVANCED PROBLEMS

All solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of advanced problems in this issue should be submitted on separate, signed sheets and should be mailed before November 30, 1967. Any contributor wishing acknowledgement of his solution should include a self-addressed stamped postcard. (Solvers outside the United States may omit the stamp.)

Let L_1 and L_2 denote those sets of measurable real-valued functions which are Lebesgue integrable and square integrable, respectively, on the interval $[0, 1]$. Prove that $f\in L_2$ if and only if (1) $f\in L_1$ and (2) there exists a nondecreasing function, h, such that for every

$$[r, s] \subset [0, 1], \qquad \left| \int_r^s f \right|^2 \leqq [h(s) - h(r)][s - r].$$

5491. *Proposed by Roy O. Davies and Roy Buckley, The University, Leicester, England*

Determine the coefficients $C_{n\nu}$ in the expansion

$$\int_\alpha^{\pi/2} \frac{\sin\,(2n+1)\psi}{\sqrt{(\cos^2\alpha - \cos^2\psi)}}\,d\psi = \sum_{\nu=0}^{n} C_{n\nu}\cos^{2\nu}\alpha \qquad (0 < \alpha < \tfrac{1}{2}\pi).$$

5492. *Proposed by S. B. Akers and R. D. Berlin, General Electric Company, Syracuse, N. Y.*

A $4k-1$ step symmetric random walk is performed by A along the x-axis starting at the origin. He is accompanied by B through the first $2k-1$ steps; thereafter each of B's steps is taken opposite in direction to the corresponding step taken by A. What is the probability that at the termination of the walk A and B will be on opposite sides of the origin?

5493. *Proposed by H. S. Shapiro, New York University*

Let $f(x, y)$ denote a cubic polynomial in x, y (i.e. a combination of monomial terms x^iy^j with $i+j\leqq 3$). Suppose the surface $z=f(x, y)$ has three saddle points and a local maximum at points S_1, S_2, S_3, and M respectively. Then M lies inside the triangle $S_1S_2S_3$.

5494. *Proposed by József Dénes and Raisz Klára, Central Research Institute for Physics, Budapest, Hungary*

If two permutations of degree $n(n\geqq 3)$ having at least two fixed elements are similar then they belong to the same conjugate class of the alternating group of degree n.

5495. *Proposed by Erwin Just, Bronx Community College, New York*

Let f and g be real-valued continuous functions defined on $[0, 1]$. If no linear combination of f and g has more than one zero in $(0, 1)$, and $f(0)g(1)\neq g(0)f(1)$, prove that some linear combination of f and g does not have any zeros in (0. 1).

5496. *Proposed by R. H. Shudde and E. S. Langford, U. S. Naval Postgraduate School*

Let B be any $m\times m$ matrix over the integers, with B^* the adjoint matrix of B. Prove that every $s\times s$ subdeterminant of B^* is divisible by $(\det B)^{s-1}$.

5497. *Proposed by Peter Yff, American University, Beirut, Lebanon*

Prove or disprove the following conjecture: If $A+B+C=\pi$, and $\cot\omega=\cot A+\cot B+\cot C$, then $8\omega^3\leqq ABC$, with equality only when $A=B=C$. ω is the Brocard angle.

5498. *Proposed by J. A. Hildebrandt, Louisiana State University*

Let S be a semigroup with at least three elements and $x\in S$ such that $S\backslash x$ is a group. Prove that S is regular if and only if x is a zero or an identity.

5499. *Proposed by D. E. Daykin, University of Malaya, Kuala Lumpur, and J. S. Biggerstaff, Portland, Oregon*

(1) Are there rational numbers a, b such that no rational numbers c, k exist for which there is a triangle having sides a, b, c and area k?

(2) Prove or disprove the conjecture: for every positive rational number k

there exist positive rational a, b, c such that a triangle with sides a, b, c has area k (e.g. triangle with sides 3/2, 5/3, 17/6 has area 1).

SOLUTIONS OF ADVANCED PROBLEMS

Converse of Weierstrass' M-test?

5390 [1966, 547]. *Proposed by D. W. Hight, Kansas State College, Pittsburg*

Is there a series $\sum_{i=0}^{\infty} u_i(x)$ of functions continuous on a closed interval $[a, b]$ that converges absolutely and uniformly for which the Weierstrass M-test fails?

I. *Solution by B. L. D. Thorp, York University, Toronto, Canada.* Let C denote the Banach space of continuous real or complex-valued functions on $[a, b]$ with the norm $\|u\| = \sup \{ |u(x)| : a \leqq x \leqq b \}$ $(u \in C)$. Since C is an infinite dimensional space there exists, by a theorem of A. Dvoretzky and C. A. Rogers (*Absolute and unconditional convergence in normed linear spaces*, Proc. Nat. Acad. Sci. (U.S.A.), 36(1950), 192–197) a series $\sum_{n=1}^{\infty} U_n(x)$ in C satisfying

(a) the series is convergent with respect to the norm in C (i.e. the series is uniformly convergent),

(b) any rearrangement of the series is uniformly convergent (i.e. the series is uniformly and absolutely convergent),

(c) $\sum_{n=1}^{\infty} \|U_n\|$ diverges.

For a simple example on $[0, 1]$ let the function $u_k(x)$ be defined by

$u_k(x) = 0$ if $0 \leqq x \leqq 1/(2k+1)$ or $1/(2k-1) \leqq x \leqq 1$;

$u_k(x) = 1/k$ if $x = 1/2k$;

$u_k(x)$ is defined linearly in the intervals $[1/(2k+1), 1/2k]$, $[1/2k, 1/(2k-1)]$.

The series $\sum_{k=1}^{\infty} u_k(x)$ satisfies the required conditions.

II. *Solution by P. R. Meyer, Hunter College.* Yes. A series $\sum u_k(x)$ such that $u_k'(x)$ approaches zero uniformly may be achieved as follows. We define first $v_1(x)$ by:

$$v_1(0) = v_1(1) = 0, \qquad v_1\left(\frac{1}{2}\right) = \frac{1}{2 \log 2},$$

$v_1(x)$ is linear in $[0, \frac{1}{2}]$ and $[\frac{1}{2}, 1]$. $v_2(x)$ is a roof function on $[0, \frac{1}{2}]$ with maximum height of $1/4 \log 4$ at $x = \frac{1}{4}$, and zero for the rest of $[0, 1]$. $v_3(x)$ is a roof function on $[\frac{1}{2}, 1]$ with maximum height of $1/4 \log 4$ at $x = \frac{3}{4}$. Similarly v_4, v_5, v_6, v_7 are defined as roof functions on $[0, \frac{1}{4}], \cdots, [\frac{3}{4}, 1]$, respectively, with maximum heights of $1/8 \log 8$ at the midpoints of these intervals. We see that

$$\sum \|v_k\| = 1/2 \log 2 + (\tfrac{1}{4} + \tfrac{1}{4})/\log 4 + \cdots = \infty,$$

$$\sum v_k(x) \leqq 1/2 \log 2 + 1/4 \log 4 + 1/8 \log 8 + \cdots < \infty.$$

The $u_k(x)$ are now obtained by applying a simple smoothing operation to v_k.

Also solved by Andreas Blass, R. P. Boas, Béla Bollobás (Hungary), Robert Breusch, T. J. Burke, Yu Chang, P. R. Chernoff, Louis Comtet (France), Stephen Curtis, R. J. Driscoll, John Fridy, Robert Goldstein (England:, G. A. Heuer, D. A. Hejhal, D. W. Hight, M. S. Klamkin, E. S. Langford, D. C. Lewis, Jr., Arthur Lieberman, W. S. Loud, M. D. Mavinkurve (India), Gideon Peyser, Stanton Philipp, Jürg Rätz (Switzerland), Ronald Rietz, J. T. Rosenbaum, W. F. Trench, Bertram Walsh, and the proposer.

NOTE. The second solution above was motivated by the question: Do uniform convergence and some additional condition on u_k imply the applicability of the Weierstrass M-test? We see, of course, from the theorem quoted in the first solution that an example with $\|u_k'(x)\| \to 0$ exists; any conditions on u_k would have to imply finite dimensionality of the resulting space, as noted by Walsh in his solution.

Klamkin refers to the literature for other examples—e.g. E. W. Hobson, *Theory of Functions of a Real Variable* v. II, 1957, p. 119. He also quotes a theorem of Baire to the effect that the Weierstrass M-test will apply to any uniformly convergent series after an appropriate insertion of brackets; this may be easily verified in the examples above.

Convex Hull of a Twisted Cubic

5391 [1966, 547]. *Proposed by J. H. Halton and M. Skibinsky, Brookhaven National Laboratory*

Give an explicit characterization of the convex hull of the arc from $t=0$ to $t=1$ of the twisted cubic $x=t$, $y=t^2$, $z=t^3$.

Solution by the proposers. Let $a_i=(i, i, i)$, $i=0, 1$, and define the truncated cones

$$C_i = \bigcup_{q\in S} \{((1-\theta)a_i + \theta q) : 0 \leqq \theta \leqq 1\}.$$

The convex hull of S is the bounded set which has the boundary $C_0 \cup C_1$. Let $*$ denote the convex hull; then $C_i \subset S^*$ and $S \subset C_i \subset C_i^*$, $i=0, 1$, so that $C_i^* = S^*$, $i=0, 1$.

On the other hand, if we denote by $\hat{C}_i$ the untruncated cone corresponding to C_i, it is easily shown that

$$(\hat{C}_0)^* \cap (\hat{C}_1)^* = \left\{(u, v, w) : 0 \leqq u \leqq 1,\ u^2 \leqq v \leqq u,\ \frac{v^2}{u} \leqq w \leqq v - \frac{(v-u)^2}{1-u}\right\},$$

where left and right hand sides, in the inequality on w inside the brackets, are to be interpreted for $u=0$ and 1, respectively, as the corresponding limits, namely, 0 and 1. But this set is also C_0^* (alternatively, C_1^*) and its boundary is $C_0 \cup C_1$.

NOTE. For generalizations and further interpretations for problems of this nature, John R. Isbell refers us to Memoir no. 12 of the American Mathematical Society, S. Karlin and L. S. Shapley, *Geometry of Moment Spaces.*

A Function of the Base in the Representation of Real Numbers

5392 [1966, 547]. *Proposed by Hwa Hahn, Pennsylvania State University*

Let $f(x)$ be the number obtained from a real x by reading the representation of x in the base p as the representation in the base $q (1 < p \leqq q)$. Evaluate $\int_0^1 f(x)dx$.

Solution by C. R. Mac Cluer, University of Michigan. For each x in $[0, 1]$ let $a_m(x)$ be defined by $x = \sum_{m=1}^{\infty} a_m(x)/p^m$. Then except for some rational values of x, $a_m(x)$ is a well defined periodic, integral valued, measurable, staircase type function, and

$$\int_0^1 a_m(x)dx = \frac{0 + 1 + 2 + \cdots + (p-1)}{p} = \frac{p-1}{2}.$$

But $f(x) = \sum_{m=1}^{\infty} a_m(x)/q^m$. Thus

$$\int_0^1 f(x)dx = \sum_{m=1}^{\infty} \frac{1}{q^m} \int_0^1 a_m(x)dx = \frac{p-1}{2q} \sum_{m=1}^{\infty} \frac{1}{q^m} = \frac{p-1}{2(q-1)}.$$

Also solved by D. W. Bailey, P. T. Bateman, Andreas Blass, J. R. Blum, Robert Breusch P. R. Chernoff, Addison Fischer, G. J. Foschini, R. G. Hart, D. A. Hejhal, G. A. Heuer, E. C. Hook, James Kiefer, M. S. Klamkin, E. S. Langford, D. A. Prener, Ronald Rietz, Alan Saleski, Sidney Spital, W. F. Trench, and the proposer.

The Matrix $a_{ij} = (i, j)$

5393 [1966, 547]. *Proposed by A. A. Mullin, University of California, Livermore*

Does there exist an integer for which the $n \times n$ matrix whose elements are $a_{ij} = (i, j)$ is singular? (i, j) is the greatest common divisor of the natural numbers i and j.

Solution by W. J. Blundon, Memorial University of Newfoundland. Let X_n be the given matrix. Define two $n \times n$ matrices B and C as follows.

$$B = [b_{ij}] \quad \text{where} \quad b_{ij} = \begin{cases} \phi(i) & j = i, \\ 0 & \text{otherwise;} \end{cases}$$

$$C = [c_{ij}] \quad \text{where} \quad c_{ij} = \begin{cases} 1 & j \mid i, \\ 0 & \text{otherwise;} \end{cases}$$

and let C' denote the transpose of C. It follows that $X_n = CBC'$ since the ijth term of this matrix is equal to

$$\sum_{k=1}^{n} c_{ik} b_{kk} c'_{kj} = \sum_{k \mid (i,j)} \phi(k) = (i, j)$$

from the well-known summation of the ϕ-function. Now let $\det C = \det C' = 1$. Thus $D_n = \det X_n = \det B = \phi(1)\phi(2) \cdots \phi(n)$. Since $\det X_n$ is always positive, X_n is never singular.

[Note the recurrence relation: $D_n/D_{n-1} = \phi(n)$.]

Also solved by Eugene Allgower, Anders Bager (Denmark), P. T. Bateman, Andreas Blass, Robert Breusch, E. P. Emerson, N. J. Fine, J. R. Isbell, James Kiefer, E. S. Langford, Andrzej Makowski (Poland), Ka Menehune, C. B. A. Peck, Stanton Philipp, Bob Prielipp, Jürg Rätz (Switzerland), Henry Riccardo, and D. P. Roselle.

NOTES. Bateman, Rätz and Riccardo found the problem in Polya und Szegö, *Aufgaben und Lehrsätze*, V.2, part 8, number 57.

Peck refers to Muir, *Theory of Determinants in the Historical Order of Development*, V.3, pp. 116–121, for generalizations. The first known appearance of this result seems due to H. J. Smith—as noted by Bager and Roselle; see, e.g., Dickson, *History of the Theory of Numbers*, V.1, pp. 122–123.

Makowski refers us to B. Gyires *On a generalization of Smith's determinant theorem*, Publ. Math. Debrecen, 5 (1957–8) 162–171.

Finally, the merits of this problem were recognized previously in this Department, when a generalization appeared as no. 4101 [1945, 165] and was subsequently inserted in the *Otto Dunkel Memorial Problem Book*, this MONTHLY, V. 64 #7, Part 2, p. 35.

An Inequality in the Complex Plane

5394 [1966, 547]. *Proposed by P. J. O'Hara, Jr., University of Miami, Coral Gables, Florida*

Show that the functions, $(1-z)/(1-z^n)$, $n=1, 2, \cdots$, are uniformly bounded in modulus on the disk $\{z: |z-\frac{1}{2}| \leqq \frac{1}{2}\}$ in the complex plane; and that in fact for all n the bound is attained at $z=0$.

I. *Solution by Mary R. Embry, University of North Carolina at Charlotte.* Let $D=\{z: |z-\frac{1}{2}|<\frac{1}{2}\}$ and $C=\{z: |z-\frac{1}{2}|=\frac{1}{2}\}$. Define

$$f_n(z) = \begin{cases} \dfrac{1-z}{1-z^n} & \text{for } z \neq 1, \\ \dfrac{1}{n} & \text{for } z = 1, \end{cases} \qquad n = 1, 2, \cdots.$$

The f_n are analytic on D and continuous on $C \cup D$. For $n=1$, $|f_n(z)| \equiv 1$; for $n>1$, f_n is nonconstant and, with $z \in D$, $|f_n(z)| < \sup(|f_n(z)| : z \in C)$.

If we assume that $\sup(|f_n(z)| : z \in C) > 1$ for some $n>1$, then there exists a z on C, $z \neq 0$, $z \neq 1$ and $|f_n(z)| = 1$. Write $z = re^{i\theta}$ where $r = \cos\theta$. It follows in turn that

$$r^2 - 2r\cos\theta = r^{2n} - 2r^n \cos n\theta,$$
$$1 = 2r^{n-2}\cos n\theta - r^{2n-2}.$$

Since $0<r<1$ and $\cos n\theta \leqq 1$, we have $1 \leqq 2r^{n-2} - r^{2n-2} < 2r^{n-1} - r^{2n-2}$ or $(1-r^{n-1})^2 < 0$. This contradiction implies that $\sup |f_n(z)| \leqq 1$ in $C \cup D$.

II. *Solution by Stanton Philipp, University of California at Riverside.* In Problem 4975 [1962, 927] it is shown that $|z^{n+1}-1| > |z^n||z-1|$ if $\mathrm{Re}(z) \geqq 1$. Replacing z by $1/z$, it follows that $|(1-z)/(1-z^n)| \leqq 1$ if $|z-\frac{1}{2}| \leqq \frac{1}{2}$ and $\mathrm{Re}(1/z) \geqq 1$.

Also solved by P. G. Bugl, Robert Breusch, D. Ž. Djoković (Yugoslavia), James Kiefer, M. S. Klamkin, Al Somayajulu, and the proposer.

Games with a Winning Strategy

5395 [1966, 547], *Proposed by Roy Westwick and W. A. McWorter, University of British Columbia*

Suppose G is a two-person game satisfying:

(1) The players play alternately.

(2) There is no draw.

(3) There are at least one and at most $N(<\infty)$ plays a player can make. Prove that either there is a strategy insuring a win for the first player, or there is a strategy insuring a win for the second player.

I. *Solution by John Lawrence, Eastern Ontario Institute of Technology.* This theorem obviously does not apply to games of chance. If $N=1$, either the first player, A, has a play such that the second player, B, has no counterplay, or he does not. In the former case, A will win by the use of proper strategy, while in the second case, B will win. Thus the theorem is true for $N=1$.

Suppose the theorem is true for $N \leqq M-1$ and suppose that H is a game with $N=M$. After $M-1$ plays there will be some arrangement such that in the next play, A has a move such that B has no counter-play or there will be no such arrangement. Define game H' as follows:

(1) The plays are the same as for H.

(2) A is the winner in H' if a winning arrangement has been achieved in the first $M-1$ plays of H.

(3) B wins if A does not win.

(4) There are at most $M-1$ plays.

From the definition, if A can win H' then he can win H. The same applies to B. Thus there is a strategy insuring a win of H for a given player if there is a strategy insuring a win of H' for that player. The theorem is thus proved by induction.

II. *Solution by Donald Quiring, Las Vegas, Nevada.* Suppose game G satisfies the hypothesis but there does not exist a winning strategy for either player. We first establish that at some stage in the game a situation is reached in which a winning strategy does exist for one of the players. Call the players A and B without regard to who moves first. Suppose the game must end in victory for A after a move by A. Immediately before A made that move he had a simple winning strategy—namely, to make the critical move. If the game must end in victory for A after a move by B, then A has a winning strategy of doing nothing (if this is not properly regarded as a strategy, the solution merely requires rewording).

Now consider the first point in the game at which A was in possession of a winning strategy. If A has just moved, then he clearly had a winning strategy immediately before he made that move. We conclude that B has just moved.

Immediately before B's last move, there was no winning strategy for A. Therefore B must have been able to make a move which would not give A a winning strategy. In other words, a win by A requires a mistake by B, and the

game will never end if neither player makes a mistake. This contradicts the hypothesis and we conclude that the required winning strategy must exist at the outset.

Also solved by R. G. Hart, James Kiefer, D. L. Silverman, and the proposer.

Editorial Note. As was pointed out by Silverman, the key word "play" in hypothesis (3) must be interpreted as "round" and there are to be a finite number of these rounds. The actual number of possibilities in each round may indeed be infinite. Moreover, the solution depends on players seeing opponent's choices. If these conditions are not fulfilled, the result of the problem is not true as seen in counterexamples provided by D. E. Daykin (Malaysia), Scott Guthery, and John R. Isbell.

An Identity for Bessel Functions

5397 [1966, 548]. *Proposed by R. E. Shafer, University of California at Livermore*

Show, for $|\operatorname{Re}(\nu)| < \frac{1}{2}$ and $|\arg z| < \pi$, that

$$K_\nu(z) = e^{-z} z^\nu \cos \pi\nu \int_0^\infty \frac{e^{-t}}{t+z}\, t^{-\nu} I_{-\nu}(t)\, dt,$$

where I_ν, K_ν are modified Bessel functions.

Solution by E. L. Koh, State University of New York at Stony Brook.

From the *Tables of Integral Transforms* by Erdelyi *et al.*, Vol. 2 (McGraw-Hill, 1954), p. 229, eq. 36, we have the Stieltjes transform:

$$\int_0^\infty \frac{t^\nu e^{-t} I_\nu(t)}{t+z}\, dt = \frac{z^\nu e^z K_\nu(z)}{\cos \pi\nu}; \qquad |\operatorname{Re}(\nu)| < \tfrac{1}{2},\ |\arg z| < \pi.$$

This yields

$$K_\nu(z) = e^{-z} z^{-\nu} \cos \pi\nu \int_0^\infty \frac{e^{-t}}{t+z}\, t^\nu I_\nu(t)\, dt.$$

Replacing the order ν by $-\nu$ and noting that $K_\nu(z) = K_{-\nu}(z)$ and $\cos \pi\nu = \cos(-\pi\nu)$ we have the desired result. (Note the correction $I_{-\nu}(t)$ instead of $I_\nu(t)$ as originally printed.)

Also solved by S. P. Singh, and the proposer.

Limit Points of Partial Sums of Rearranged Series

5398 [1966, 548]. *Proposed by G. A. Heuer, Concordia College, Moorhead, Minnesota*

Let $\sum a_n$ be a conditionally convergent series, S the set of its partial sums, and S' the derived set (set of accumulation points) of S. As is well known, rearranging the series $\sum a_n$ may alter S'. Consider all possible arrangements of the fixed series $\sum a_n$. What are the sets S' which occur?

Solution by Hugh Noland, University of California at Davis. Let $\sum a_{k(n)}$ be a rearrangement of the conditionally convergent series $\sum a_n$, and let α and β

be real numbers (extended) which are accumulation points of the set of partial sums of $\sum a_{k(n)}$. Since $\lim_{n\to\infty} a_{k(n)} = 0$, it is clear that every real number between α and β is also an accumulation point of the above-mentioned set.

Thus, using Riemann's theorem, the sets S' (in the notation of the problem) consist of all closed intervals (including singleton sets) of the extended real line.

Also solved by Béla Bollobás (Hungary), D. E. Daykin (Malaysia), D. A. Hejhal, L. R. King, M. S. Klamkin, M. D. Mavinkurve (India), Sidney Spital, Yu Chang, and the proposer.

Klamkin offers the following addendum for complex series. The "range of summation" of a series Σa_n of complex terms, i.e., the set of values which may be obtained as sums of convergent rearrangements of Σa_n, is either a definite point, or a definite straight line, or the entire plane. Other cases cannot occur. A proof is given by P. Levy (Nouv. Annales (4), Vol. 5 (1905), p. 506), but an unexceptional statement of the proof is not found earlier than in E. Steinitz (*Bedingt konvergente Reihen und konvexe Systeme*, J. Reine Angew. Math., Vol. 143, 1913; Vol. 144, 1914; Vol. 146, 1915. The case that is still open is: what is the set of accumulation points when the deranged sums in the complex case lie on a definite straight line?

Spectral Radius of (0, 1) Matrices

5399 [1966, 548]. *Proposed by L. F. Shampine, Sandia Corporation, Albuquerque, N. M.*

Let $p(n)$ be the largest spectral radius attained by any (0, 1) matrix with n nonzero entries. Prove $p \sim \sqrt{n}$.

Solution by R. A. Brualdi, University of Wisconsin. If $A = [a_{ij}]$ is any (0, 1) matrix with n 1's and $\lambda_1, \cdots, \lambda_m$ are the eigenvalues of A, then by Schur's inequality,

$$\sum_{i=1}^{m} |\lambda_i|^2 \leqq \sum_{i,j=1}^{m} a_{ij}^2,$$

we see that $\max_{1\leqq i\leqq m} |\lambda_i| \leqq \sqrt{n}$. Thus $p(n) \leqq \sqrt{n}$. Let k be the unique positive integer such that $k^2 \leqq n < (k+1)^2$. Then the matrix

$$\begin{bmatrix} J_k & 0 \\ 0 & I_{n-k^2} \end{bmatrix},$$

where J_k is the $k \times k$ matrix of all 1's and I_{n-k^2} is the identity matrix of order $n-k^2$, is a (0, 1) matrix having n 1's and with maximal characteristic root equal to k. Hence $p(n) \geqq k$. But then

$$\frac{k}{k+1} \leqq \frac{p(n)}{\sqrt{n}} \leqq 1.$$

Since as $n \to \infty$, $k \to \infty$ and thus $k/(k+1) \to 1$, we have the desired result

$$\lim_{n\to\infty} \frac{p(n)}{\sqrt{n}} = 1.$$

Also solved by R. Dormaty (Austria), P. J. Nikolai, J. T. Rosenbaum, and the proposer.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto 5, Canada. Correspondence about Reviews will be welcome.

Notes on Differential Geometry. By Noel J. Hicks. Van Nostrand, Princeton, N. J., 1965. vi+183 pp. $2.95.

This fine book is the third in a series of mathematical studies published in paperback form by Van Nostrand. The topics discussed include the main results from classical differential geometry, given a fresh look, and some results, such as the Weil homomorphism, which have not appeared before in an introductory text. Both the language and the techniques used are modern.

The contents by chapter are: 1. Manifolds. 2. Hypersurfaces of R^n. 3. Surfaces in R^3. 4. Tensors and Forms. 5. Connexions. 6. Riemannian Manifolds and Submanifolds. 7. Operators on Forms and Integration. 8. Gauss-Bonnet Theory and Rigidity. 9. Existence Theory. 10. Topics in Riemannian Geometry.

The treatment is quite brisk. Chapters 4 and 7, in particular, are almost too brief. The one hundred problems in the text are crucial to the development. The book has an extensive bibliography and is well documented, but is marred by many typographical errors and misspelled names.

This book is highly recommended to anyone who wants an introduction to modern differential geometry or a modern treatment of results from classical geometry. Prerequisites for the book are linear algebra, advanced calculus or elements of real analysis including some calculus of vector functions and the basic existence theorems in ordinary differential equations. It can be used for courses at either the undergraduate or graduate level and should be useful to those graduate students who are preparing for qualifying exams in the area. At $2.95, it is a very good buy.

G. F. FEEMAN, Williams College

Mathematical Discourses: The Heart of Mathematical Science. By Carroll V. Newsom. Prentice-Hall, Englewood Cliffs, N. J., 1963. 121 pp. $5.50.

Euclidean geometry consists of a set of primary propositions, which are unproved postulates, a set of secondary propositions, which are logical consequences of the primary propositions, and a set of terms, some of which are necessarily undefined. These propositions and terms constitute what is known as a mathematical discourse, and this is what this book is about. There are many kinds of mathematical discourses mentioned and some are discussed in detail. There are discourses for various types of non-Euclidean geometry, for projective geometry, for various algebras, for Newtonian mechanics, and so on.

In general the historical approach is used, and after an interesting chapter on how man began to be mathematical the author introduces Euclid's list of ten primary propositions. These are criticized and then replaced by Robinson's (1940) list. Since the secondary propositions are logically included in the primary propositions, although this is often not immediately obvious, it would appear that in the last analysis mathematics is an argument in a vacuum. The author notes that Aristotle recognized this, and also quotes a number of modern authors, some of whom assert that this is true not only of mathematical science but of other sciences as well. "Formal sciences are characterized by the fact that the theorems are not 'about' some phase of the existing world but are 'about' what is *postulated* by thought" (Nagel 1939). Mathematics is "a game played on paper with meaningless symbols" (D. Hilbert 1862–1943). "Mathematics may be defined as the subject in which we never know what we are talking about, nor whether what we are saying is true" (B. Russell 1901), but mathematics is not the only subject of this sort.

Mathematical science becomes as we say useful as one intuitively believes that certain observed phenomena satisfy very closely the conditions imposed in the discourse. This is called an interpretation of the discourse, and the discourse may have been expounded initially without any interpretation having been thought of. For example there is a geometry due to Riemann which was without interpretation until it was used in general relativity theory, which in turn is another mathematical discourse, and which again becomes useful if one believes certain natural phenomena satisfy its conditions. On the other hand quite frequently there may be an interpretation desired and then the discourse invented. The theory of quaternions is mentioned as an example of this.

With the author's rich use of historical material he has made his account absorbingly interesting and his carefully phrased sentences have made it easily understandable by the nonprofessional mathematicians for whom the book was written, not of course by all nonmathematicians, but surely by those with a high school education, a philosophic temper and a willingness to make a minor mental effort. In the preface it is stated that "an understanding of the subject of this book is essential to mathematical literacy." This may be putting it a bit strong. There have been many literate mathematicians who have been interested not in the foundations of mathematics but in the superstructure, but the book is certainly necessary to an understanding of the philosophy of mathematics and of the significance of much modern work. It would seem that many college students will find it both interesting and stimulating.

B. H. CAMP, Wesleyan University

Non-Standard Analysis. By A. Robinson. Edited by L. E. J. Brouwer, A. Heyting, A. Robinson and P. Suppes. North Holland, Amsterdam, 1966. xi+293 pp. $10.00. (Teleg. Rev. March 1967.)

Aristotle held that in mathematics, as in nature, nothing actually is infinitely large or infinitely small. A potentiality for indefinite increase or decrease in magnitude was all that was permitted in peripatetic philosophy or in classical mathematics based on the axioms of Eudoxus and Archimedes. The differentials of Leibnizian calculus seemed to point to the possibility of infinitely small magnitudes, but this notion lost support with the rise of the limit concept of D'Alembert, Cauchy, and Weierstrass. The infinitely large, by contrast, achieved canonical status in mathematics through Cantor's *Mengenlehre.* The history of mathematics shows, however, that no advance continues indefinitely in a given direction, nor is any achievement established beyond question. Consequently it should occasion no surprise that the book under review presents a closely-reasoned elaboration of the non-conforming thesis that "the infinitely small and infinitely large numbers of a non-standard model of Analysis are neither more nor less real than, for example, the standard irrational numbers."

The volume is the outcome of a view developed by the author in seminars and papers since 1960, inspired in part by Skolem's non-standard models of arithmetic. It purports to demonstrate "that the concepts and methods of contemporary Mathematical Logic are capable of providing a suitable framework for the development of the Differential and Integral Calculus by means of infinitely small and infinitely large numbers." Following substantial sections on such themes as general topology, functions of real and complex variables, linear spaces, and groups, the book closes with a chapter "Concerning the History of the Calculus" which effectively summarizes developments from Leibniz to 1961. More than a third of this well-written chapter is devoted to an analysis of the concepts and language of Cauchy, the intention being to show that these are not so far removed from the non-standard approach as usually is supposed. Admitting that Cauchy's differentials were, at least in the earlier stage, variables rather than numbers, Robinson argues that subsequent definitions by Cauchy can readily be interpreted in the sense of non-standard analysis. Such interpretation appears to be somewhat tendentious, but one

can readily subscribe to the author's conclusion that "Cauchy stands in the history of the calculus not as a man who broke with tradition and swept away old and rotten foundations to make room for new and sound ones but rather as a link between the past and the future." Whether the future will belong to the customary Weierstrassian view or to the unwonted approach of non-standard analysis—or to both—only time can tell. In any case, the present book will warrant attention from mathematicians for its provocative thesis and from historians for the *prêcis* in the final chapter.

C. B. BOYER, Brooklyn College

Probability Theory. By K. Krickeberg. Addison-Wesley, Reading, Mass., 1965. x+230 pp. $8.95.

The book under review is an English translation of the original German edition, titled *Wahrscheinlichkeitstheorie*, published by Teubner, Stuttgart, 1963. The author states that this book is suitable for an advanced undergraduate or first-year graduate course in probability. The only prerequisites specified are calculus and the elementary theory of real finite-dimensional linear spaces, as some measure-theoretic concepts are introduced and used throughout the book. Chapter titles: I. Random variables, II. Expectations and distributions, III. Sequences of independent random variables, IV. Conditional expectations, V. The Brownian motion and the Poisson process.

The chapter titles listed above give some indication of the general scope of this book; and, in general, we feel that this book is a very well written, mathematically rigorous introduction to probability theory. Our only somewhat negative comment concerns the suitability of this volume as an introductory text for senior and first-year graduate students at universities in the United States. In many universities, graduate students specializing in probability are encouraged to have a more comprehensive knowledge of both measure theory and probability than that which could be obtained from this book; hence the book would not, in general, be suitable for this group of students. It does, however, appear to be an ideal text for (1) mature seniors, (2) graduate students with a background in measure theory, or (3) the more mathematically oriented graduate students in the sciences and engineering, who want a modern and mathematically sound introduction to probability theory.

A. T. BHARUCHA-REID, Wayne State University

Elements of the theory of functions. Vol. 90. By R. S. Guter, L. D. Kudryavtsef and B. N. Levitan. Translated by H. F. Cleaves. Pergamon, Oxford, 1966. xii+215 pp. $8.50. (Teleg. Rev. January 1967.)

The intent of the Russian edition of this book was to present to the nonexpert some of the basic definitions and results in the theory of functions of a real variable, approximation and interpolation of functions, and the theory of almost periodic functions.

In carrying out such a purpose it is necessary that special care be taken to be precise and correct since there are relatively few internal checks on the material.

I have not seen the Russian original but this translation is bad. It appears to have been done by a nonmathematician and appears never to have been proof-read. A catalog of the errors in translation, garbled text, odd terminology, bad punctuation, typographical errors, and just plain bad English would take many pages.

A few random samples may suffice to indicate what is meant in the preceding paragraph. On p. 66 the word *complement* is used when *completion* is meant, on p. 83 the *inequality of the triangle* is referred to, on p. 81 a function which is zero almost everywhere is said to be "equivalent to identical zero," on p. 173 a function which is different from zero *at most* on a denumerable set is said to "differ from zero *very considerably* on a denumerable set."

There are symbols missing, inequalities reversed, continual confusion between the use of the definite and indefinite articles, words like *lower* translated into their antonyms etc., etc.

Finally, as if the above were not enough, the book is badly cross indexed and the bibliography fails to mention the availability in English of several titles given in Russian.

I cannot recommend the book to anyone.

J. B. ROBERTS, University College Dar Es Salaam and Reed College

Theory of Probability. By Bernard Harris. Addison Wesley, Reading, Mass., 1966. ix +294 pp. $9.75. (Teleg. Rev. March 1967.)

This is a closely-written, businesslike account of the mathematical aspects of probability theory, starting from scratch with the Kolmogorov axioms, covering combinatorial probabilities, random variables on discrete and continuous sample spaces, characteristic functions, a certain amount of distribution theory and a selection from the more important limit theorems of probability theory. The one chapter devoted to random experiments is so compressed and abbreviated that it could have been left out without appreciable loss.

Through the continued use of distribution functions and the Riemann-Stieltjes integral, the author is able to cover in a connected and complete fashion a substantial core of probability theory in a brief 250 pages. I think a treatment of this sort is bound to seem a bit dull to a beginner, but the large collection of quite superior problems gives life to the book as a whole.

Presumably the book was written as a textbook to accompany a lecture course to students with some mathematical attainments, at least to the level of advanced calculus. It should serve this purpose well. It is a fairly complete skeleton, well wired together, leaving to the lecturer the task of putting flesh and perhaps some other adornments on the bones. This, to my way of thinking, is what a textbook should do.

D. B. DE LURY, University of Toronto

A Treasury of Mathematics. A collection of source materials, edited with biographical and historical sketches by Henrietta O. Midonick, Philosophical Library, New York, 1965. xxiv+820 pp. $15.00.

One of the constant needs of anyone interested in the history of mathematics is having good source materials. This collection includes 54 selections, 11 Chinese, 10 Greek, 9 English, 5 German, 4 Indian, 2 Hebrew, 2 Arabian, 2 French, 2 Egyptian, 2 American, and one each of Babylonian, Mayan, Incan, Danish and Flemish.

It is unfortunate that the book is arranged alphabetically by author, rather than by natural groupings, such as subject or period. The few modern selections could just as well be transferred to a separate volume devoted to the mathematics of the post-Renaissance period, and replaced by selections from authors who have been omitted, such as al-Kashi and Leonardo of Pisa. The bias toward Chinese mathematical texts is overextended but understandable, considering the relative neglect of Chinese contributions to mathematics in ancient and medieval times.

This is a book which belongs in all mathematic libraries, even at the inflated price.

CHARLES ARONSON, Berkeley, California

Mathematics in the Social Sciences and Other Essays. By Richard Stone. M.I.T. Press, Cambridge, Mass. 1966. xiii+291 pp. $12.00.

Professor Stone of Cambridge University is perhaps today the most outstanding econometrician in England. This collection of essays published in various journals 1960–64 should also be of interest to mathematicians, who concern themselves with the more advanced applications of mathematics in the social sciences.

We now list the essays and indicate the mathematical methods used: 1. Mathematics

in the social sciences. 2. The *a priori* and the empirical in economics (matrices). 3. The housekeeper and the steersman (cybernetics). 4. Misery and bliss (calculus). 5. Three models of economic growth (calculus of variations). 6. Models of the national economy for planning purposes. 7. A demonstration model for economic growth (matrices). 8. Transitional planning (difference equations). 9. A model of the educational system (difference equations). 10. Social accounts at the regional level: a survey (matrices). 11. A comparison of the economic structure of regions based on the concept of "distance" (multivariate methods of statistics). 12. Population mathematics, demand analysis and investment planning (Markov chains). 13. A dynamic model of demand (difference equations). 14. The changing pattern of consumption (matrices, least squares). 15. Private savings in Britain, past, present and future (difference equations, statistical estimation). 16. Multiple classifications in social accounting (matrices). 17. British economic balances in 1970: a trial run on rocket (matrices, difference equations).

GERHARD TINTNER, University of Southern California

Topological Structures. By Wolfgang J. Thron. Holt, Rinehart and Winston, New York, 1966. ix+231 pp. $9.50.

This book is designed as a text for a full-year course on general topology at the senior or first-year graduate level. The standard material for such a course is well covered, except for the topic on topology of function spaces. Thus neither the Stone-Weierstrass Theorem nor Ascoli's Theorem are presented. A special feature of the book is a chapter devoted to a thorough account of the proximity spaces. There is also a chapter on topological groups. Both filters and nets are used. The use of filters in this book is more frequent than in other texts on general topology in the English language.

The author gives a good deal of attention to the historical development of the basic ideas. The exposition is well motivated by numerous historical remarks and intuitive observations. The book is divided into 23 short chapters, with exercises provided at the end of each chapter.

KY FAN, University of California, Santa Barbara

Brief Numerical Methods. By Wendell E. Grove. Prentice-Hall, Englewood Cliffs, N.J., 1966. xi+117 pp. $6.75.

This book is a very lucid introduction to numerical methods. It presents computer-oriented techniques for solving a relatively broad scope of problems.

Topics included in the text are: a rather exhaustive treatment of the solution of algebraic and transcendental equations by iteration (some simplified flow diagrams are shown); methods for calculating complex roots of equations; the solution of simultaneous equations; the least-squares fitting of curves (including the use of orthogonal polynomials); numerical integration; and the solution of ordinary differential equations. A technique is given for solving an ordinary differential equation with boundary values given at both ends of an interval, and a chapter, dedicated to interpolation techniques, introduces the E and Δ operators. The book presents many less well-known methods which are suitable for machine coding (Wegstein's methods for simultaneous equations, Lin's method for complex roots, Adams-Bashforth and Nystrom methods for solution of differential equations). It gives helpful tips as to the limitations of the techniques. There is only a modicum of misprints in the text (e.g., pp. 44 and 76).

J. C. ROGERS, Omnimetrics

Combinatorial Group Theory. By Wilhelm Magnus, Abraham Karrass and Donald Solitar. Interscience, New York, 1966. x+444 pp. $15.00.

One of the subtleties which the beginning student of group theory has to master is this: When a group is given by generators and defining relations, there is no obvious way

of telling when different expressions represent the same element (even the elements represented by different generators need not be distinct). This is essentially the word problem and from the work of Novikov, Boone and Britton we know that groups with unsolvable word problem exist. But from the point of view of the working group theorist, and even more, of the general mathematician using groups, it is more important to have a good knowledge of methods of solving the word problem. The book under review is devoted to a study of such methods.

The main topics (after a brief review of the basic concepts) are: The presentation of subgroups (Reidemeister-Schreier method) and the Schreier Subgroup Theorem. This leads on to Nielsen transformations, which are applied to automorphisms of free groups, and to knot and braid groups. Free products (also with an amalgamated subgroup) are defined in terms of presentations of the factors and are studied by standard cancellation methods. The theory is developed far enough to yield the Kurosh Subgroup Theorem (but not Grushko's Theorem,which is stated without proof); other applications include the independence theorem and the word problem for groups with one defining relation. A chapter on commutator calculus establishes the connection between groups and Lie rings, proves the existence of basic commutators in the free case and applies the result to study the lower central series, especially for free groups. The final chapter reports (without proofs) on recent results.

Throughout the book the emphasis is on techniques, rather than general results and this outlook is supported by the very substantial collection of exercises, many of interest in their own right. The tone is elementary throughout; the authors are at pains to make themselves understood and at no point do they presuppose any specific knowledge. Of course to profit from the book the reader should have some acquaintance with group theory as well as a liking for combinatorial methods. Given these prerequisites (as well as pencil, paper and patience), the reader will acquire a valuable tool for handling groups, and a most useful collection of specimens.

No doubt the series book has come to stay, but the publishers should desist from putting a book in *two* series: this book is described as vol. 13 of a series of Texts and Monographs, and also as vol. 20 of the Interscience Tracts (of which vol. 13 is Nagata's Local Rings), a most confusing situation which should not be perpetuated.

P. M. COHN, University of London

TELEGRAPHIC REVIEWS

The following abbreviations indicate suggested uses: T (textbook), S (supplementary student reading), P (professional reading for the teacher), TT (Teacher Training), L (Library purchase), 15 (junior level)—18 (second graduate year).

Sêminaire Bourbaki. December 1948–May 1965. Benjamin, New York, 1966. Twelve volumes of from 200–350 pp. $15.00 per vol., $150 for the set. Facsimile (photo-offset) reproduction copied directly from the second mimeographed edition in seventeen volumes of the original notes of 294 lectures, almost entirely in French. Each volume contains a table of contents and an index of authors cited in all twelve volumes. The last has also an alphabetical index of lecturers. An additional volume is planned annually. Libraries should purchase at this high price per page only if they seek completeness. Virtually all the content has appeared or will appear elsewhere. (For a contrary view see *Science* 16 Dec. 1966, p. 1440.)

Guidebook to Departments in the Mathematical Sciences in the United States and Canada. Edited by Raoul Hailpern. The Committee on Advisement and Personnel, Mathematical Association of America, Buffalo, 2nd ed., 1966. 80 pp. 50¢. An invaluable

reference for those who are selecting a place to do undergraduate or graduate work in mathematics. P, L.

German-English Mathematical Vocabulary, 2nd ed. By Sheila Macintyre and Edith Witte. Wiley, New York, 1966. ix+95 pp. $2.95.

NOTE: We are informed by Chelsea Publishing Co., that a new edition of *Commutative Normed Rings* by Gelfand, Raikov, and Shilov will appear this summer "incorporating new material especially written for this edition by Professor Shilov, and eliminating the offending theorem and erroneous proof" mentioned in the review by Gelbaum in this Monthly of February 1967.

Computers and Computing

Introduction to Cybernetics. By Viktor M. Glushkov. Translated by Scripta Technica. Academic Press, New York, 1966. x+322 pp. $11.75. Abstract theory of algorithms, Boolean functions, automata, self-organizing systems, electronic digital computers and programming, the predicate calculus and the automation of the processes of scientific discovery. P, L.

Analysis of Numerical Methods. By Eugene Isaacson and Herbert Bishop Keller. Wiley, New York, 1966. xv+541 pp. $11.95. ". . . we stress techniques for the development of new methods. This requires knowing why a particular method is effective on some problems but not others. Hence we are led to the analysis of numerical methods rather than merely their description and listing." Linear systems, matrix inversion, nonlinear equations, eigenvalues, polynomial approximation, differences, integration, ordinary and partial differential equations. (Reviewed in *Science* 24, February 1967.) T (15–16) P, L.

Logic and Algorithms. With Applications to the Computer and Information Sciences. By Robert R. Korfhage. Wiley, New York, 1966. xii+194 pp. $7.95. ". . . evolved from the basic logic course for students in mathematics and the computer sciences . . . and a similar but more elementary course presented to an industrial group of computer users . . . logic books might be grouped into three main categories: those written by philosophers . . . the mathematical logic books . . . and the books written for engineers. . . . This book is written on the premise that computer users and designers need to have some knowledge of all three aspects of logic as well as the fundamentals of algorithm theory." Set algebras, relations, mappings, Boolean algebras, propositional calculus, quantification theory, internal symbol representations of a binary vector, formal languages, history. T (14–15), S, P.

Programming Real-Time Computer System. By James T. Martin. Prentice-Hall, Englewood Cliffs, N. J., 1965. xii+386 pp. $12.00. This book discusses the design, programming, testing and implementation of "real time" computer systems, paying special attention to management problems. P.

Interval Analysis. By Ramon E. Moore. Prentice-Hall, Englewood Cliffs, N. J., 1966. xi+145 pp. $9.00. ". . . addressed to the mathematician, the numerical analyst, and the programmer. The title refers to a set of concepts and techniques based on treating an *interval* of real numbers as a new kind of number, represented by a pair of real numbers, namely, its left and right endpoints. The techniques can be programmed for computers in order to obtain simultaneously upper and lower bounds to exact solutions of equations of various types . . . a number of interesting and challenging research problems concerned with ways in which the methods and programs can be

extended, refined, and improved. The material in this book was presented as a graduate course in the Computer Sciences Department of the University of Wisconsin . . ." T (17), S, P.

Theory of Self-Reproducing Automata. By John von Neumann, edited and completed by Arthur W. Burks. University of Illinois Press, Urbana, 1966. xix+388 pp. $10.00. Part I: "Theory and Organization of Complicated Automata," five lectures at the University of Illinois in 1949 (pp. 31–87). Part II: The Theory of Automata (pp. 91–380). Both are carefully edited from manuscripts left at von Neumann's untimely death, and they are introduced by a 28 page analysis of all von Neumann's work on computers and automata. As the editor points out, the unfinished nature of the manuscripts allows us "to see von Neumann's powerful mind at work." Clearly this is an important mathematical and historical document, a must for anyone interested in computers, automata or cybernetics. P, L.

PL/IProgramming Primer. By Gerald M. Weinberg. McGraw-Hill, New York, 1966. ix+278 pp. $5.95. ". . . a text for an introductory course in computer programming . . . also as an introduction to PL/I . . . one of the first higher level languages which shows promise of being reasonably universal in its application, at least for the applications that exist today . . . " T, S, P.

A Short Introduction to Numerical Analysis. By M. V. Wilkes. Cambridge University Press, 1966. 76 pp. $4.25. Elementary treatment of iteration, interpolation, numerical integration and differential equations, simultaneous equations, linear systems. T (14–15), S.

Tables and Formulae for the Spherical Functions $P^m_{-\frac{1}{2}+ir}(z)$. By M. I. Zhurina and L. N. Karmazina. Translated by E. L. Albasiny. Pergamon, New York, 1966. vii+107 pp. $3.50. Forty pages on properties of the functions, seven describing the tables. L.

Mathematical Education

The Role of Axiomatics and Problem Solving in Mathematics. Edited by E. G. Begle for the Conference Board of the Mathematical Sciences. Ginn and Co., Boston, 1966. v+137 pp. $1.60 (paper). A collection of essays solicited by the CBMS at the request of the United States Commission of the International Commission on Mathematical Instruction.

Preface. E. G. Begle. The Use of the Axiomatic Method in Teaching High School Mathematics. F. B. Allen. Lyons Township High School. Western Springs, Illinois. The Use and Abuse of the Axiomatic Method in High School Teaching. A. A. Blank. New York University. The Role of a Naive Axiomatics. R. C. Buck. University of Wisconsin. Mathematics: Its Structure, Logic, and Method. Irving Allen Dodes. Kingsborough Community College of the City University of New York. Axioms, Postulates, and the Teaching of Elementary Mathematics. A. M. Gleason. Harvard University. The Axiomatic Method in Mathematics Courses at the Secondary Level. Leon Henkin. University of California, Berkeley. Mathematics and Axiomatics, Morris Kline, New York University. The Axiomatic Method and School Mathematics. M. E. Shanks. Purdue University. The Axiomatic Method in High School Mathematics. Patrick Suppes. Stanford University. A Use of the Axiomatic Method in Teaching Algebra. H. E. Vaughan. University of Illinois. The Role of Postulates in School Mathematics. G. S. Young. Tulane University.

The Role of Problems in Mathematical Education. R. P. Dilworth, California Institute of Technology. Some Thoughts on Problem Solving. N. J. Fine. Pennsylvania State University. The Role of Problems in the Development of Mathematical

Activity. F. D. Jacobson, Albertus Magnus College. The Role of Problems in Secondary School Mathematics. P. S. Jones. University of Michigan. The Role of Problems in the High School Mathematics Curriculum. P. D. Lax. New York University. On Individual Exploration in Mathematics Education. H. O. Pollak. Bell Telephone Laboratories. On Teaching Problem Solving. George Polya, Stanford University. Problem Making and Problem Solving. P. C. Rosenbloom. Columbia University. Problems in the Teaching of Mathematics. František Wolf. University of California, Berkeley.

Obviously this is a must for everyone interested in mathematical education. Instead of soliciting a review, we invite readers to comment. S, P. L.

Mathematics and the Elementary Teacher. By Richard W. Copeland. Saunders, Philadelphia, 1966. xvii+355 pp. $6.50. Part I: Arithmetic. Part II: Geometry. A reviewer to whom this book was sent writes that its objectives are commendable, but that its use should be discouraged because of much unsound material and a confusing effort to mix modern ideas with "the imprecise, fragmented and mechanistic approaches" of the past.

Algèbre linéaire et géométrie élémentaire. By Jean Dieudonné. Hermann, Paris, 1964. 223 pp. 36 F. An interesting, contentious book on secondary education by a close collaborator of N. Bourbaki. Euclidean geometry appears as an interpretation of linear algebra. The introduction ends as follows: ". . . I have not the slightest personal interest in these matters of secondary education, and I care little if, when or how there is a reform at this level. I have simply wished to place on file for the future historian an example of what one might do in this matter if one tried to act in a *rational* way." (Editor's free translation.) S, P.

Introduction to Contemporary Mathematics. By Sze Tsen Hu. Holden-Day, San Francisco, 1966. viii+202 pp. $7.95 in U.S.A. ". . . for the first fundamental course for mathematical majors after two years of calculus . . . a guided tour . . . emphasizing the austere aspect of abstraction and precision without . . . deeper results . . . calculus isn't necessary." T (13–15) S.

The Number Systems and Operations of Arithmetic. By Orval M. Klose. Pergamon Press, Oxford, London, 1966. xi+265 pp. $3.95. ". . . for the single purpose of explaining to elementary school teachers (both in-service and in-training) the nature of those basic principles of mathematics which form the foundations and structural framework of arithmetic, and how the familiar formal algorithms . . . stem from these principles . . . frankly intuitive approach . . . " TT.

The Study of Arithmetic. By L. Clark Lay. Macmillan, New York, 1966. xv+590 pp. $8.00. TT (year course for future elementary teachers).

Report of the International Clearinghouse on Science and Mathematics Curricular Developments. Compiled under the Direction of J. David Lockard. A joint project of the American Association for the Advancement of Science and the Science Teaching Center, 1966. 291 pp. Free from the Science Teaching Center, University of Maryland, College Park, Md. 20740. The first of an annual series from the International Clearinghouse on Science and Mathematics Curricular Developments, this volume describes current projects in the U.S.A. and 28 other countries. P, L.

Prelude to Analysis. By Paul C. Rosenbloom and Seymour Schuster. Prentice-Hall, Englewood Cliffs, N.J., 1966. 473 pp. $8.25. Not just another precalculus book. It

deals with the prerequisites of a strong calculus course (real numbers, algebraic structures, coordinates, functions, vector algebra, approximation, sequences, induction) in a modern spirit (abstraction and rigor, motivated and related to applications) without the trappings of "modern" mathematics (excessive preoccupation with terminology, logic, set theory, and unmotivated formalism). T (13), S, P, L.

A Path to Modern Mathematics. By W. W. Sawyer. Penguin books, Baltimore, 1966. 223 pp. $1.25 (paper). Written for secondary teachers. Largely on concepts from linear algebra leading to a final chapter on "metric and Banach Spaces." S, TT.

Trends in Elementary School Mathematics. By Lloyd Scott. Rand McNally, Chicago, 1966. ix+215 pp. $3.50 (paper). "This book was written out of empathy for teachers of elementary school mathematics. . . . The expressed need was for an overview of the modern elementary school mathematics program with particular attention to the practical interest of teachers." S, TT, P, L.

History

The Role of Mathematics in the Rise of Science. By Salomon Bochner. Princeton Univ. Press, Princeton, N.J., 1966. x+386 pp. $9.00. Rather philosophical essays written 1961–1965 and accompanied by comments and 150 brief biographies of mathematicians and others. P, L.

Mind and Cosmos. Essays in Contemporary Science and Philosophy. Edited by Robert G. Colodny. Univ. of Pittsburgh Press, Pittsburgh, 1966. xviii+362 pp. $8.00. The third in a series published under the auspices of the Center for the Philosophy of Science at the University of Pittsburgh, this volume contains essays by Herbert Simon (thinking by computers, discovery and problem solving), D. Shapere (Meaning and scientific change), S. Bromberger ("Why-Questions"), C. G. Hempel (induction), W. C. Salmon (inference), J. T. Clark (physics, components of intellectual culture), T. Gold (cosmic processes, time), H. Margenau (quantum theory). S, P, L.

Research Papers in Statistics. Edited by F. N. David and Evelyn Fix. Wiley, New York, 1966. viii+468 pp. $19.30. A volume of research and review papers in honor of Neyman's 70th birthday, including "The Neyman-Pearson Story: 1926–34." By E. S. Pearson. (See review by Wolfowitz in *Science* 20, Jan. 1967.) P, L.

Collected papers of G. H. Hardy. By G. H. Hardy including joint papers with J. E. Littlewood and others. Edited by a committee appointed by the London Mathematical Society. Vol. I. Oxford Univ. Press, London, 1966. 700 pp. $16.80. This first of seven planned volumes contains papers on Diophantine approximation and additive number theory (combinatory analysis and sums of squares, Waring's problem, Goldbach's problem, Inaugural Lecture) with introductory comments to each group of papers, the obituary by Titchmarsh, a table showing the arrangement of papers in all seven volumes, and a complete bibliography of Hardy's papers beginning with a question to the Educational Times in 1899 and ending with a note on Fourier series in 1949. There is a superb informal photograph of Hardy peering over his glasses at the reader. P, L, B.

The Birth of Mathematics in the age of Plato. By Francois Lasserre. World, New York, 1964. 191 pp. $1.65 (paper). Based on analysis of surviving classic texts without, reference to historical studies of van der Waerden, Neugebauer, etc. P.

Measure and the Integral. By Henri Lebesgue. Edited with a biographical essay by

Kenneth O. May. Holden Day, San Francisco, 1966. xii+194 pp. $6.95. Part I: Measure of Magnitudes (*La Mesure des Magnitudes*, 1931–1935), Part II: The development of the Integral Concept (*Sur le développement de la notion d'intégrale*, 1926). Selected bibliography on Lebesgue. S, P, L.

The Algebra of Abu Kamil. By Martin Levey with foreword by Marshall Clagett. Hebrew text, with English translation and commentary with special reference to the Arabic text. Univ. of Wisconsin Press, Madison, 1966. xi+226 pp. $10.00. This earliest (ca. 850–930 A.D.) Arabic algebra after Al-Khwarizmi known to be extant has survived best in this fifteenth century Hebrew version. S, P, L.

The Collected Mathematical Works of J. H. and A. G. M. Michell. Edited by F. W. Niedenfuhr and J. R. M. Radok. Foreword by T. M. Cherry, Noordhoff, Groningen-Holland, 1965. 338 pp. $7.10. Papers in applied mathematics and mechanical engineering by the Australian brothers, J. H. Michell (1863–1940) and A. G. M. Michell (1870–1959). P, L.

De Proportionibus proportionum and Ad pauca respicientes. By Nicole Oresme. Translated and edited by Edward Grant. Univ. of Wisconsin Press, Madison, 1966. xxii+466 pp. $10.75. The first scholarly edition and translation of treatises on proportions and exponents and on the kinematics of circular motion. The original Latin and English translations are on facing pages. "All the tortuous turns and complexities of the text are unraveled and explained . . . and an introduction examines Oresme's career and discusses the meaning and significance of the treatises in the context of medieval mathematics." Well reviewed by Curtis Wilson in *Science* 23, December 1966. P, L.

Logic and Reality in Leibniz's Metaphysics. By G. H. R. Parkinson. Oxford Univ. Press, Oxford, 1965. 159 pp. $5.60. P.

The Mathematical Practitioners of Hanoverian England. 1714–1840. By E. G. R. Taylor. Cambridge Univ. Press, New York, 1966. xv+502 pp. $16.50. This is a sequel to the author's *Mathematical Practitioners of Tudor and Stuart England* (Cambridge University Press, 1954: soon to be reprinted). In spite of some weaknesses (see the review by D. T. Whiteside in *Science*, 30, September 1966), this is an important and useful historical reference. P, L.

Papers presented to J. E. Littlewood on his eightieth birthday. Edited by J. D. Weston. Oxford Univ. Press, New York, 1966. 314 pp. $12.80. A collection of 26 research papers contributed by friends and colleagues. P.

Number Theory

Number Theory. By Z. I. Borevich and I. R. Shafarevich. Translated by Newcomb Greenleaf for Scripta Technica. Academic Press, New York, 1966. x+435 pp. $12.95. ". . . we start from concrete problems . . . General theories arise as tools for solving these . . . these theories are developed . . . so that the reader can see . . . their strength and beauty, and so that he learns to apply them." Congruences, representation by decomposable forms, divisibility, local methods, analytic methods, algebraic supplement. T (15–17), S, P, L.

Theory of the Linear Diophantine Equation. By P. Laborde. Published by the author, Univ. of Puerto Rico, 1965. vii+59 pp. (paper). S, P.

Elementary Number Theory, 2nd ed. By Edmund Landau. Translated by Jacob Goodman, with exercises by Paul Bateman and Eugene Kohlbecker. Chelsea, New York, 1966. 256 pp. $4.95.

Elementary Methods in the Analytic Theory of Numbers. By A. O. Gel'fond and Yu. V. Linnik. Translated by D. E. Brown. Translation edited by I. N. Sneddon. Pergamon Press, New York, 1966. xi+232 pp. $9.80. "Many important problems in the modern analytic theory of numbers can be stated in terms of elementary mathematics and simple concepts such as that of a limit or just of an indefinitely increasing parameter. At the present time very many problems of the analytic theory of numbers are capable of solution by elementary methods and solutions have been published in journals and monographs. In this volume many of these solutions are collected, systematized to a certain extent and simplified where possible. . . . " Schnirelmann's method, Mann's theory, Erdös' theorem, Waring's problem, Hilbert-Kamke problem, distribution of primes, law of distribution of Gaussian primes, almost-prime Gaussian numbers, sieve of Eratosthenes, Atle Selberg's method, distribution of fractional parts of numerical sequences, integral points within contours, power residues, Hasse's theorem, Siegel's theorem, transcendence of certain number classes. S (16–18), P, L.

Topics from the Theory of Numbers. By Emil Grosswald. Macmillan, New York, 1966. xiv+299 pp. $8.50. ". . . rather little overlap with any other text I know of, except, of course, for the most fundamental topics . . . emphasis given to the historical point of view and the inclusion of references to a large amount of source material. . . . " Historical background, elementary number theory (divisibility, congruences, quadratic residue, arithmetical functions,) and topics from analytic and algebraic number theory (distribution of primes and Riemann zeta functions, proof of the prime number theorem, diophantine equations and Fermat's conjecture, ideal theory, proof of Fermat's conjecture for regular primes, partitions). Appendices on topics from analysis and algebra. T (15–17, one or two semesters), S, P.

Probability and Statistics

Elements of Probability Theory. By J. Bass. Translated by W. McKay. Translation editor A. Jeffrey. Foreword by E. W. Barankin. Academic Press, New York, 1966. xiv +249 pp. $9.75. Six chapters on the usual introductory topics lead to the law of large numbers and central limit theorem—described by the author as "the focal point of the course." There follow two chapters on random functions, two on statistics (estimation, confidence intervals, maximum-liklihood, tests, etc.), and 53 graded problems. Barankin, in his interesting foreword, praises the book for bringing to our students "some European sense of caution and discrimination" and for building up slowly with extensive explanation and illustration. T (15–16, especially for students in science and engineering).

Measurement and Analysis of Random Data. By Julius S. Bendat and Allan G. Piersol. Wiley, New York, London, 1966. ". . . a reference for practicing engineers and scientists." P.

Principles of Statistics. By M. G. Bulmer. M.I.T. Press, Cambridge, Mass., 1965. 214 pp. $7.50. "The aim of this book is to describe as simply as possible the fundamental principles and concepts of statistics. I hope that it may be useful both to the mathematician who requires an elementary introduction to the subject and to the scientist

who wishes to understand the theory underlying the statistical methods which he used in his own work." The approach is eclectic. Both frequency and degree of belief are considered and the style is discursive. A rather balanced presentation of the controversies over inference is given, but in the bibliography R. A. Fisher is cited seven times, while neither J. Neyman or E. Pearson appear at all! There are no exercises. S (14–15), P.

The Monte Carlo Method. The Method of Statistical Trials. By N. P. Buslenko, D. I. Golenko, Yu. A. Shreider, I. M. Sobol and V. G. Sragovich. Edited by Yu. A. Shreider. Translated from the Russian by G. J. Tee. Translation edited by D. M. Parkyn. Pergamon Press, New York, 1966. xii+381 pp. $12.50. "The book is intended for mathematicians, physicists and engineers who need to solve problems in applied mathematics." P, L.

Bibliography of Statistical Literature 1940–49. By Maurice G. Kendall and Alison G. Doig. Hafner, New York, 1965. 190 pp. $10.50. This is the second of three projected volumes covering the literature of statistics and probability from the sixteenth century. L.

Elements of Probability and Statistics. By Elmer B. Mode. Prentice-Hall, Englewood Cliffs, N.J. 1966. xii+356 pp. $8.75. Includes multinomial, bivariate binomial, and chi-square distributions, estimation, testing hypotheses (very little), regression, correlation, and Markov chains. T (precalculus).

Sequential Methods in Statistics. By G. Barrie Wetherill. Wiley, New York, 1966. x+218 pp. $5.50. ". . . a survey . . . with emphasis on practical importance. Detailed mathematical proofs are not given, but the logical basis of the methods is presented. . . . The chapter on sequential estimation brings out the difference between the Neyman-Pearson and Bayesian approaches . . . a set of problems at the end of each chapter, some of which lead to further research." S, P.

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor C. H. Gladman, Texas Western College, represented the Association at the dedication of the Mathematical Sciences Building at New Mexico State University on December 27, 1966.

University of Alberta, Edmonton: Assistant Professor Nadhla Al-Salam, University of Alberta, Calgary, and Dr. D. W. Boyd, University of Toronto, have been appointed Assistant Professors; Associate Professor W. A. Al-Salam, University of Alberta, Calgary, has been appointed Associate Professor; Assistant Professor J. W. Moon has been promoted to Associate Professor; Professor A. L. Dulmage has been appointed Associate

Dean, Faculty of Arts and Science, at the University of Manitoba; Professor A. E. Livingston has been appointed Professor at Oregon State University; Associate Professor D. W. Willett has been appointed Associate Professor at the University of Utah.

Arlington State College: Dr. B. B. Williams, University of Texas, has been appointed Assistant Professor; Professor B. M. Wall has accepted the position of Head of the Mathematics Department.

Bowling Green State University: Assistant Professor J. F. Leetch has been promoted to Associate Professor; Dr. C. E. Harrell, University of Texas, and Mr. J. F. Ramaley, Carnegie Institute of Technology, have been appointed Assistant Professors.

Brigham Young University: Dr. V. H. Miller, Montana State University, has been appointed Assistant Professor; Assistant Professor K. M. Larsen has been promoted to Associate Professor.

Brooklyn College: Dr. Howard Allen, Polytechnic Institute of Brooklyn, and Miss Marion S. Weiner, New York University, have been appointed Assistant Professors; Assistant Professor Margaret Y. Woodbridge has been promoted to Associate Professor.

California State Polytechnic College: Assistant Professors C. F. Gerald and C. T. Haskell have been promoted to Associate Professors.

University of Illinois: Dr. J. W. Brown, U.C.L.A., Dr. L. E. Claborn, Cornell College, Dr. R. L. Finney, Princeton University, and Dr. Phyllis G. Parr, Indiana State University, have been appointed Assistant Professors; Assistant Professors F. B. Knight, Hiram Paley, and N. J. Rothman have been promoted to Associate Professors; Dr. S. B. Bank has been promoted to Assistant Professor; Associate Professors Mary E. Hamstrom and J. H. Walter have been promoted to Professors.

Kenyon College: Associate Professor R. M. McLeod, University of Tennessee, has been appointed Associate Professor; Professor W. R. Transue has been appointed Professor at SUNY at Binghamton; Assistant Professor R. M. Fesq has been promoted to Associate Professor; Associate Professor W. D. Lindstrom has been promoted to Professor.

Michigan State University: Dr. G. D. Ludden, University of Notre Dame, Dr. C. R. MacCluer, University of Michigan, Assistant Professor R. C. O'Neill, University of Michigan, and Dr. C. E. Weil, University of Chicago, have been appointed Assistant Professors; Associate Professor John Wagner has been promoted to Professor.

University of Nebraska: Dr. M. D. Larsen, University of Kansas, and Dr. D. L. Skoug, University of Minnesota, have been appointed Assistant Professors; Assistant Professors S. E. Dickson and A. M. Fink have been promoted to Associate Professors.

New Mexico State University: Associate Professor J. E. Kist, Pennsylvania State University, has been appointed Visiting Associate Professor; Professor R. B. Crouch has been appointed Professor and Chairman of the Mathematics Department at Drexel Institute.

Northwestern State College: Mr. E. F. Ratliff, Jr., Oklahoma Baptist University, has been appointed Assistant Professor; Mr. D. R. Pitt, Jr., has been promoted to Assistant Professor.

Professor J. J. Gergen, Duke University, died on January 16, 1967. He was a member of the Association for thirty-three years.

Professor J. D. Hill, Michigan State University, died on January 4, 1967. He was a member of the Association for thirty-seven years.

Professor H. T. Muhly, University of Iowa, died on December 22, 1966. He was a member of the Association for sixteen years.

Dr. J. H. Waddell, Kitt Peak National Observatory, died in November, 1966. He was a member of the Association for seven years.

Professor Emeritus A. K. Waltz, Steubenville College, died on December 5, 1966. He was a member of the Association for forty-seven years.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

OCTOBER MEETING OF THE MINNESOTA SECTION

The fall meeting of the Minnesota Section of the MAA was held at the University of Manitoba in Winnipeg, Manitoba on October 29, 1966. There were 75 persons in attendance, including 53 members of the association. Professor Bernard Noonan of the University of Manitoba presided over the morning sessions; Professor Dale Varberg of Hamline University presided over the afternoon sessions. The sessions were held in University College.

At the business meeting a nominating committee for next year's officers was appointed. The following proposal was made: that each year the Minnesota Section send a letter of commendation to all Putnam contestants in the section who score within the top 25 percent in the national competition, inviting them to the spring meeting with a free luncheon at the courtesy of the section. In addition, the top 10 of these contestants will be awarded a year's subscription to the Mathematical Monthly.

The program of the sessions was as follows:

1. *A combinatorial problem*, by J. A. Ewell, University of Manitoba, introduced by H. Finlayson.
2. *Groups and graphs*, by C. T. Benson, University of Manitoba, introduced by Nora Losey.
3. *On subalgebra lattices of universal algebras*, by George Grätzer, University of Manitoba, introduced by Nathan Mendelsohn.
4. *Maximal binary determinants by electronic computer*, by Bernard Noonan, University of Manitoba, introduced by Roy Dowling.
5. *Critical cases of implicit function theory*, by H. I. Freedman, University of Minnesota.
6. *The international congress of mathematicians at Moscow*, by K. W. Wegner, Carleton College.
7. *Combinatorial problems in group theory*, by N. S. Mendelsohn, University of Manitoba (by invitation).
8. *Des films mathématiques (Avec des exemples)*, by Seymour Schuster, Minnemath Center at the University of Minnesota (by invitation).

WALBERT KALINOWSKI, *Secretary-Treasurer*

DECEMBER MEETING OF THE MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA SECTION

The annual fall meeting of the Maryland-District of Columbia-Virginia Section of the MAA was convened at Georgetown University, Washington, D. C. on December 10, 1966. Chairman T. L. Reynolds of the College of William and Mary, Williamsburg, Virginia, presided. Approximately 120 persons attended. The morning was devoted to short papers presented in two concurrent sessions.

During morning session I the following papers were presented:

1. *Minimum number of subsets to distinguish individual elements*, by P. R. Meyers, National Bureau of Standards, Washington, D. C.

Given a set S of cardinality m, the author determines the minimum cardinality $f(m)$ for a family F of subsets of S such that each $s \in S$ can be expressed as the intersection of some subfamily of F. The problem is solved in the following inverse form. For a given number n of subsets of S, find $g(n)$: the maximum number of elements of S which can be written as the intersection of some of these subsets. It is shown that $g(n)$ is the largest binomial coefficient for combinations of n things.

2. *A note on the Pell equation*, by Paul Devine, Jr., George Washington University.

The author proves that a necessary condition for the solvability of the Pell Equation, $x^2 - Ny^2$

$=-1$, N a positive, nonsquare integer, is that (1) $N=\alpha^2+\beta^2$, gcd $(\alpha, \beta)=1$, (2) α is odd, (3) α is a quadratic residue of N. There are 294 values of N, less than 10,000, for which (1) alone is necessary but not sufficient; the least value is $N=34$. The author observes that there are only 70 values of N, out of these 294, for which (1)–(3) are necessary but not sufficient; the least value is $N=505$.

3. *An extension of Rainville's classification of simple polynomial sets*, by Sister Mary Seraphine Bennett, Mt. Saint Agnes College.

4. *A note on abelian p-groups and their endomorphism rings*, by Eleanor Green Dawley, Hampton Institute.

This note gives an alternate proof of the fact that the direct sum of a bounded abelian p-group and a divisible abelian p-group is determined by its endomorphism ring. The proof is more simple than Kaplansky's classical proof of this result and does not involve the extensive ring theory utilized by Kaplansky.

5. *Ideals and filters*, by C. E. Aull, Virginia Polytechnic Institute.

DEFINITION 1. *An ideal A is an f-ideal in a commutative semigroup S if for $a, b \in A$, there exists $c \in A$ such that $cx=a$ and $cy=b$ have solutions in S.*

All semigroups and rings are commutative. The author proves that the filters are identical with the f-ideals of the semigroup of all nonnull subsets of a set with the operation of set union; an f-ideal in a semigroup which is an ideal of another semigroup is also an f-ideal of the latter semigroup; a cancellation semigroup has an identity iff all its principal ideals are f-ideals; an f-ideal in the semigroup under multiplication of a ring is always an ideal in the ring.

During morning session II, the following papers were presented:

1. *The solution of the Dirichlet problem for Poisson's equation by finite difference methods*, by B. E. Hubbard, Institute for Fluid Dynamics and Applied Mathematics, University of Maryland.

With the advent of modern high speed computers it has become feasible to calculate approximate solutions to boundary value problems with great accuracy.

Difference methods are quite often used because of their simplicity and generality. It thus becomes a matter of great interest to study the rates of convergence of such solutions to the unknown function as the mesh parameter approaches zero. It is of particular interest to study the effect on such convergence rates under various assumptions on the regularity of the data (and hence of the solution itself). This paper concerns itself principally with this latter question.

2. *Asymptotic analysis of a first-moment integral and its derivatives*, by A. J. Goldman, National Bureau of Standards, Washington, D. C.

Let $f(p)$ be the first moment, with respect to point P, of a planar mass distribution about which one knows only that it is concentrated in a disk D of radius R around its (known) center of gravity C. For P far from D, $f(P)$ and its derivatives (with respect to the coordinates of (P) look like the corresponding expressions for an equivalent point mass at C. Error bounds are derived for this asymptotic relation. (Joint work with C. Witzgall, arising in a study of optical location methods for the Post Office Department.)

3. *Stability of nonlinear nonautonomous systems by the stroboscopic method*, by Abolghassem Ghaffari, Goddard Space Flight Center, Greenbelt, Maryland.

The stroboscopic method (N. Minorsky, Nonlinear oscillations, Van Nostrand, 1962) is particularly advantageous in connection with nonlinear nonautonomous systems inasmuch as it permits replacing the problem of stability of a periodic solution by the problem of stability of equilibrium.

Applying the stroboscopic criterion to the nonlinear non-autonomous differential equation $\ddot{x}+(a+bx^2)\dot{x}+x=c\cos t$ and limiting the analysis to the first-order approximation only, the author finds that the conditions of stability are: $a<0$, $b>0$ (case of van der Pol equation with an external periodic excitation $c\cos t$), and the instability condition is $b<0$.

4. *Let's modernize the teaching of modern mathematics*, by G. L. Engel, U. S. N. W. L., Dahlgren, Virginia.

A review and summary of available and proposed systems in Computer Assisted Instruction is presented. The author indicates the interest of CAI as a tool in training and makes an appeal for the study of CAI applications in the teaching of mathematics in the colleges of the district.

5. *Systems of non-linear equations*, by M. A. Hyman, IBM Corporation, Gaithersburg, Maryland.

The author is concerned with the problem of computing best (in the sense of least squares) parameters to fit non-linear functions to observational data. In the classical approach one solves a sequence of linear problems hoping that the sequence of solutions converges to the solution vector of the non-linear problem; in practice this sequence often does not converge. Further, the intermediate linear problems are ill-conditioned. K. Levenburg's work on "damped least squares" (Qu. Appl. Math., 1944) assures convergence and avoids ill-conditioning; this is related to recent work by E. Weiss and W. Goodyear. The paper concludes with brief mention of (a) the "quasi-inverse" of F. Ditto, (b) recent functional-analytic results of Robert-Shipman, and a zero-finding algorithm (Hyman, 1961).

Following a short business meeting during which Prof. M. G. Humphreys, Prof. S. S. Saslow and Dr. Daniel Shanks were appointed to the Nominating Committee, the afternoon session focused on *A General Curriculum in Mathematics for Colleges*. Professor M. Gweneth Humphreys of Randolph-Macon Woman's College, Lynchburg, Virginia, reviewed the GCMC, after which brief comments on its reception by the universities and colleges were presented by Professors W. L. Duren, University of Virginia, J. A. Hummel, University of Maryland and G. S. Quinn, The American University.

G. N. TRYTTEN, *Secretary*

FEBRUARY MEETING OF THE NORTHERN CALIFORNIA SECTION

The annual meeting of the Northern California Section of the MAA was held at the University of California, Davis on February 4, 1967. Professor L. H. Lange, Chairman of the Section, presided; Professor E. M. Beesley was Program Chairman. There were 120 persons in attendance, 85 of whom were members of the Association.

At the business meeting the following officers were elected: Chairman, Professor C. A. Hayes of the University of California, Davis to succeed Professor L. H. Lange of San Jose State College; Vice-Chairman, Dr. Henry Osner of Modesto Junior College to succeed Professor Hayes; Secretary-Treasurer, Professor G. L. Alexanderson of the University of Santa Clara to succeed Dr. Joel Brenner of Stanford Research Institute.

Also at the business meeting Professor H. L. Alder reported on the national meeting in Houston and Professor D. W. Blakeslee reported on the meetings of the Board of Governors. Professor Hayes presented the findings of the Reaction Committee to the CUPM Report on *A General Curriculum in Mathematics for Colleges*. The Committee's report will be forwarded to CUPM. A report on the activities of the High School Contest Committee was submitted by Mr. William Landis, Contest Committee Chairman.

The following papers were presented:

1. *Some results on Sturm-Liouville differential systems defined on continua and discrete sets*, by J. F. Schipper, Sacramento State College.

2. *Some Properties of Hahn Polynomials*, by R. J. Levit, San Francisco State College.

From the orthogonality property it follows that the Hahn polynomial of degree m, $P_m^{(\alpha,\beta,\gamma)}(x)$, has m real distinct zeros in the interval $(0, \gamma-1)$, provided $\alpha, \beta > -1$ and γ is an integer $> m$. In the present paper this is extended to all real $\gamma > m$. A new symmetry property then leads to a similar result for $\gamma < -(m+\alpha+\beta)$ with the zeros in $(\beta+\gamma, -\alpha-1)$. Examples show that, if the restrictions on the parameters are further relaxed these conclusions may fail. Other results concern separation of zeros and interlacing of zeros of Hahn polynomials with appropriately related degrees or parameter values.

3. *Nonroutine problems for naive programmers*, by Dmitri Thoro, San Jose State College.

Computer-oriented problems of a number-theoretic or combinatorial nature were considered; some led to a machine-language program, others a pencil and paper solution.

4. *Sifting for answers*, by D. H. Lehmer, University of California at Berkeley, (invited address).

5. *Predicativity: mathematics of the definable*, by Solomon Feferman, Stanford University, (invited address).

The meeting concluded with a panel discussion on "The Role of Axiomatics and Problem Solving." Panel members were E. G. Begle, Stanford University; H. M. Bacon, Stanford University; C. M. Larson, San Jose State College; L. D. Hawkinson, Gunn High School, Palo Alto; Leon Henkin, University of California at Berkeley.

G. L. ALEXANDERSON, *Secretary-Treasurer*

PROPOSED AMENDMENT TO THE BY-LAWS OF THE MAA

At the meeting of the Board of Governors held on January 25, 1967, in Houston, the Secretary was instructed to submit to a vote of the membership an amendment to Article V of the By-Laws, which will spell out more specifically the procedures for the creation and modification of Sections of the Association. In accordance with these instructions, a motion will be made at the business meeting of the Association to be held at the University of Toronto on Tuesday, August 29, 1967, to amend Article V of the By-Laws to read as follows:

ARTICLE V—SECTIONS

1. In the interest of more effective promotion of the objectives of the Association on a local level, the United States, Canada and their possessions shall be subdivided by the Board of Governors into non-overlapping geographical areas, and a Section of the Association shall be established in each of these areas. The subdivision into non-overlapping areas may be changed by the Board, upon recommendation by the Committee on Sections (see paragraph 7).

2. Each member of the Association residing in the United States, Canada or their possessions shall belong to one and only one Section. He will belong to the Section in whose geographic area he resides, except that a member who resides in one area and is employed in a different area may elect the Section to which he prefers to belong. Any member may petition the Committee on Sections for reassignment of his membership to another Section.

3. Each Section shall adopt a set of By-Laws which, along with any subsequent changes, must be approved by the Board. The geographic area covered by a Section shall be described in the By-Laws for the Section.

4. If there are members of the Association residing in a geographic area in which no Section has been organized, any ten or more members of this Association residing or employed in this area may petition the Board for authority to organize a Section covering that area.

5. A group of not less than twenty-five members of an existing Section may petition the Board to partition the area and the Section into two or more Sections. The Board shall have authority to approve or deny this petition. The Board may specify conditions under which such action may be accomplished. It may conduct a poll of some or all members of the Association in the Section to determine the advisability of allowing the proposed partition of the Section. If separate Sections are approved then each new Section must prepare its own set of By-Laws to be approved by the Board.

6. A group of not less than twenty-five members residing or employed in that part of the area of an existing Section which they desire to become part of another existing Section may petition the Board to redefine the geographic boundaries of the Sections affected. The Board shall have authority to approve or deny this petition. It may conduct a poll of some or all members of the Sections involved to determine the advisability of permitting such action.

7. There shall be a standing Committee on Sections through which the Board shall maintain general supervision over the activities of all Sections. This Committee, in particular, shall study all matters involving creation of Sections or modification of boundaries of Sections and make appropriate recommendations to the Board.

8. The Association shall not be obligated to pay from its treasury any of the expenses of a Section except as the Board may provide.

HENRY L. ALDER, *Secretary*

THE EMPLOYMENT REGISTER

During the summer meeting at the University of Toronto, the Mathematical Sciences Employment Register will be open for the scheduling of interviews between applicants and employers.

The Employment Register, which is sponsored by the American Mathematical Society, the Mathematical Association of America, and the Society for Industrial and Applied Mathematics, will be located on the first floor of Sidney Smith Hall, and will be open from Tuesday, August 29, through Thursday, August 31, from 9:00 A.M. to 5:00 P.M. on each of the three days.

Registration for the Employment Register is separate and apart from meeting registration, and it is, therefore, most important that both applicants and employers sign in at the Employment Register Desk as early as they can on Tuesday morning. A separate visual index will be maintained for Employment Register use only. Appointments may be requested only with applicants and employers who have actually signed in at the Register.

There is no charge for registration except when the late registration fee of $5.00 for employers is applicable. Provision will be made for anonymity of applicants upon payment of $5.00 to defray the cost involved in handling such a listing.

Applicants and employers who wish to be listed should write to the Mathematical Sciences Employment Register, P.O. Box 6248, Providence, Rhode Island 02904, for applicant qualification forms or position description forms. These forms must be completed and returned to the Employment Register not later than July 15, 1967, in order to be included in the August lists. Those forms which arrive too late to be included in the printed lists are taken to the meeting where they may be seen by applicants and/or employers who are interested in them. The printed lists will be mailed to subscribers during the first week in August. Lists can be ordered from the Employment Register office in Providence. They will also be available at the meeting.

A subscription to the lists, which includes three issues (January, May, and August) of both the applicants list and the positions list is available for $15.00 a year; individual issues of both lists may be purchased for $7.50; single copies of the positions list only may be purchased for $3.00. Checks should be made payable to the American Mathematical Society and sent to the address given above.

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN
ILLINOIS
INDIANA
IOWA
KANSAS
KENTUCKY
LOUISIANA-MISSISSIPPI, Mississippi State College for Women, Columbus, February 16–17, 1968.
MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA
METROPOLITAN NEW YORK
MICHIGAN
MINNESOTA
MISSOURI
NEBRASKA
NEW JERSEY
NORTHEASTERN, Mt. Allison University, Sackville, New Brunswick, June 23–24, 1967.
NORTHERN CALIFORNIA
OHIO
OKLAHOMA-ARKANSAS
PACIFIC NORTHWEST, University of Montana, Missoula, June 16–17, 1967.
PHILADELPHIA, University of Delaware, Newark, November 18, 1967.
ROCKY MOUNTAIN
SOUTHEASTERN
SOUTHERN CALIFORNIA, Loyola University of Los Angeles, March 9, 1968.
SOUTHWESTERN, New Mexico State University, University Park, Spring 1968.
TEXAS
UPPER NEW YORK STATE
WISCONSIN

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, N. Y., December 26–31, 1967.
AMERICAN MATHEMATICAL SOCIETY, Toronto, Ontario, Canada, August 29–Sept. 1, 1967.
AMERICAN SOCIETY FOR ENGINEERING EDUCATION, Michigan State University, June 19–22, 1967.
ASSOCIATION FOR COMPUTING MACHINERY, Sheraton-Park, Washington, D. C., August 29–31, 1967.
ASSOCIATION FOR SYMBOLIC LOGIC
CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.
INSTITUTE OF MATHEMATICAL STATISTICS
NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, McGill University, Montreal, August 21–24, 1967.
OPERATIONS RESEARCH SOCIETY OF AMERICA
PI MU EPSILON, Toronto, Ontario, Canada, August 29–30, 1967.
SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, Shoreham Hotel, Washington, D. C., June 12–15, 1967. (Symposiums on applied probability and fluid dynamics.)

A Modern Approach to Mathematics . . .

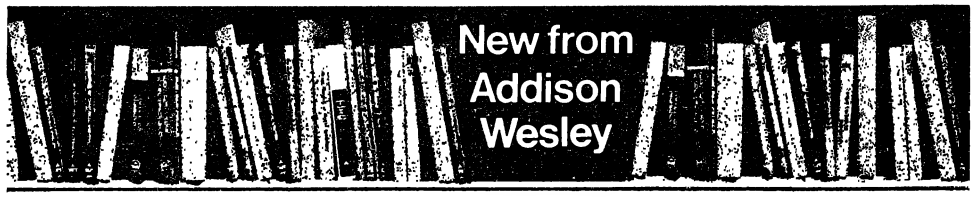
CALCULUS WITH ANALYTIC GEOMETRY AND LINEAR ALGEBRA

by LEOPOLDO V. TORABALLA, *New York University*

This new text, designed for use in an introductory undergraduate course, deals with the standard material of elementary calculus. In accordance with recent proposals of the Committee on the Undergraduate Program in Mathematics, which state, "The basic concepts should be introduced in the same spirit in which they are used by working mathematicians, and proofs ought to have the same clarity and elegance which distinguishes all first rate mathematics," the author uses a thorough and direct approach on the level of rigor demanded by modern mathematics.

The book begins with a thorough postulational presentation of the real number system and follows this with a well-motivated, simple, yet logically adequate development of the topology of the space of real numbers.

SPECIAL FEATURES:



- A two-level system, with instructions for the use of the book on each level. The first level corresponds to an introductory course—the second level, an honors course.
- Since the central theme of the calculus is embodied in the statement of the relation between the derivative and the integral, these two concepts are presented together.
- A treatment of linear algebra is included to prepare the student for the study of functions of several variables.
- Presentation of the analytic geometry of three-dimensional Euclidean space.
- Intuitive discussions introduce new concepts; heuristic proofs generally preceed formal proofs.
- Diversity of exercises which range from elementary problems dealing with applications in many fields to advanced exercises that demand facility in both application and theory.

CONTENTS

Introduction: Basic Concepts of Set Theory. The Real Number System. Functions, Mappings, and Graphs. The Derivative and the Integral. Introduction to the Applications of the Integral. The Derivative: Introduction to the Applications of the Derivative. Plane Analytic Geometry. Elementary Functions. Applications of the Derivative. The Search for Primitives. Applications of the Integral. Further Applications of the Integral. Infinite Series of Constants. Infinite Series of Functions: Power Series. Linear Algebra. The Euclidian Vector Spaces. Analytic Geometry of E^3. Functions of Two or More Real Variables. Multiple Integrals. Applications of the Multiple Integral. Appendices. Answers to Exercises. Subject Index.

1967, 920 pp., $11.95

For Introductory Calculus and Analytic Geometry Courses . . .

CALCULUS: Complete
CALCULUS: Part I ■ CALCULUS: Part II

By Edwin E. Moise, *Harvard University*

WHAT USERS ARE SAYING ABOUT THIS TEXT—

"A most challenging and refreshing approach. This should make calculus live for the student."

"It is an outstanding book in every respect, with clear explanations, as well as rigorous proof of all theory. Excellent problem sets develop the theory fully."

"First class. Makes other books seem old-fashioned."

"Excellent. Just what you expect of Professor Moise. I like his motivation, spiral approach, and selection of problems."

CALCULUS: Part I, 498 pp, 529 illus. $8.95

SPECIAL FEATURES:

- The spiral process is used throughout with the more difficult ideas being presented in a series of different forms, in ascending order of difficulty, generality, and exactitude.
- The text is available in either two volumes or in a single edition.
- Stress is placed on careful motivation of the ideas in terms of concrete interpretations.
- Three chapters of linear algebra as well as topics in differential equations are included in Part II.

CALCULUS: Part II, 773 pp, 168 illus. $7.50

CALCULUS: Complete, $12.50

MODERN COLLEGE ALGEBRA
Second Edition

By Elbridge P. Vance, *Oberlin College*

When the first edition of this highly successful college algebra text was being written, the influence of CUPM, SMSC, and the Commission on Mathematics of the College Entrance Examination Board upon mathematics at this level was already seriously felt. Since that time, certain other suggestions have been made by various influential groups. It is because of the changing mathematical world, and the suggested introduction of additional new topics that a new edition of this book seemed appropriate.

Special Features of Second Edition . . .

1. This edition has included new material on matrices, and a new approach to vectors, both strongly recommended at this level and both perfect preparation for later courses in linear algebra.
2. Several references are made to computing machines and methods used in this field.
3. The problems in this new edition have been augmented. Also, there are four new sets of review problems included at appropriate places.
4. Some problems emphasize the important ability to manipulate, while others deal with more theoretical ideas. *287 pp, 57 illus. $6.95*

FOUNDATIONS OF CONTEMPORARY MATHEMATICS: With Applications in the Social and Management Sciences.

By LOUIS O. KATTSOFF and ALBERT J. SIMONE, both of Boston College.

Designed as a basic two-semester course for social and management sciences, this text covers calculus, an introduction to statistical decision theory and mathematical statistics. Sets and functions are introduced at the start and used consistently throughout. **Off Press.**

CALCULUS IN THE FIRST THREE DIMENSIONS.

By SHERMAN K. STEIN, University of California, Davis.

This introductory calculus text for a one-year course stresses fundamentals and offers a broad range of applications in economics, the physical sciences, etc. It deals with such subjects as the definitive integral, the derivative, the law of means, maxima, series, etc. **613 pp., $9.95.**

FUNDAMENTALS OF COLLEGE ALGEBRA.

By CARL B. ALLENDOERFER, University of Washington; and CLETUS O. OAKLEY, Haverford College.

This modern treatment for the regular course offers much more than just "college algebra": it includes sets and logic; an unusually careful discussion of mathematical induction; an introduction to matrix and vector algebra; and stress on solution of inequalities in one and two variables. **446 pp., $7.50.**

COLLEGE ALGEBRA, Fifth Edition

By PAUL K. REES, Louisiana State University; and FRED W. SPARKS, Professor Emeritus, Texas Technological College.

The new edition of this highly teachable text features axiomatic rigor, using modern terminology and the theory of sets rather than the traditional, relatively looser approach. It presents the essentials for further progress in clear, concise style. Graded problems are provided a normal lesson apart. **Off Press.**

BASIC CONCEPTS OF MATHEMATICS.

By CHARLES G. MOORE and CHARLES E. LITTLE, both of Northern Arizona University.

Not a calculus text, this book is designed as a text for a one- or two-semester survey of mathematics. It acquaints liberal arts or education majors taking their final math course with the point of view of the mathematician. **Off Press.**

ELEMENTARY MATHEMATICS: A Modern Approach.

By JACK D. WILSON, San Francisco State College.

This text is designed for introductory courses where students are preparing for careers in elementary education. It is organized to present instruction in both conventional and modern mathematics, and its contents follow the recommendations of the CUPM. **400 pp., $7.50.**

FUNDAMENTAL MATHEMATICS, Third Edition.

By THOMAS L. WADE and HOWARD E. TAYLOR, both of Florida State University.

In the new edition of this well-established introductory college text, topics proceed from a basis in sets and are discussed in modern terminology. There is increased emphasis on structure in fundamental mathematics and more use of the concept of set. **Off Press.**

MODERN COLLEGE ALGEBRA.

By FLOYD LAMAR BLANTON and JAMES EARL PERRY, both of Abraham Baldwin College of The University System of Georgia.

This modern approach preserves the traditional basic material of college algebra and includes special, non-sequential topics to challenge adventurous students. It features the axiomatic presentation of the basic ideas of algebra within the framework of modern set terminology and elementary rules of logic. **288 pp., $6.95.**

EXAMINATION COPIES AVAILABLE ON REQUEST.

McGRAW-HILL BOOK COMPANY

330 West 42nd Street, New York, N. Y. 10036

INTRODUCTORY ALGEBRA FOR COLLEGE STUDENTS

By RICHARD E. JOHNSON, *University of New Hampshire,* LONA L. LENDSEY, *Oak Park and River Forest High School,* and WILLIAM E. SLESNICK, *Dartmouth College.* Teacher's Manual.

The purpose of this text is to provide a one-semester course in beginning algebra for students studying algebra for the first time, or reviewing the subject. Algebra is presented as a logically structured system. Although the real number system is the basis for most of the material, imaginary numbers are presented in the final chapter. Definitions are precise, and the properties of the real number system are developed from an intuitive point of view.

613 pp. $5.80

MATRICES AND LINEAR TRANSFORMATIONS

By CHARLES G. CULLEN, *University of Pittsburgh.*

The first five chapters of this book on linear algebra comprise a one-term text for science, engineering and mathematics students which covers those topics most frequently encountered in applications. Only a first course in calculus and analytic geometry is required. Aimed at the sophomore-junior level, the text approaches the subject from the matrix theory point of view rather than from the more abstract approach using linear transformations.

227 pp. $8.95

AN INTRODUCTION TO VECTOR FUNCTIONS

By JAMES A. HUMMEL, *University of Maryland.*

At the sophomore-junior level, this book offers material for a first course after calculus. It provides the mathematics needed for applications, and is intended mainly for engineers and physicists. The book is carefully and clearly written in the modern mathematical style (theorem, proof, etc.).

Coverage includes vector spaces, linear transformations, determinants, matrices, functions of several variables, differentials, integration, an introduction to curves and surfaces, and vector analysis. In press

A FIRST COURSE IN ABSTRACT ALGEBRA

By JOHN B. FRALEIGH, *University of Rhode Island.*

Aimed at the average mathematics major, this text has the primary objective of achieving maximum depth and comprehension in a first course. The book is designed to teach material of a level previously available only in texts intended for honors students.

The coverage constitutes a basic introduction to modern algebra, exclusive of linear algebra.

In press

INTRODUCTION TO ANALYTIC FUNCTIONS

By WILFRED KAPLAN, *University of Michigan.*

The present book is designed to provide an elementary introduction to functions of complex variables and their applications, for senior and graduate students of science and engineering. The text is based directly on Chapter Nine of the author's *Advanced Calculus,* and also includes a completely new chapter on analytic functions of several complex variables, coverage rarely made accessible at this level.

212 pp. 78 illus. $7.95

MATHEMATICS FOR LIBERAL ARTS

By MORRIS KLINE, *New York University.*

Intended for liberal arts and terminal students, this book is a revision and abridgement of the author's *Mathematics: A Cultural Approach.* This revision aims to meet special needs: courses for students who should have a little more review and drill on elementary concepts and techniques, courses for elementary school teachers, and one-semester twelfth-year high school or college courses.

577 pp. 212 illus. $8.95

INTRODUCTION TO MODERN ABSTRACT ALGEBRA

By DAVID M. BURTON, *University of New Hampshire.*

This book is designed for an undergraduate course in abstract algebra. While all of the important topics are covered in some detail, the emphasis is on ring theory. A prerequisite required for an understanding of this text is the usual material covered in an introductory calculus course. In press

EDITORIAL CORRESPONDENCE should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with $\det [a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are \$6.00 (\$8.00 in 1968). For nonmembers the subscription price is \$10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

ON A THEOREM IN GEOMETRY

DANIEL PEDOE, University of Minnesota

If four circles in a plane touch each other externally, and if ϵ_1, ϵ_2, ϵ_3, and ϵ_4 denote their curvatures (that is, the reciprocals of their radii), then the following relation holds between them:

$$2(\epsilon_1^2 + \epsilon_2^2 + \epsilon_3^2 + \epsilon_4^2) = (\epsilon_1 + \epsilon_2 + \epsilon_3 + \epsilon_4)^2.$$

A statement of this theorem, without proof, but with a descriptive poem attached, appeared in *Nature*, an English scientific journal, in 1936 [12]. The author was Frederick Soddy, distinguished by his pioneering work on isotopes. A year later a generalization of the theorem to $n+2$ spheres in mutual contact, lying in Euclidean space of n dimensions, was published by Thorold Gossett in the same journal [7]. Again, no proof was given, but an extra verse for the Soddy poem was suggested.

The title of the Soddy poem, "The kiss precise," is probably enough to indicate its flavour. Coxeter [3 p. 15] quotes a complete verse.

(It is perhaps worth noting, as a warning to aspiring poetasters, that *Nature* is averse to *belles lettres* these days. A few years ago Sir Alexander Oppenheim submitted the statement of an attractive theorem in geometry, accompanied by a graceful descriptive poem which my wife had written at his suggestion, but *Nature* rejected the joint offering.)

Two proofs of what, for the moment, we shall call the Soddy theorem have appeared in textbooks. One is elementary, uses trigonometry, and does not lend itself to a possible generalization [Coxeter, **3**, p. 15]. The second is apparently simple, but it is not elementary, and uses the methods of the Grassmann calculus as applied to circles by Homersham Cox in 1883 [2]. But this proof in Forder's book [6] can be generalized. We shall return to it later. There is no reference to Soddy in the Forder proof, and in fact the theorem just occurs as one of a number of worked examples, on p. 339.

The Soddy theorem is an interesting one because it can be viewed from a number of different mathematical angles. We approach it heuristically in the first instance, using arguments which may need amplification, but which do suggest possible lines of attack on the proof.

We do not know *a priori* that a relationship of the Soddy type holds between four circles which touch each other. We do know, from the Apollonius theorem, that eight circles touch three given circles in general position [Pedoe, **11**, p. 23]. When these circles are specialized, some of the eight touching circles may coincide, and, as in all enumerative problems, the coincident solutions of the problem must be counted with a certain multiplicity [Hodge and Pedoe, **9**, vol. II, p. 127].

Suppose now that the three given circles C_1, C_2, C_3 all touch each other. Then since C_1 touches itself, it is a solution of the Apollonius problem. So is C_2, and

so is C_3. The multiplicity with which each of these circles must be counted in the solution of the Apollonius problem is (a) greater than 1, and (b) the same for each circle. Let it be n. Then since $3n$ must not exceed 8, we must have $n=2$, and therefore we expect only two other circles to touch three circles which touch each other.

If there is an algebraic relation connecting the curvatures of four circles which touch each other, the above reasoning shows that it must be in the form of a quadratic polynomial equated to zero. In fact, it must be a quadratic *form*, since if we multiply the curvatures of three of the circles by a factor k, by a similarity transformation, the curvature of the fourth circle increases likewise by a factor k. Finally, the form must remain unchanged if we interchange any two of $\epsilon_1, \epsilon_2, \epsilon_3, \epsilon_4$, the curvatures of the four circles. It must therefore equal

$$p\,(\sum \epsilon_i^2) + q \sum \epsilon_i\epsilon_j \quad (1 \leqq i < j \leqq 4).$$

Now, if two circles touch each other externally, and t is the length of a common tangent, we have at once

$$t^2 = (r_1 + r_2)^2 - (r_1 - r_2)^2 = 4r_1r_2,$$

where r_1 and r_2 are the radii. Let three circles of radii r_1, r_2 and r_3 respectively touch each other, and a given line at P, Q and R respectively. Then we have

$$PQ^2 = 4r_1r_2, \quad QR^2 = 4r_2r_3, \quad \text{and} \quad PR^2 = 4r_1r_3.$$

Since $PQ \pm QR = PR$, this leads to

$$1/\sqrt{r_3} \pm 1/\sqrt{r_1} = 1/\sqrt{r_2},$$

which, in terms of the curvatures is $\sqrt{\epsilon_1} \pm \sqrt{\epsilon_2} \pm \sqrt{\epsilon_3} = 0$. This, in rational form, is

$$\sum \epsilon_i^2 - 2 \sum \epsilon_i\epsilon_j = 0 \quad (1 \leqq i < j \leqq 3).$$

Now, the line has curvature $\epsilon_4 = 0$, and this relationship in the case $\epsilon_4 = 0$ indicates (a) that there is an algebraic relation between the four curvatures ϵ_i $(i=1, \cdots, 4)$ of four circles which touch each other and (b) it must be

$$\sum \epsilon_i^2 - 2 \sum \epsilon_i\epsilon_j = 0 \quad (1 \leqq i < j \leqq 4),$$

and this is the Soddy theorem.

This method can be generalized, if we use the theorem that there is a polynomial relation between the squares of the mutual distances of $n+2$ points in Euclidean space of n dimensions. In two dimensions the relation for four points P_i $(i=a, b, c, d, 4)$ can be written:

$$\sum (P_aP_b)^2(P_bP_c)^2(P_cP_d)^2 - \sum (P_aP_b)^2(P_bP_c)^2(P_cP_a)^2 - \sum (P_aP_b)^2(P_cP_d)^4 = 0,$$

where the summations are over all permutations of unordered pairs, and the first summation contains 12 terms, the second 4, and the third 6. This relation

expresses the fact that the volume of the tetrahedron formed by the points is zero, and can be traced back to L. N. M. Carnot [Guggenheimer, **8**].

We can use this relation to indicate the form of the Soddy theorem for five spheres in mutual contact in Euclidean space of three dimensions. We assume that one sphere is a plane, so that the other four spheres touch this plane, and, as above, using the formula $4(P_aP_b)^{-2}=\epsilon_a\epsilon_b$, which is also true for spheres of curvatures ϵ_a, ϵ_b touching a line at P_a, P_b, we obtain the relation

$$\sum \epsilon_i^2 - \sum \epsilon_i\epsilon_j = 0 \quad (1 \leqq i < j \leqq 4),$$

which indicates that the Soddy relation for 5 spheres in mutual contact in Euclidean space of 3 dimensions is

$$\sum \epsilon_i^2 - \sum \epsilon_i\epsilon_j = 0 \quad (1 \leqq i < j \leqq 5),$$

or

$$3\left(\sum \epsilon_i^2\right) = \left(\sum \epsilon_i\right)^2 \quad (i = 1, \cdots, 5).$$

It is worth noting that if we attempt to generalize the method used for circles to show that two spheres touch each of four spheres (in space of 3 dimensions) which are in mutual contact, we run into a serious snag. We may assume, from algebraic considerations that the number of spheres which touch four spheres in general position in space of 3 dimensions is $2^4=16$. If the four given spheres touch each other, and each counts with multiplicity n in the total count, we have $4n+x=16$, where we know that n exceeds 1, and we should like x to equal 2. This will not work. The reason why this method breaks down is that the Soddy theorem is a theorem of *real* Euclidean space, and we cannot expect an algebraic treatment, which gives complex solutions, always to fit the real case.

If we take four sufficiently small spheres round the vertices of a tetrahedron, they will be touched by a sphere that approximates to the circumsphere of the tetrahedron. Noting that each small sphere can lie inside or outside the approximating circumsphere, we see that there are 16 such Apollonian spheres. If the algebraic details are carried out (Prof. Coxeter has done this), it is found that when the radii of the small spheres increase steadily towards the situation of mutual contact, 6 of the Apollonian spheres cease to be real, and 8 of the remaining 10 coincide in pairs with the 4 given spheres, leaving 2 real spheres which touch the 4 given spheres. We wish to find these without having recourse to the algebraic manipulation.

We recollect that our derivation of the Soddy theorem in the plane used properties of the real line. We accordingly begin our investigations again, using a method that proves the Soddy theorem in the plane, generalizes to n dimensions, and makes essential use of real Euclidean space.

To show that two circles touch three given circles in a plane which already touch each other, we invert, with center of inversion at a point of contact. The

inverse figure consists of two parallel lines, touched by a circle. Any circle which touches the two lines must have the same radius as the circle already touching the lines, and there are two such circles which touch the circle already touching, *one on each side* of this circle.

We observe that the quadratic equation

$$p(\sum \epsilon_i^2) + q \sum \epsilon_i \epsilon_j = 0 \quad (1 \leqq i < j \leqq 4),$$

must be such that if $\epsilon_3 = \epsilon_4 = 0$ (the two lines each having curvature zero) the equation is identically satisfied by $\epsilon_1 = \epsilon_2$, since the circles have the same radius. Hence

$$p(2\epsilon_1^2) + q(\epsilon_1^2) = 0;$$

we may take $p = 1$ and $q = -2$, and obtain the Soddy theorem.

For spheres in three dimensions, we suppose that we are given four spheres which touch each other, and we wish to find how many spheres touch these four spheres. Inverting with respect to a point of contact of two of the spheres, we obtain two parallel planes, each of which is touched by spheres C_1 and C_2 which touch each other. Any sphere which touches the two planes must have radius equal to that of the equal spheres C_1 and C_2. We can construct two equilateral triangles, of which one side is the join of the centers of C_1 and C_2, the triangles lying in the plane through the centers parallel to the two parallel planes in the figure, and the new vertices, *on either side* of the join of the centers, are centers of spheres which touch the two planes and C_1, C_2.

Again the properties of real Euclidean space have been used, and we deduce that there is a form

$$p(\sum \epsilon_i^2) + q \sum \epsilon_i \epsilon_j = 0 \quad (1 \leqq i < j \leqq 5)$$

connecting the curvatures of five spheres which touch each other in real Euclidean space of three dimensions. Again, this form is to be identically satisfied if we put $\epsilon_4 = \epsilon_5 = 0$, and $\epsilon_1 = \epsilon_2 = \epsilon_3$. This leads to

$$p(3\epsilon_1^2) + q(3\epsilon_1^2) = 0;$$

we may take $p = 1$, $q = -1$, and deduce once more that the Soddy theorem in three dimensions is

$$3 \sum \epsilon_i^2 = (\sum \epsilon_i)^2 \quad (i = 1, \cdots, 5).$$

The extension to real Euclidean space of n dimensions is immediate. We assume that we have $n+1$ spheres which touch each other, and we invert with respect to a point of contact of two spheres. The inverse figure consists of two parallel hyperplanes, each of which is touched by $n-1$ spheres which also touch each other. These spheres must all have the same radius, and any sphere which touches the two hyperplanes also has this radius. If such a sphere also touches

the $n-1$ equal spheres, its center must be at one of two points, and these points are mirror images of each other in the flat space of $n-2$ dimensions spanned by the centers of the $n-1$ spheres. Each of the two centers completes, with the $n-1$ centers, a regular simplex in the unique $(n-1)$-dimensional space which contains the $n-1$ centers and is parallel to the two hyperplanes.

If the curvatures of the $n+2$ spheres in real Euclidean n-space are $\epsilon_1, \cdots, \epsilon_{n+2}$, then if all these spheres touch each other, we have a relation

$$p(\sum \epsilon_i^2) + q(\sum \epsilon_i\epsilon_j) = 0, \quad (1 \leqq i < j \leqq n+2).$$

If we put $\epsilon_{n+1} = \epsilon_{n+2} = 0$, this relation is identically satisfied by $\epsilon_1 = \epsilon_2 = \cdots = \epsilon_n$, so that

$$pn\epsilon_1^2 + q\binom{n}{2}\epsilon_1^2 = 0,$$

and this is satisfied by taking $p = n-1$, and $q = -2$, so that the statement of the Soddy theorem for n dimensions is

$$(n-1)(\sum \epsilon_1^2) - 2(\sum \epsilon_i\epsilon_j) = 0, \quad (1 \leqq i < j \leqq n+2)$$

or

$$n(\sum \epsilon_i^2) = (\sum \epsilon_i)^2 \quad (i = 1, \cdots, n+2).$$

This is the generalization given by Gossett without proof [7].

It was at this point in my investigations that I received a postcard from Prof. Makowski of Warsaw, Poland. He had seen a short reference to my work in *Mathematical Notices*, and his card drew my attention to a paper in Danish by David Fog entitled "The position of a point with reference to certain regular point sets" [5]. This paper was inspired by a paper by M. E. Wise [14] entitled "On the radii of five packed spheres in mutual contact." While working for a Pneumoconiosis Research Unit in Penarth, Wales, Wise had investigated the radii of five spheres in mutual contact, and had discovered the Soddy theorem in three dimensions without knowing about the theorem in two dimensions!

Wise uses inversion, and so does Fog, and as far as this goes both procedures are exactly the same as my own. But Fog then obtains the Soddy theorem in n dimensions by obtaining the polynomial relation which connects the squares of the distances of $n+2$ points in real Euclidean space of n dimensions in the special case when $n+1$ of the points form a regular simplex. Our previous work shows how a regular simplex enters on the scene. Both the Wise and Fog papers are excellent. Let us see how inversion produces the original Soddy theorem in two dimensions without any assumptions about polynomial relations. The proof will illustrate the mechanism underlying the Wise proof for three dimensions.

We have four circles in mutual contact, touching externally, and we are go-

ing to invert the figure, choosing the center of inversion at the point of contact of two of the circles. With this point as origin of coordinates, let the equations of the two circles be

$$(x - 1/\epsilon_1)^2 + y^2 - 1/\epsilon_1^2 = 0,$$

and

$$(x + 1/\epsilon_2)^2 + y^2 - 1/\epsilon_2^2 = 0.$$

Take the circle of inversion as

$$x^2 + y^2 - 1 = 0.$$

The inverse of each circle is merely the chord of intersection with the circle of inversion, so that the inverses are

$$x = \epsilon_1/2 \quad \text{and} \quad x = -\epsilon_2/2,$$

two parallel lines. The remaining two circles invert into two circles which touch these lines and each other. Their centers must lie on the line $x=(\epsilon_1-\epsilon_2)/4=p$, say, and the radius of each of these circles is

$$r = (\epsilon_1 + \epsilon_2)/4.$$

If one of these circles is $(x-p)^2+(y-q)^2-r^2=0$, it is the inverse of the circle

$$x^2 + y^2 - \frac{2(px + qy)}{p^2 + q^2 - r^2} + \frac{1}{(p^2 + q^2 - r^2)^2} = 0,$$

so that

$$\frac{1}{\epsilon_3^2} = \frac{p^2 + q^2}{(p^2 + q^2 - r^2)^2} - \frac{1}{(p^2 + q^2 - r^2)} = \frac{r^2}{(p^2 + q^2 - r^2)^2},$$

and therefore

$$\pm r\epsilon_3 = p^2 + q^2 - r^2.$$

Since $p^2+q^2-r^2=-\epsilon_1\epsilon_2/4+q^2$, we assume that q is sufficiently large for r to be positive. We now have

$$r\epsilon_3 = p^2 + q^2 - r^2, \tag{1}$$

and therefore also

$$r\epsilon_4 = p^2 + (q + 2r)^2 - r^2, \tag{2}$$

since the center of the fourth *inverted* circle is at a distance $2r$ from that of the third inverted circle, touching it externally.

All we have to do now is to eliminate q from (1) and (2) to obtain the Soddy theorem. We note, however, that (1) is merely a statement of what should be a well-known formula in inversion:

$$(R/R')^2 = (D^2 - R^2)^2, \tag{3}$$

which gives the radius R' of the inverse of a circle of radius R in a unit circle, D being the distance of the center of inversion from the center of the circle of radius R. Using this formula, (1) and (2) are obtained immediately.

To eliminate q, subtract (2) from (1), obtaining

$$r(\epsilon_3 - \epsilon_4) = -4qr - 4r^2;$$

substituting for q^2 in (1) gives

$$16(r\epsilon_3 + r^2 - p^2) = 16q^2 = (4r + \epsilon_3 - \epsilon_4)^2;$$

the substitution of $p = (\epsilon_1 - \epsilon_2)/4$ and $r = (\epsilon_1 + \epsilon_2)/4$ in this equation leads directly to the Soddy theorem. This is probably the simplest elementary proof for the case $n = 2$.

For the case $n = 3$, we should find after inversion that we need a relation between the distances of a given point from the vertices of an equilateral triangle of given side, the point being at a given distance from the plane of the triangle, and so on. This is the method of Wise, extended to n dimensions by Fog.

The assertion we have not yet justified is that there exists an algebraic relation between the curvatures of four circles in a plane which touch each other. This is derived immediately from the identical relation which we have already used connecting the lengths d_{ij} of the six joins P_iP_j of the four centers P_i $(i = 1, \cdots, 4)$ if we put

$$d_{ij} = r_i + r_j,$$

assuming the circles all touch each other externally. The identical relation occurs most naturally in determinantal form as

$$\begin{vmatrix} 0 & d_{12}^2 & d_{13}^2 & d_{14}^2 & 1 \\ d_{21}^2 & 0 & d_{23}^2 & d_{24}^2 & 1 \\ d_{31}^2 & d_{32}^2 & 0 & d_{34}^2 & 1 \\ d_{41}^2 & d_{42}^2 & d_{43}^2 & 0 & 1 \end{vmatrix} = 0,$$

(see, for instance, Kowalesky [10], p. 242). By simple manipulation this determinant can be reduced to the form

$$\begin{vmatrix} -1 & 1 & 1 & 1 & \epsilon_1 \\ 1 & -1 & 1 & 1 & \epsilon_2 \\ 1 & 1 & -1 & 1 & \epsilon_3 \\ 1 & 1 & 1 & -1 & \epsilon_4 \\ \epsilon_1 & \epsilon_2 & \epsilon_3 & \epsilon_4 & 0 \end{vmatrix} = 0,$$

where $\epsilon_i = r_i^{-1}$, and the existence of an algebraic relation between the ϵ_i is estab-

lished. Moreover it is clearly a symmetric quadratic form in the ϵ_i. This method extends immediately to the case of $n+2$ spheres in mutual contact in Euclidean space of n dimensions, leading to the relation

$$\begin{vmatrix} -1 & 1 & 1 & \cdots & 1 & \epsilon_1 \\ 1 & -1 & 1 & \cdots & 1 & \epsilon_2 \\ 1 & 1 & -1 & \cdots & 1 & \epsilon_3 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & 1 & 1 & \cdots & -1 & \epsilon_{n+2} \\ \epsilon_1 & \epsilon_2 & \epsilon_3 & \cdots & \epsilon_{n+2} & 0 \end{vmatrix} = 0,$$

and our previous methods show that the expanded form of this determinant is

$$n \sum \epsilon_i^2 - \left(\sum \epsilon_i\right)^2 = 0 \quad (i = 1, \cdots, n+2).$$

This method of showing there is an algebraic relation between the ϵ_i is due to the late Prof. A. Aeppli [1]. His method for obtaining the coefficients in the expansion of the determinant differs from that given above. I am indebted to his son, my colleague Prof. Alfred Aeppli, for drawing my attention to his father's paper, and also to the fact that his father had traced the theorem we have been discussing (for the case $n=2$) back to Descartes! It appears that Descartes had mentioned the theorem in a letter to the Princess Elizabeth (p. 49 of [4]). The theorem was also known to Steiner (p. 63 of Vol. 1 of [13]). Evidently Soddy revived the theorem, and certainly obtained a lot of publicity for it, but this is hardly enough for a lasting claim to be laid to the theorem, and we shall now refer to the two-dimensional case as "The Descartes circle theorem," and to the n-dimensional case as "The extension of the Descartes circle theorem." If the theorem is to be named after everyone who has rediscovered it, we should add the names of Steiner, Wise and others. Perhaps one day a Mathematical Council will meet and decide on such matters!

We now approach the configuration of four circles in mutual contact in a plane from another point of view. We represent the circles by points in Euclidean space of three dimensions, E_3. This representation is fully worked out in my book [11]. We give a few details here since the same representation will be of use in our next look at the Descartes circle theorem, using the Grassmann calculus.

A normalized circle, with coefficient of x^2+y^2 unity,

$$C \equiv x^2 + y^2 - 2\xi x - 2\eta y + \zeta = 0$$

is represented by the point (ξ, η, ζ) in E_3. This gives a mapping, if we use ordinary rectangular cartesian coordinates, with the point (ξ, η, ζ) immediately above the center of the circle, or, less informally, the center of the circle is the orthogonal projection of the representative point onto the (x, y)-plane. Circles

of radius zero (called point-circles) are mapped on the points of the paraboloid of revolution

$$\Omega \equiv z - x^2 - y^2 = 0.$$

Circles of imaginary radius are mapped onto points which lie inside Ω, and are treated equally with ordinary circles, which are mapped onto points outside or on Ω. Circles of the coaxal system $\lambda_1 C_1 + \lambda_2 C_2 = 0$ are mapped onto the points of the line in E_3 which joins the points representing C_1 and C_2. The real limiting points of the coaxal system, if they exist, are given by the orthogonal projection of the points of intersection of this line with Ω. If C_1 and C_2 touch, this line *touches* Ω.

If we erect parallels to the z axis at the points of the circle C, these will intersect Ω in a plane section, of equation

$$z - 2\xi x - 2\eta y + \zeta = 0.$$

This is the *polar plane* of the representative point (ξ, η, ζ) with respect to the quadric Ω. Two points (ξ_1, η_1, ζ_1) and (ξ_2, η_2, ζ_2) are conjugate with regard to Ω, so that

$$2\xi_1\xi_2 + 2\eta_1\eta_2 - \zeta_1 - \zeta_2 = 0$$

if and only if the circles C_1 and C_2 which they represent are *orthogonal.* The point circles on the circumference of C are orthogonal to C. Hence we have a representation of circles by plane sections of Ω, or by points, the *poles* of the plane sections with respect to Ω.

Finally, inversion of circles in a fixed circle C in the plane is represented in E_3 by a *harmonic homology* of the points of E_3, the center of the homology being the point which represents C, and the plane of fixed points being the polar of this point with respect to Ω. The points of Ω which lie in pairs on lines through the center of the harmonic homology are interchanged by the mapping, and project into inverse points in C.

Now, four circles in the plane which touch each other are mapped onto the four vertices of a tetrad in E_3, the sides of which all touch Ω. Harmonic homology applied to such a tetrad produces a tetrad with similar properties in relation to Ω, and there must be some invariant of such a tetrad under a harmonic homology which is the expression of the Descartes theorem for circles in a plane. The discovery of such an invariant would perhaps produce the most satisfactory proof of the Descartes theorem, but, failing this, let us use this theorem to produce a theorem for a tetrad whose six edges all touch a paraboloid of revolution!

We note that if the points A, B of E_3 represent the circles C_1, C_2 of radii ϵ_1^{-1}, ϵ_2^{-1}, which we suppose touch externally at P, then P is the orthogonal projection of the point X on AB where the line AB touches Ω, and we have the simple relation $AX:XB = \epsilon_1^{-1}:\epsilon_2^{-1} = AP:PB$. If we write the Descartes relation as

$$2\left\{1 + \left(\frac{\epsilon_2}{\epsilon_1}\right)^2 + \left(\frac{\epsilon_3}{\epsilon_1}\right)^2 + \left(\frac{\epsilon_4}{\epsilon_1}\right)^2\right\} = \left(1 + \frac{\epsilon_2}{\epsilon_1} + \frac{\epsilon_3}{\epsilon_1} + \frac{\epsilon_4}{\epsilon_1}\right)^2,$$

and A, B, C and D represent the four circles, where AB touches Ω at X, AC touches Ω at Y and AD touches Ω at Z, using the relations $AX:XB=\epsilon_1^{-1}:\epsilon_2^{-1}$, $AY:YC=\epsilon_1^{-1}:\epsilon_3^{-1}$, and $AZ:ZD=\epsilon_1^{-1}:\epsilon_4^{-1}$, we obtain the relation:

$$2\left\{1+\left(\frac{AX}{XB}\right)^2+\left(\frac{AY}{YC}\right)^2+\left(\frac{AZ}{ZD}\right)^2\right\}=\left(1+\frac{AX}{XB}+\frac{AY}{YC}+\frac{AZ}{ZD}\right)^2,$$

connecting the vertices A, B, C, and D and the points of contact X, Y and Z of AB, AC and AD respectively of a tetrad $ABCD$ *all* of whose six edges touch a paraboloid of revolution.

If we had some simple way of proving *this* theorem, the Descartes circle theorem would follow immediately!

Our last look at the Descartes circle theorem is via the Grassmann calculus. The methods of Grassmann were extended and applied to circles by Homersham Cox in 1883 [2], and are given by Forder in his interesting book [6] on the Grassmann calculus. These methods have always smacked of the theologio-mathematical, since higher entities are invoked from time to time, and these can be persuaded to work apparent miracles! But as far as the applications lead to a simple proof of the Descartes theorem, we believe we can explain the calculus in terms of our representation of circles given in the previous section. The same methods will then lead to the generalization of the theorem to n dimensions.

We have seen how circles can be combined linearly, using the mapping:

$$C\equiv x^2+y^2-2\xi x-2\eta y+\zeta=0\rightarrow(\xi,\eta,\zeta).$$

We can also map a circle C on its plane section representation:

$$C\equiv x^2+y^2-2\xi x-2\eta y+\zeta=0\rightarrow z-2\xi x-2\eta y+\zeta=0,$$

and in the present context this is the more convenient mapping. These plane sections can also be combined linearly, but we note that since our circles are normalized, we are essentially using barycentric coordinates in E_3, and we can therefore find *four* linearly independent circles, but any set of five circles is linearly dependent. For instance, although we have not yet mentioned improper circles (of infinite radius), it is clear that the four circles $x=0$, $y=0$, $x^2+y^2-1=0$ and $x^2+y^2+1=0$ are linearly independent, and that any given circle can be expressed linearly in terms of this set of four circles.

There is no difficulty with improper circles. If we consider

$$C_1-C_2\equiv-2(\xi_1-\xi_2)x-2(\eta_1-\eta_2)y+\zeta_1-\zeta_2=0,$$

this line, the radical axis of the two circles, is represented without difficulty by the plane section of Ω which has the same equation, the plane being parallel to the z-axis. The point representation in this case breaks down. But if we consider the radical axis of two concentric circles, both representations break down. If the common center is (ξ_1,η_1),

$$C_1 - C_2 \equiv \zeta_1 - \zeta_2 = 0,$$

and there is no finite plane section representation. But we are accustomed to the paradoxical equation: *constant* $=0$ representing the plane at infinity, and we introduce this special plane section of Ω, and call it θ. We shall normalize it in a moment.

We observe that θ can always be used as one of the plane sections in E_3 which form a linearly dependent set with any given four planes. In other words, given any four circles, there always exists a linear relation between them of the form

$$x_1C_1 + x_2C_2 + x_3C_3 + x_4C_4 = \theta,$$

where θ is merely some definite non-zero constant.

We now introduce an *inner product* for two circles C_1, C_2. We write

$$[C_1 \cdot C_2] = \tfrac{1}{2}(2\xi_1\xi_2 + 2\eta_1\eta_2 - \zeta_1 - \zeta_2).$$

This looks familiar, and of course it arises very naturally from our point of view. Cox introduces it as

$$[C_1 \cdot C_2] = \tfrac{1}{2}\{r_1^2 + r_2^2 - (O_1 - O_2)^2\},$$

where r_1, r_2 are the respective radii, O_1 and O_2 the respective centers of the two circles. This is an equivalent expression (see [11], p. 32).

The inner product is bilinear and commutative. (This is true for normalized circles; some detail has been omitted here.) Hence its usefulness. It is zero for two orthogonal circles, and $[C_1 \cdot C_1]$, which we write C_1^2, is r_1^2 (hence the introduction of the factor 1/2). If C_1, C_2 touch externally

$$[C_1 \cdot C_2] = \tfrac{1}{2}(r_1^2 + r_2^2 - (r_1 + r_2)^2) = -r_1r_2,$$

and if C_1, C_2 are concentric, $[C_1 \cdot C_2] = (r_1^2 + r_2^2)/2$.

We have one more piece of machinery to set up, and then we can prove our theorem and its generalization. We investigate the inner product of θ with proper circles and with itself. If C_1 and C_2 are concentric,

$$C_1 - C_2 = \zeta_1 - \zeta_2 = k\theta,$$

where k has to be determined. This can be written

$$C_1 - C_2 = (\xi_1^2 + \eta_1^2 - \zeta_2) - (\xi_1^2 + \eta_1^2 - \zeta_1)$$

and we choose $k = (r_1^2 - r_2^2)/2$, thus normalizing θ as the constant -2. We now have $C_1 - C_2 = \tfrac{1}{2}(r_1^2 - r_2^2)\theta$. Hence

$$\begin{aligned}[C_1 \cdot (C_1 - C_2)] &= [C_1 \cdot (\tfrac{1}{2}(r_1^2 - r_2^2)\theta)] = C_1^2 - [C_1 \cdot C_2] \\ &= r_1^2 - (r_1^2 + r_2^2)/2 = (r_1^2 - r_2^2)/2.\end{aligned}$$

Since $[C_1\cdot(\frac{1}{2}(r_1^2-r_2^2)\theta)]=\frac{1}{2}(r_1^2-r_2^2)[C_1\cdot\theta]$, we deduce that

$$[C_1\cdot\theta] = 1$$

for any proper circle C_1. Finally, since

$$\begin{aligned}\tfrac{1}{4}(r_1^2 - r_2^2)^2\theta^2 &= [(C_1 - C_2)\cdot(C_1 - C_2)]\\ &= C_1^2 - 2[C_1\cdot C_2] + C_2^2\\ &= r_1^2 - (r_1^2 + r_2^2) + r_2^2 = 0,\end{aligned}$$

we find that $\theta^2=0$.

We reassure ourselves about this result by remembering that θ represents a special plane section of Ω, by the plane at infinity, and this touches Ω at infinity, Ω being a paraboloid, and the point of contact, being on Ω, represents a zero circle, so that $C_1^2=r_1^2$ would lead us to expect that $\theta^2=0$. But we could hardly have proved the property this way!

If we weight our circles in advance by multiplying each of them by its curvature, the reciprocal of its radius, then two circles C_1, C_2 touching externally, have the inner product $[C_1\cdot C_2]=-1$ (instead of $-r_1r_2$), and $[C_1\cdot\theta]=1/r_1$ (instead of 1).

We can now prove the Descartes circle theorem. Take four weighted circles of curvatures ϵ_i $(i=1, \cdots, 4)$ which touch each other externally. We can write, the weighted circles being C_i $(i=1, \cdots, 4)$,

$$x_1C_1 + x_2C_2 + x_3C_3 + x_4C_4 = \theta.$$

Forming the inner product of both sides with C_1, we have

$$x_1C_1^2 + x_2[C_1\cdot C_2] + x_3[C_1\cdot C_3] + x_4[C_1\cdot C_4] = [C_1\cdot\theta],$$

that is $x_1-x_2-x_3-x_4=\epsilon_1$. Similarly we obtain three more equations:

$$\begin{aligned}-x_1 + x_2 - x_3 - x_4 &= \epsilon_2,\\ -x_1 - x_2 + x_3 - x_4 &= \epsilon_3,\\ -x_1 - x_2 - x_3 + x_4 &= \epsilon_4.\end{aligned}$$

We now form the inner product with θ, and we obtain

$$\epsilon_1x_1 + \epsilon_2x_2 + \epsilon_3x_3 + \epsilon_4x_4 = 0.$$

From the first four equations we find that

$$\sum \epsilon_i^2 = 4\sum x_i^2, \quad \text{and} \quad \sum \epsilon_i\epsilon_j = 4\sum x_ix_j.$$

But, substituting for the ϵ_i from the first four equations in the last we find that

$$\sum x_i^2 - 2\sum x_ix_j = 0,$$

so that we have

$$\sum \epsilon_i^2 - 2 \sum \epsilon_i \epsilon_j = 0 \quad (1 \leqq i < j \leqq 4),$$

and this is the Descartes circle theorem.

The method of representing circles by points in E_3 can evidently be extended to the representation of spheres in E_n by points in E_{n+1}. The details correspond exactly, and we can at once say that if we have $n+2$ weighted spheres touching each other externally in E_n, we can write

$$x_1 C_1 + x_2 C_2 + \cdots + x_{n+2} C_{n+2} = \theta,$$

and forming the inner products we have a set of equations

$$\begin{aligned} x_1 - x_2 - \cdots - x_{n+2} &= \epsilon_1, \\ \cdots\cdots\cdots\cdots\cdots\cdots & \\ -x_1 - x_2 - \cdots + x_{n+2} &= \epsilon_{n+2}, \end{aligned}$$

and the equation

$$\epsilon_1 x_1 + \epsilon_2 x_2 + \cdots + \epsilon_{n+2} x_{n+2} = 0.$$

The subsequent procedures are the same; merely the coefficients are different. We obtain

$$\sum \epsilon_i^2 = (n+2) \sum x_i^2 + (2n-4) \sum x_i x_j,$$

$$\sum \epsilon_i \epsilon_j = (n+1)(\tfrac{1}{2}n - 1) \sum x_i^2 + (2n+2) \sum x_i x_j,$$

from the first set of equations, and substituting in the final equation for the ϵ_i gives again

$$\sum x_i^2 - 2 \sum x_i x_j = 0,$$

so that now we have

$$(n-1) \sum \epsilon_i^2 - 2 \sum \epsilon_i \epsilon_j = 2n \sum x_i^2 - 4n \sum x_i x_j = 2n\left(\sum x_i^2 - 2 \sum x_i x_j \right) = 0,$$

so that the Descartes theorem in n dimensions is

$$n \sum \epsilon_i^2 = \left(\sum \epsilon_i \right)^2, \qquad (i = 1, \cdots, n+2).$$

In conclusion, it may be said of geometry, as has been said of other more popular and less abstract entities, that it is a many-splendoured thing. In fact, since geometry is not at all easy to define, we might hazard the definition that any part of mathematics which can be regarded interestingly from more than one point of view qualifies to be regarded as geometry!

MATRICES WITH SPECIFIED EIGENVALUES AND ASSOCIATED EIGENVECTORS, PROPER OR GENERALIZED

LOUIS BRAND, University of Houston

1. Introduction. We shall consider $n \times n$ matrices with elements in the field of reals and limit our discussion to the case when all eigenvalues are real. If λ_i is an eigenvalue and e_i an associated *proper eigenvector*, $Ae_i = \lambda_i e_i$ or

$$(A - \lambda_i I)e_i = 0. \tag{1}$$

We shall regard all members of the equivalence class formed by the scalar multiples of e_i as the same eigenvector.

For a multiple eigenvalue λ_1 various cases arise which depend on the rank of the matrix $A - \lambda_1 I$. If λ_1 is k-tuple and $\operatorname{rank}(A - \lambda_1 I) = n - 1$, there will be a single proper eigenvector e_1 that satisfies (1) and $k-1$ *generalized eigenvectors* $e_2, e_3, \cdots, e_k$ which satisfy the $k-1$ equations

$$(A - \lambda_1 I)e_i = e_{i-1}, \qquad i = 2, 3, \cdots, k. \tag{2}$$

We shall show that these equations are consistent, obtain explicit expressions for $e_1, e_2, \cdots, e_k$, and show that these vectors are linearly independent.

When λ_1 is k-tuple and $\operatorname{rank}(A - \lambda_1 I) = n - m$, there are m proper and $k - m$ generalized eigenvectors which belong to λ_1. In the extreme case when rank

$(A-\lambda_1 I)=0$, $A=\lambda_1 I$ and any n linearly independent vectors of n-space are proper eigenvectors.

We shall first describe a procedure for computing eigenvectors which is a generalization of the method used for the companion matrix [1].

2. Computation of Eigenvectors. The eigenvalues λ_i of a matrix A are the zeros of the function

$$f(\lambda) = \det(A - \lambda I). \tag{3}$$

If λ is not an eigenvalue, $f(\lambda)\neq 0$ and the equation

$$(A - \lambda I)e(\lambda) = [f(\lambda), 0, \cdots, 0]^{\mathsf{T}} \tag{4.1}$$

has a unique column vector $e(\lambda)$ as solution whose components are *polynomials* in λ. We shall omit the transpose symbol T and denote a column by a row in square brackets. If the eigenvalues are all simple, a single eigenvector belongs to each eigenvalue and is given by $e(\lambda_i)$ provided $e(\lambda_i)\neq 0$; for when $\lambda=\lambda_i$, equation (4.1) reduces to (1).

If $f(\lambda)$ is chosen as the jth component (instead of the first) the equation is numbered as (4.j). All of the n equations (4.1) to (4.n) will yield the same eigenvector $e(\lambda_i)$ when λ_i is a simple zero provided $e(\lambda_i)\neq 0$. The computation is shown in Example 1.

If λ_1 is a k-tuple zero of $f(\lambda)$ and rank $(A-\lambda_1 I)=n-1$, then there is one proper eigenvector e_1 and $k-1$ generalized eigenvectors $e_2, e_3, \cdots, e_k$. These satisfy equation (4.1) and the $k-1$ equations obtained from it by differentiating $k-1$ times with respect to λ and then putting $\lambda=\lambda_i$. From (4.1) we have

$$\begin{aligned}
(A - \lambda I)e'(\lambda) - e(\lambda) &= [f'(\lambda), 0, \cdots, 0] \\
(A - \lambda I)e''(\lambda) - 2e'(\lambda) &= [f''(\lambda), 0, \cdots, 0] \\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\
(A - \lambda I)e^{k-1}(\lambda) - (k-1)e^{k-2}(\lambda) &= [f^{(k-1)}(\lambda), 0, \cdots, 0].
\end{aligned} \tag{5}$$

Since λ_i is a k-tuple zero of $f(\lambda)$, all vectors on the right vanish when $\lambda=\lambda_i$ and yield the system

$$\begin{aligned}
(A - \lambda_i I)e'(\lambda_i) &= e(\lambda_i) \\
(A - \lambda_i I)\tfrac{1}{2}e''(\lambda_i) &= e'(\lambda_i) \\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\
(A - \lambda_i I)\frac{1}{(k-1)!}e^{k-1}(\lambda_i) &= \frac{1}{(k-2)!}e^{k-2}(\lambda_i).
\end{aligned} \tag{6}$$

A comparison with equation (2) now reveals that a set of generalized eigenvectors belonging to λ_i is given by

$$e_j = \frac{1}{(j-1)!}e^{j-1}(\lambda_i), \qquad j = 2, 3, \cdots, k. \tag{7}$$

The existence of this solution shows that equations (2) are consistent. The computation is illustrated in Example 2.

The linear independence of the set of eigenvectors may be shown by assuming the linear relation

$$c_1e_1 + c_2e_2 + \cdots + c_ke_k = 0$$

and premultiplying it $k-1$ times by the matrix $(A-\lambda_iI)$. We then find in turn that

$$\begin{aligned} &c_2e_1 + c_3e_2 + \cdots + c_ke_{k-1} = 0 \\ &\cdots\cdots\cdots\cdots\cdots \\ &c_{k-1}e_1 + c_ke_2 = 0 \\ &c_ke_1 = 0. \end{aligned}$$

Since $e_1 \neq 0$, $c_k = 0$; and on passing upward through these equations we find that all the constants $c_i = 0$.

When $\operatorname{rank}(A-\lambda_1 I) = n-m (m>1)$, the computation of m proper and $k-m$ generalized eigenvectors for k-tuple λ_1 is illustrated in Examples 2 and 4.

The author believes that the foregoing procedure yields all the eigenvectors, proper and generalized, but realizes that a strict proof cannot rest on examples, however diverse.

Example 1. For the symmetric matrix

$$A = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \qquad f(\lambda) = -(\lambda-1)(\lambda+1)(\lambda-2)$$

and 1, -1, 2 are the eigenvalues. Equation (4.1) becomes

$$\begin{bmatrix} 1-\lambda & 1 & 0 \\ 1 & -\lambda & 1 \\ 0 & 1 & 1-\lambda \end{bmatrix} e(\lambda) = \begin{bmatrix} f(\lambda) \\ 0 \\ 0 \end{bmatrix};$$

it has the unique solution

$$e(\lambda) = [\lambda^2 - \lambda - 1, \lambda - 1, 1]$$

and the mutually orthogonal eigenvectors are

$$e(1) = [-1, 0, 1], \qquad e(-1) = [1, -2, 1], \qquad e(2) = [1, 1, 1].$$

Equation (4.3) yields $e(\lambda) = (1, \lambda-1, \lambda^2-\lambda-1)$ and gives the same results. But (4.2) gives

$$e(\lambda) = (\lambda-1)[1, \lambda-1, 1],$$

$$e(1) = [0, 0, 0], \qquad e(-1) = [-2, 4, -2], \qquad e(2) = [1, 1, 1].$$

We cannot divide out $\lambda-1$ and then put $\lambda=1$ for $f(\lambda)/(\lambda-1)\neq 0$ when $\lambda=1$. See Example 3, in which this division is permissible.

Example 2. For the matrix

$$A=\begin{bmatrix} 3 & 2 & -1 \\ -3 & -2 & 2 \\ -1 & -1 & 2 \end{bmatrix}, \qquad f(\lambda) = -(\lambda-1)^3$$

and 1 is a triple eigenvalue. Equation (4.1),

$$\begin{bmatrix} 3-\lambda & 2 & -1 \\ -3 & -2-\lambda & 2 \\ -1 & -1 & 2-\lambda \end{bmatrix} e(\lambda) = \begin{bmatrix} f(\lambda) \\ 0 \\ 0 \end{bmatrix}$$

has the unique solution $e(\lambda)=[\lambda^2-2,\ 4-3\lambda,\ 1-\lambda]$. Since $\operatorname{rank}(A-I)=2$, this yields the only proper eigenvector $e_1=e(1)=(-1,\ 1,\ 0)$. The two generalized eigenvectors are

$$e_2 = e'(1) = (2, -3, -1),$$
$$e_3 = \tfrac{1}{2}e''(1) = (1, 0, 0).$$

Example 3. For the matrix

$$A=\begin{bmatrix} -1 & 2 & -2 \\ 4 & -3 & 4 \\ 4 & -4 & 5 \end{bmatrix}, \qquad f(\lambda) = -(\lambda+1)(\lambda-1)^2,$$

and -1, 1, 1 are the eigenvalues. Equation (4.1)

$$\begin{bmatrix} -1-\lambda & 2 & -2 \\ 4 & -3-\lambda & 4 \\ 4 & -4 & 5-\lambda \end{bmatrix} e(\lambda) = \begin{bmatrix} f(\lambda) \\ 0 \\ 0 \end{bmatrix}$$

has the unique solution

$$e(\lambda) = (\lambda-1)[\lambda-1, 4, 4].$$

Moreover $E(\lambda)=e(\lambda)/(\lambda-1)=[\lambda-1,\ 4,\ 4]$ satisfies

$$(A-\lambda I)E(\lambda) = [1-\lambda^2, 0, 0]$$

and yields the proper eigenvectors

$$E(1) = 4[0, 1, 1], \qquad E(-1) = 2[-1, 2, 2].$$

Since $\operatorname{rank}(A-I)=1$, a 2-space of proper eigenvectors belongs to 1. One is given by equation (4.2), namely

$$E(\lambda) = \frac{e(\lambda)}{\lambda-1} = [2, \lambda-3, -4];$$

hence

$$E(1) = -2[-1, 1, 2], \qquad E(-1) = -2[-1, 2, 2].$$

All vectors in the space spanned by $[0, 1, 1]$ and $[-1, 1, 2]$ are eigenvectors for $\lambda = 1$. Another such vector is given by equation (4.3):

$$E(\lambda) = \frac{e(\lambda)}{\lambda - 1} = [-2, 4, \lambda + 5];$$

$$E(1) = 2[-1, 2, 3], \qquad E(-1) = 2[-1, 2, 2].$$

Example 4. For the matrix

$$A = \begin{bmatrix} 9 & 2 & -6 \\ 4 & 2 & -3 \\ 12 & 3 & -8 \end{bmatrix}, \qquad f(\lambda) = (1 - \lambda)^3,$$

and 1 is a triple eigenvalue. Equations (4.1), (4.2) and (4.3) yield respectively

$$e_1(\lambda) = (\lambda - 1)[\lambda + 7, 4, 12], \qquad E_1(\lambda) = [\lambda + 7, 4, 12];$$
$$e_2(\lambda) = (\lambda - 1)[2, \lambda, 3], \qquad E_2(\lambda) = [2, \lambda, 3];$$
$$e_3(\lambda) = (\lambda - 1)[6, 3, 10 - \lambda], \qquad E_3(\lambda) = [6, 3, 10 - \lambda].$$

When $\lambda = 1$, all give the same proper eigenvector:

$$E_1(1) = 4[2, 1, 3], \qquad E_2(1) = [2, 1, 3], \qquad E_3(1) = 3[2, 1, 3].$$

But since rank $(A - I) = 1$, there *must* be a second proper eigenvector e_3 and a generalized eigenvector $e_2 = e_1'$ corresponding to $e_1 = [2, 1, 3]$ which is given by

$$\tfrac{1}{4}E_1' = [\tfrac{1}{4}, 0, 0] = e_{21},$$

or $E_2' = [0, 1, 0] = e_{22}$, or $\tfrac{1}{3}E_3' = [0, 0, -\tfrac{1}{3}] = e_{23}$.

Since a generalized eigenvector satisfies (2), we have

$$(A - \lambda_1 I)e_{21} = e_1, \qquad (A - \lambda_1 I)e_{22} = e_1, \qquad (A - \lambda_1 I)(e_{21} - e_{22}) = 0,$$

that is, $e_{21} - e_{22}$ is a proper eigenvector. Thus we have three new proper eigenvectors

$$e_{21} - e_{22} = [\tfrac{1}{4}, -1, 0] = \tfrac{1}{4}[1, -4, 0],$$

$$e_{21} - e_{23} = [\tfrac{1}{4}, 0, \tfrac{1}{3}] = \tfrac{1}{12}[3, 0, 4],$$

$$e_{22} - e_{23} = [0, 1, \tfrac{1}{3}] = \tfrac{1}{3}[0, 3, 1].$$

Thus any of the vectors $[1, -4, 0]$, $[3, 0, 4]$, $[0, 3, 1]$ may be chosen for e_3 and all three lie in a plane with e_1.

The generalized eigenvector corresponding to $e_1 = [2, 1, 3]$ is most simply chosen as $e_2 = [0, 1, 0]$.

Example 5. When $A = I$, the unit matrix of order 3, $f(\lambda) = (1-\lambda)^3$ and equations (4.1), (4.2), (4.3) yield in turn, after rejecting the factor $(1-\lambda)^2$ since $1-\lambda$ still remains on the right,

$$e_1 = [1, 0, 0], \qquad e_2 = [0, 1, 0], \qquad e_3 = [0, 0, 1].$$

Since $\operatorname{rank}(A - I) = 0$, all vectors in the 3-space spanned by e_1, e_2, e_3 are proper eigenvectors.

3. Reduction to a Jordan Matrix. From the eigenvectors of a matrix, arranged in groups according to the distinct eigenvalues, we form the matrix

$$E = (e_1 | e_2 | \cdots | e_n) \tag{8}$$

having e_i as *columns*. Since the vectors e_i are linearly independent, they admit a reciprocal set $e^1, e^2, \cdots, e^n$ for which

$$e_i \cdot e^j = \delta_i^j, \qquad i, j = 1, 2, \cdots, n. \tag{9}$$

These equations show that the matrix having e^j as *rows* is the inverse of E:

$$E^{-1} = \begin{pmatrix} e^1 \\ \hline e^2 \\ \hline \cdot \\ \cdot \\ \hline e^n \end{pmatrix} \tag{10}$$

Then the product

$$E^{-1}AE = J \tag{11}$$

is the Jordan matrix for A corresponding to the grouping of eigenvectors in (8). The proof is immediate and is a direct consequence of equations (1), (2) and (9).

Thus in Example 1 ($\lambda_1 = 1$, $\lambda_2 = -1$, $\lambda_3 = 2$)

$$E^{-1}AE = \begin{pmatrix} e^1 \\ \hline e^2 \\ \hline e^3 \end{pmatrix} (e_1 | -e_2 | 2e_3) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix}.$$

In Example 2 ($\lambda_1 = \lambda_2 = \lambda_3 = 1$)

$$E^{-1}AE = \begin{pmatrix} e^1 \\ \hline e^2 \\ \hline e^3 \end{pmatrix} (e_1 | e_2 + e_1 | e_3 + e_2) = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

In Example 3 ($\lambda_1=-1$, $\lambda_2=\lambda_3=1$)

$$E^{-1}AE=\left(\begin{array}{c}e^1\\ \hline e^2\\ \hline e^3\end{array}\right)(-e_1\,|\,e_2\,|\,e_3+e_2)=\begin{pmatrix}-1&0&0\\0&1&1\\0&0&1\end{pmatrix}.$$

In Example 4 ($\lambda_1=\lambda_2=\lambda_3=1$) when e_3 is referred to e_1

$$E^{-1}AE=\left(\begin{array}{c}e^1\\ \hline e^2\\ \hline e^3\end{array}\right)(e_1\,|\,e_2+e_1\,|\,e_3)=\begin{pmatrix}1&1&0\\0&1&0\\0&0&1\end{pmatrix};$$

and when e_3 is referred to e_2

$$E^{-1}AE=\left(\begin{array}{c}e^1\\ \hline e^2\\ \hline e^3\end{array}\right)(e_1\,|\,e_2\,|\,e_3+e_2)=\begin{pmatrix}1&0&0\\0&1&1\\0&0&1\end{pmatrix}.$$

4. Matrix with specified eigenvalues and eigenvectors. Let an arbitrary set of linearly independent vectors e_i be chosen and assigned to arbitrary eigenvalues λ_i singly or in groups. In each group specify which vectors are to be proper and which generalized eigenvectors, and refer each generalized eigenvector to its proper companion. For each specific order and grouping we can construct a matrix A which has the eigenvalues and eigenvectors thus specified. This is rather surprising since the generalized eigenvectors must conform to equations (2). To achieve this result, let J be the Jordan matrix which corresponds to the order and grouping of the eigenvalues with due regard to the reference of generalized to proper eigenvectors. Then the required matrix A may be obtained at once from equation (11):

$$A = EJE^{-1}, \tag{12}$$

where E has its columns formed by the specified eigenvectors in the order corresponding to J. We note again that each generalized eigenvector must be referred to its proper companion. To be specific, if the proper e_1 has the generalized e_2 and e_3 referred to it, we write $e_2=e_1'$, $e_3=e_1''$.

Problem. Find a matrix A with the eigenvalues and eigenvectors

$$\begin{aligned}\lambda_1&=1, & e_1&=(2,0,-1,1)\\ \lambda_2&=1, & e_2&=(-1,1,1,1)=e_1'\\ \lambda_3&=1, & e_3&=(1,1,1,1)\\ \lambda_4&=2, & e_4&=(2,0,1,0),\end{aligned}$$

corresponding to this order.

We have

$$E = \begin{pmatrix} 2 & -1 & 1 & 2 \\ 0 & 1 & 1 & 0 \\ -1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}, \qquad E^{-1} = \frac{1}{2}\begin{pmatrix} 0 & -2 & 0 & 2 \\ -1 & -5 & 2 & 4 \\ 1 & 7 & -2 & -4 \\ 0 & -4 & 2 & 2 \end{pmatrix}$$

$$J = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}, \qquad A = EJE^{-1} = \frac{1}{2}\begin{pmatrix} 0 & -18 & 8 & 12 \\ 0 & 2 & 0 & 0 \\ 1 & 1 & 2 & -2 \\ -1 & -5 & 2 & 6 \end{pmatrix}.$$

If we require a matrix B in which e_2 is proper and $e_3 = e_2'$ is referred to e_2,

$$J = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \qquad B = \frac{1}{2}\begin{pmatrix} 1 & -15 & 6 & 8 \\ 1 & 9 & -2 & -4 \\ 1 & 3 & 2 & -2 \\ 1 & 7 & -2 & -2 \end{pmatrix}.$$

5. The inverse matrix. When the company *Matrices to Order* is organized its promotion literature might contain this incentive: "If cash is sent with order we will supply the inverse of the desired matrix free of charge." Indeed this may be done with but slight additional labor; for from (12) we have

$$A^{-1} = EJ^{-1}E^{-1}. \tag{13}$$

Since J is a quasi-diagonal matrix, J^{-1} is also quasi-diagonal with the reciprocals of the original Jordan blocks in its main diagonal. For each block such as

$$J_i = \begin{pmatrix} \lambda & 1 & 0 & 0 \\ 0 & \lambda & 1 & 0 \\ 0 & 0 & \lambda & 1 \\ 0 & 0 & 0 & \lambda \end{pmatrix}, \qquad J_i^{-1} = \begin{pmatrix} \lambda^{-1} & -\lambda^{-2} & \lambda^{-3} & -\lambda^{-4} \\ 0 & \lambda^{-1} & -\lambda^{-2} & \lambda^{-3} \\ 0 & 0 & \lambda^{-1} & -\lambda^{-2} \\ 0 & 0 & 0 & \lambda^{-1} \end{pmatrix}.$$

Thus for the foregoing problem giving A,

$$J^{-1} = \begin{pmatrix} 1 & -1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \frac{1}{2} \end{pmatrix}, \qquad A^{-1} = \frac{1}{2}\begin{pmatrix} 4 & 14 & -6 & -10 \\ 0 & 2 & 0 & 0 \\ -1 & 3 & 3 & 3 \\ 1 & 5 & -2 & -2 \end{pmatrix}.$$

6. An Application. The beautiful theorem of Gantmacher-Krein [2] states that a *totally positive* $n \times n$ matrix (whose minors of *all* orders are positive) has always n distinct positive eigenvalues

$$\lambda_1 > \lambda_2 > \cdots > \lambda_n > 0,$$

and that the associated eigenvectors $e_1, e_2, \cdots, e_n$ have components with exactly $0, 1, 2, \cdots, n-1$ variations in sign.

Is it necessary for a matrix to be totally positive to have this property?

Let us construct a matrix A with

$$\lambda_1 = 3, \quad e_1 = (1, 1, 1)$$
$$\lambda_2 = 2, \quad e_2 = (1, -1, -1); \qquad \text{then } E = \begin{pmatrix} 1 & 1 & 1 \\ 1 & -1 & -1 \\ 1 & -1 & 1 \end{pmatrix}$$
$$\lambda_3 = 1, \quad e_3 = (1, -1, 1)$$

and

$$A = EJE^{-1} = \frac{1}{2}\begin{pmatrix} 1 & 1 & 1 \\ 1 & -1 & -1 \\ 1 & -1 & 1 \end{pmatrix}\begin{pmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & -1 \\ 0 & -1 & 1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} 5 & 2 & -1 \\ 1 & 4 & 1 \\ 1 & 2 & 3 \end{pmatrix}$$

which is not totally positive. This sufficient condition for the stated property is therefore not necessary.

This paper was presented in part at the annual meeting of the Texas section of the MAA at Fort Worth, April 9, 1965.

THE MAXIMAL THEOREMS OF HARDY AND LITTLEWOOD

KEITH PHILLIPS, University of Washington and California Institute of Technology

1. Introduction. In this paper we give a unified treatment of the famous maximal theorems of Hardy and Littlewood. Roughly speaking, these theorems give estimates of the maximal value of the difference quotient of an indefinite integral. They were originally proved by Hardy and Littlewood in 1930 [5]. They have had numerous applications, and in fact were proved in order to solve certain problems in complex function theory. Other applications appear in [9] (e.g., to conjugate functions, or Hilbert transforms), [1] and [8] (to ergodic theory), [7] (to harmonic functions), and [2] (to singular integrals). We are not concerned in this paper with applications, but with presenting the main facts and methods associated with maximal functions. Subsection (3.6) is of secondary interest, and can be skipped. Section 4 is not required for Section 5.

We begin by establishing notation. First, f will denote a nonnegative, extended real-valued, Lebesgue measurable function on R (the real numbers) such that $\int_F f d\lambda < \infty$ for all compact sets F; λ is Lebesgue measure for R. (Later, in sect. 5, f will be defined on R^m). Define three "maximal functions" of f as follows:

$$M_r f(x) = \sup\left\{\frac{1}{\lambda(I)}\int_I f d\lambda\colon I = [x, u],\ x < u < \infty\right\}$$

$$M_l f(x) = \sup\left\{\frac{1}{\lambda(I)}\int_I f d\lambda\colon I = [u, x],\ -\infty < u < x\right\} \tag{1.1}$$

$$Mf(x) = \sup\left\{\frac{1}{\lambda(I)}\int_I f d\lambda\colon I \text{ is a closed interval containing } x\right\}.$$

Thus $M_r f(x)$, $M_l f(x)$, and $Mf(x)$ are three different maximal averages of the function f. All of the maximal theorems are inequalities giving bounds for the integral of one of the maximal functions composed with a monotonic function. As a result, the mappings M_r, M_l, and M carry certain function spaces to others. Notice that the suprema defining our maximal functions are over finite intervals of all possible lengths. By the continuity of the indefinite integrals involved, each of the maximal functions is lower semicontinuous (and hence Borel measurable). The inequalities $f \leqq M_j f \leqq Mf (j = r, l)$ are immediate, but much more is true.

(1.2) THEOREM. *The equality* $Mf = \mathrm{Max}(M_r f, M_l f)$ *holds.*

Proof. Fix x. For $u < x < t$, let

$$A(t) = (t - x)^{-1}\int_x^t f d\lambda \quad \text{and} \quad B(u) = (x - u)^{-1}\int_u^x f d\lambda; \qquad A(x) = B(x) = 0.$$

Let $p_1(u, t) = (t-x)(t-u)^{-1}$, $p_2(u, t) = (x-u)(t-u)^{-1}$, and $C = p_1 A + p_2 B$, for $u \leqq x \leqq t$ and $u \neq t$; then

$$Mf(x) = \sup\{C(u, t)\colon u \leqq x \leqq t,\ t \neq u\}.$$

Let $(u_n, t_n)_{n=1}^{\infty}$ be such that $\lim_{n\to\infty} C(u_n, t_n) = Mf(x)$. The sequence $(p_1(u_n, t_n), p_2(u_n, t_n))_{n=1}^{\infty}$ is contained in the compact subset $[0, 1] \times [0, 1]$ of the plane, and so has a convergent subsequence. Hence there is a sequence $(u_k, t_k)_{k=1}^{\infty}$ such that

$$\lim_{k\to\infty} C(u_k, t_k) = Mf(x) \quad \text{and} \quad \lim_{k\to\infty} (p_1(u_k, t_k), p_2(u_k, t_k)) = (a, b),$$

where $a + b = 1$. For each k, the inequality

$$p_1(u_k, t_k)\, A(t_k) + p_2(u_k, t_k) B(u_k) \leqq p_1(u_k, t_k) M_r f(x) + p_2(u_k, t_k) M_l f(x)$$

holds; hence the inequality

$$Mf(x) \leqq a M_r f(x) + b M_l f(x)$$

holds. Since $a + b = 1$, the inequality $Mf(x) \leqq \mathrm{Max}(M_r f(x), M_l f(x))$ follows. The reverse inequality is immediate from the definitions (1.1). ∎

2. Two fundamental lemmas. The heart of our proofs of the maximal theorems is in the following two lemmas. The lemmas themselves give precise infor-

mation about the size of the maximal functions. For a positive real number t and an extended real-valued nonnegative function g on R, we let

$$E_t[g] = \{x \in R: g(x) > t\}.$$

(2.1) LEMMA. *The equalities*

$$\text{(i)} \qquad \lambda(E_t[M_j f]) = \frac{1}{t}\int_{E_t[M_j f]} f d\lambda \qquad (j = r, l)$$

and the inequality

$$\text{(ii)} \qquad \lambda(E_t[Mf]) \leqq \frac{2}{t}\int_{E_t[Mf]} f d\lambda$$

hold for every $t>0$.

Proof. We prove (i) with $j=r$, the case $j=l$ being almost the same. It is easy to see that $E_t[M_r f]$ is open. Let $\{]\beta_k, \gamma_k[\}_{k=1}^{\infty}$ be the unique pairwise disjoint intervals with union $E_t[M_r f]$. Consider an interval $]\beta_k, \gamma_k[$ (which may of course be infinite). For each $x \in]\beta_k, \gamma_k[$, the set

$$N_x = \left\{s: \int_x^s f d\lambda > t(s-x),\ s \in]x, \gamma_k] \cap R\right\}$$

is nonvoid. This is trivial if $\gamma_k = \infty$. If $\gamma_k < \infty$ and $N_x = \varnothing$, there would be a $w > \gamma_k$ such that $\int_x^w f d\lambda > t(w-x)$. We would have

$$\int_{\gamma_k}^{w} f d\lambda = \int_x^w f d\lambda - \int_x^{\gamma_k} f d\lambda > t(w - \gamma_k),$$

a contradiction since $\gamma_k \notin E_t[M_r f]$. Let $\gamma = \sup N_x$. If $\gamma < \gamma_k$, then the equality $\int_x^y f d\lambda = t(\gamma - x)$ must hold; an obvious argument proves this. Therefore (since N_γ is nonvoid) there is a $y \in]\gamma, \gamma_k] \cap R$ such that $\int_\gamma^y f d\lambda > t(y-\gamma)$. It follows that $\int_x^\gamma f d\lambda > t(y-x)$, a contradiction since $y > \gamma$. We thus have $\gamma_k = \sup N_x$, and hence the inequality $\int_x^{\gamma_k} f d\lambda \geqq t(\gamma_k - x)$ holds for all $x \in]\beta_k, \gamma_k[$; letting $x \to \beta_k$, we get

$$\text{(1)} \qquad \int_{\beta_k}^{\gamma_k} f d\lambda \geqq t(\gamma_k - \beta_k).$$

If $]\beta_k, \gamma_k[$ is infinite, the equality (i) follows. If $]\beta_k, \gamma_k[$ is finite, then the reverse inequality in (1) is immediate ($\beta_k \notin E_t[M_r f]$). Hence in all cases equality holds in (1), and so (i) is proved for $j=r$.

To prove (ii), note that Theorem (1.2) implies that $E_t[Mf] = E_t[M_l f] \cup E_t[M_r f]$. Hence, using (i), we have

$$\lambda(E_t[Mf]) \leqq \lambda(E_t[M_r f]) + \lambda(E_t[M_l f]) \leqq \frac{2}{t}\int_{E_t[Mf]} f d\lambda. \quad \blacksquare$$

(2.2) LEMMA. *For every* $k\in]0, 1[$ *and every* $t>0$, *the following inequalities hold*:

(i) $$\lambda(E_t[M_jf]) \leqq \frac{1}{(1-k)t}\int_{E_{kt}[f]} f d\lambda \qquad (j = r, l);$$

(ii) $$\lambda(E_t[Mf]) \leqq \frac{2}{(1-k)t}\int_{E_{kt}[f]} f d\lambda.$$

Proof. Let

$$g(x) = \begin{cases} f(x) & \text{if } f(x) > kt \\ 0 & \text{otherwise.} \end{cases}$$

Then we have $M_rf \leqq M_rg + kt$, and $E_t[M_rf] \subset E_{(1-k)t}[M_rg]$. Applying (2.1.i), we obtain

(1) $$\lambda(E_t[M_rf]) \leqq \frac{1}{(1-k)t}\int_{E_{(1-k)t}[M_rf]} g d\lambda.$$

Since $g=0$ on $E_{kt}[f]'$, the integral in (1) is less than $\int_{E_{kt}[f]} f d\lambda$.

It is clear how to obtain (i) for $j=l$, and also how to use (2.1.ii) to prove (ii). ∎

Our proof of (2.1.i) is a variant of one of F. Riesz [6]. Lemma (2.2) appears in [4]; the method of proof is due to Wiener [8].

3. $\mathfrak{L}_p$ maximal theorems. For a Lebesgue measurable function g (defined on R) and a positive real number p, we let $\|g\|_p = [\int_R |g|^p d\lambda]^{1/p}$. The function space $\mathfrak{L}_p$ is all g's such that $\|g\|_p < \infty$. The following lemma, an easy application of Fubini's theorem, will be useful. We use the symbol ξ for characteristic functions.

(3.1) LEMMA. *Let* χ *be a function on* $[0, \infty[$ *that is absolutely continuous on every finite interval, and satisfies* $\chi(0)=0$. *For every nonnegative Lebesgue measurable function* g *on* R *and every Lebesgue measurable set* E, *the equality*

$$\int_E (\chi \circ g) d\lambda = \int_0^\infty \chi'(t)\lambda(E \cap E_t[g]) dt$$

holds.

Proof. Write

$$\int_E \chi \circ g \, d\lambda = \int_R \xi_E(x) \int_0^{g(x)} \chi'(t) dt dx$$

$$= \int_0^\infty \int_R \xi_{E \cap E_t[g]}(x) \chi'(t) dx dt = \int_0^\infty \chi'(t)\lambda(E \cap E_t[g]) dt;$$

the use of Fubini's theorem is justified since the set $\{(x, t): x \in E \text{ and } g(x) > t\}$ is product measurable. ∎

(3.2) THEOREM. *For $p > 1$ and $f \in \mathfrak{L}_p$, the inequalities*

(i) $$\|M_j f\|_p \leqq \frac{p}{p-1}\|f\|_p \qquad (j = r, l)$$

and

(ii) $$\|Mf\|_p \leqq \frac{2^{1/p}p}{p-1}\|f\|_p$$

hold.

Proof. The following calculation (using (3.1), (2.2.i), and Fubini's theorem) shows that $M_j f \in \mathfrak{L}_p$:

$$\begin{aligned}\int_R (M_j f)^p d\lambda &= p\int_0^\infty \lambda(E_t[M_j f])t^{p-1}dt \leqq \frac{p}{1-k}\int_0^\infty t^{p-2}\int_{E_{kt}[f]} f d\lambda dt \\ &= \frac{p}{1-k}\int_R f(x)\int_0^\infty \xi_{E_{kt}[f]}(x)t^{p-2}dtdx \\ &= \frac{p}{(p-1)(1-k)k^{p-1}}\int_R f(x)^p dx.\end{aligned}$$

The constant k satisfies $0 < k < 1$. The application of Fubini's theorem is justified because the set $\{(x, t): f(x) > kt\}$ is product measurable. To obtain (i), we use (2.1.i), Fubini's theorem, and Hölder's inequality to calculate as follows:

$$\begin{aligned}\int_R (M_j f)^p d\lambda &= p\int_0^\infty t^{p-2}\int_{E_t[M_j f]} f(x)dxdt = p\int_R\int_0^\infty \xi_{E_t[M_j f]}(x)f(x)t^{p-2}dtdx \\ &= p\int_R f(x)\frac{(M_j f(x))^{p-1}}{p-1}dx \\ &\leqq \frac{p}{p-1}\left[\int_R f^p d\lambda\right]^{1/p}\left[\int_R (M_j f)^{p'(p-1)}d\lambda\right]^{1/p'}.\end{aligned}$$

Since $p'(p-1) = p$ and $1 - 1/p' = 1/p$, the inequality (i) follows. The use of Fubini's theorem is justified because the set $\{(x, t): M_j f(x) > t\}$ is product measurable.

To prove (ii), let $A = \{x: M_l f(x) \geqq M_r f(x)\}$. Then we have, by (1.2),

$$\int_R (Mf)^p d\lambda = \int_A (M_l f)^p d\lambda + \int_{A'} (M_r f)^p d\lambda \leqq 2\left(\frac{p}{p-1}\right)^p \int_R f^p d\lambda;$$

the inequality (ii) follows. ∎

(3.3) REMARKS. (a) The calculation giving (3.2.i) in the above proof is a modification of one given by Flett [4].

(b) The inequalities of Theorem (3.2) are false if $p=1$. In fact, if $f\in\mathfrak{L}_1(R)$ and $0<b<x$, then the inequality $M_l f(x)\geqq x^{-1}\int_0^b f d\lambda$ holds. Thus, except for trivial f's, $M_l f$ is not in $\mathfrak{L}_1(R)$. The fact that we allow arbitrary intervals in our definition of the maximal functions is not, however, the only difficulty in the $\mathfrak{L}_1$ case. If $f(x)=\xi_{[0,1/2]}(x)/[x(\log x)^2]$, then $f\in\mathfrak{L}_1(R)$; but $(M_l f)\xi_{[0,1/2]}\notin\mathfrak{L}_1(R)$. In fact, we have $M_l f(x)\geqq(x|\log x|)^{-1}$ if $x\in]0,\frac{1}{2}[$. (This example appears in [9], p. 33, but with the equality $M_l f(x)=(x|\log x|)^{-1}$. Strict inequality holds, however, for $x\in]1/e, 1/2[$.) In the case $p=1$, there are two replacement results for Theorem (3.2). We state and prove them below.

(3.4) THEOREM. *Let E be a Lebesgue measurable set, and suppose $k\in]0, 1[$. The inequalities*

$$\text{(i)}\qquad \int_E (M_j f)d\lambda \leqq \frac{1}{k}\lambda(E)+\frac{1}{1-k}\int_R f(x)\log^+ f(x)dx \qquad (j=r, l)$$

and

$$\text{(ii)}\qquad \int_E (Mf)d\lambda \leqq \frac{1}{k}\lambda(E)+\frac{2}{1-k}\int_R f(x)\log^+ f(x)dx$$

hold. For $0<p<1$, the inequalities

$$\text{(iii)}\qquad \int_E (M_j f)^p d\lambda \leqq \frac{\lambda(E)^{1-p}}{1-p}\left(\int_R f d\lambda\right)^p \qquad (j=r, l)$$

and

$$\text{(iv)}\qquad \int_E (Mf)^p d\lambda \leqq \frac{2^p\lambda(E)^{1-p}}{1-p}\left(\int_R f d\lambda\right)^p$$

hold.

Our proof of (i) and (ii) (below) is essentially as in [4]. Our proof of (iii) and (iv), based also on (2.2), uses a technique appearing in [3] and [2] (but not in [4]). The definition of $\log^+$ is $\log^+ t=\operatorname{Max}\{\log t, 0\}$. If g is Lebesgue measurable and $\lambda(E)=0$, then $\int_E g d\lambda=0$, even if $\lambda(\{x: g(x)=\pm\infty\})>0$.

Proof. For $j=r, l$, we have

$$\int_E (M_j f)d\lambda = \int_0^\infty \lambda(E_t[M_j f]\cap E)dt = \int_0^{1/k} + \int_{1/k}^\infty$$

$$\leqq \frac{1}{k}\lambda(E)+\frac{1}{1-k}\int_{1/k}^\infty \frac{1}{t}\int_{E_{kt}[f]} f(x)dxdt$$

$$= \frac{\lambda(E)}{k} + \frac{1}{1-k}\int_R f(x)\left\{\int_{1/k}^{\infty} \xi_{E_{kt}[f]}(x)\,\frac{1}{t}\,dt\right\}dx$$

$$= \frac{\lambda(E)}{k} + \frac{1}{1-k}\int_R f(x)\log^+ f(x)\,dx;$$

and so (i) is established. Clearly (ii) can be proved similarly, using (2.2.ii).

To prove (iii), suppose that $\lambda(E)>0$ and $\int_R f d\lambda < \infty$. Let α be any positive real number. We write

$$\int_E (M_j f)^p d\lambda = p\int_0^{\infty} t^{p-1}\lambda(E_t[M_j f]\cap E)\,dt = p\left(\int_0^{\alpha/k} + \int_{\alpha/k}^{\infty}\right)$$

(1)

$$\leqq \frac{\alpha^p}{k^p}\lambda(E) + \frac{p}{1-k}\int_R f(x)\left\{\int_{\alpha/k}^{\infty} t^{p-2}\xi_{E_{kt}[f]}(x)\,dt\right\}dx.$$

The inner integral above is $[f(x)^{p-1}-\alpha^{p-1}]/k^{p-1}(p-1)$ if $f(x)>\alpha$ and is 0 otherwise; it therefore does not exceed $\alpha^{p-1}/k^{p-1}(1-p)$. Thus we get the estimate

$$\int_E (M_j f)^p d\lambda \leqq \frac{\lambda(E)}{k^p}\alpha^p + \frac{p\alpha^{p-1}}{(1-p)k^{p-1}(1-k)}\int_R f d\lambda. \tag{2}$$

Taking $\alpha = (k/(1-k))(\lambda(E))^{-1}\int_R f d\lambda$ (this value minimizes the right side of (2)), we obtain

$$\int_E (M_j f)^p d\lambda \leqq \frac{1}{(1-k)^p}\,\frac{\lambda(E)^{1-p}}{1-p}\left[\int_R f d\lambda\right]^p.$$

Letting $k\to 0$, we obtain (iii). Obvious modifications in the proof yield (iv). ∎

(3.5) REMARK. All of the inequalities in (3.4) are, of course, interesting only if $\lambda(E)<\infty$. Consider the function $\xi=\xi_{[-1,1]}$. We have $M\xi(x)=2/(1+|x|)$ if $|x|\geqq 1$ (see 3.6). Thus ξ and $\xi\log^+\xi$ are in $\mathfrak{L}_1(R)$, but $M\xi$ is not in $\mathfrak{L}_1(R)\cup\mathfrak{L}_p(R)$, $p<1$. This example shows that M does not carry $\mathfrak{L}_1\log^+\mathfrak{L}_1$ into $\mathfrak{L}_1$ or $\mathfrak{L}_1$ into $\mathfrak{L}_p$, $p<1$; and so we cannot expect replacement results for (3.4) when $\lambda(E)=\infty$.

(3.6) BEST CONSTANTS. In various places in the preceding sections, the constants obtained can be shown to be the best possible. First, let $\xi_\delta=\xi_{[-\delta,\delta]}$, $0<\delta<1$. An elementary calculation shows that

$$M\xi_\delta(x) = \begin{cases} 1 & \text{if } |x|\leqq\delta \\ 2\delta/(\delta+|x|) & \text{if } |x|>\delta. \end{cases}$$

We have $\lambda(E_t[M\xi_\delta])=2$ and $t^{-1}\int_{-1}^{1}\xi_\delta d\lambda=\delta+1$, if $t=2\delta(\delta+1)^{-1}$; therefore, 2 in (2.1.ii) is best possible.

Let $p>1$ and $0<\alpha<1$, and put $f_\alpha(x)=x^{-\alpha/p}\xi_{[0,1]}(x)$. The equality $\lim_{\alpha\to 1}\|M_j f_\alpha\|_p\|f_\alpha\|_p^{-1}=p/(p-1)$ shows that the constant in (3.2.i) is the best possible. The example is due to Flett, [4]. Let $0<p<1$, $0<\alpha<1$, and $f_\alpha(x)=x^{-\alpha}\xi_{[0,1]}(x)$. The inequality

$$\left[\int_0^1 (M_1 f_\alpha)^p d\lambda\right]\left[\int_R f_\alpha d\lambda\right]^{-p} \geqq (1-\alpha p)^{-1}$$

shows that the constant in (3.4.iii) is the best possible.

Finally, the constant $(1-k)^{-1}$ in (3.4.i) is the best possible in the following sense. If B_1 and B_2 are constants independent of f and E such that

$$\int_E (M_1 f)\, d\lambda \leqq B_2 \lambda(E) + B_1 \int_R f(x) \log^+ f(x)\, dx,$$

then we have $B_1 \geqq 1$. The following example is due to Flett [4]. Let $E=[0, b]$ and let $f(x)=x^{-1}[\log 1/x]^{-(2+\epsilon)}\xi_E(x)$. Suppose that b is small enough so that f is decreasing on $]0, b]$ and so that $0<x\leqq b$ implies that $\log(\log 1/x)\geqq 0$. An elementary calculation shows that

$$M_1 f(x) = \frac{1}{1+\epsilon}\,\frac{1}{x}\left[\log\frac{1}{x}\right]^{-(1+\epsilon)}, \qquad 0 < x \leqq b.$$

Hence for any constant B_2 we have

$$\left[\int_E M_1 f\, d\lambda - B_2\lambda(E)\right]\left[\int_R f\log^+ f\right]^{-1} \geqq (1+\epsilon)^{-1}\left[\int_0^b \left(\frac{1}{x}\log\frac{1}{x}\right)^{-(1+\epsilon)} dx - B_2 b\right] \times\left[\int_0^b \frac{1}{x}\left(\log\frac{1}{x}\right)^{-(1+\epsilon)} dx\right]^{-1}.$$

Letting $b\to 0$, we obtain $(1+\epsilon)^{-1}$ on the right.

4. The Hardy-Littlewood maximal theorem. Versions of the inequalities (3.2.i), (3.2.ii), and (3.4.i) appear in Hardy and Littlewood's original paper [5]. Sections 2 and 3 combine some of the refinements made in subsequent years, and some related results. As is apparent from the previous references, important contributions have been made by several authors: F. Riesz, Wiener, Flett, and Edwards and Hewitt, to mention those who bear the most influence on our treatment. Hardy and Littlewood based their proofs on a more general maximal theorem. This theorem, which we now prove by the methods of Section 3, is usually called the Hardy-Littlewood maximal theorem.

Notation is as in Sections 1 and 2. We also let f^* denote a decreasing function on $]0, \infty[$ that is equimeasurable with f; that is, $\lambda(E_t[f^*])=\lambda(E_t[f])$ for all $t>0$. (Such functions exist; e.g., f^* can be taken as the inverse of the decreasing function $y\to\lambda(E_y[f])$, with suitable modifications when this function is not strictly decreasing.) The equality

$$\int_R f d\lambda = \int_0^\infty f^* d\lambda = \int_0^\infty \lambda(E_t[f])\, dt \tag{4.1}$$

is a result of (3.1).

(4.2) LEMMA. *The inequality*

$$\int_B f d\lambda \leqq \int_0^{\lambda(B)} f^* d\lambda$$

holds for every Lebesgue measurable set B.

Proof. Clearly we have $\lambda(E_0[f\xi_B]) \leqq \lambda(B)$. Thus $(f\xi_B)^* = 0$ on $]\lambda(B), \infty[$, and we have

$$\int_B f d\lambda = \int_0^{\lambda(B)} (f\xi_B)^* d\lambda \leqq \int_0^{\lambda(B)} f^* d\lambda.$$

We will prove the inequality $(f\xi_B)^* \leqq f^*$(a.e.) used here. In fact, if $g \leqq f$ and $g^*(t_0) > f^*(t_0)$ for some point t_0 of continuity of g^*, then $g^* > f^*$ on some interval $[t_0, t_1]$. Thus we have

$$\lambda(E_{f^*(t_0)}[f^*]) \leqq t_0 < t_1 \leqq \lambda(E_{f^*(t_0)}[g^*]),$$

a contradiction since the extremes are equal to $\lambda(E_{f^*(t_0)}[f])$ and $\lambda(E_{f^*(t_0)}[g])$. Since g^* is continuous a.e., we have $g^* \leqq f^*$ a.e. ∎

The above lemma is well known; it appears, e.g., in [9], p. 31.

We extend f^* by letting $f^*(t) = 0$ if $t \leqq 0$.

(4.3) HARDY-LITTLEWOOD MAXIMAL THEOREM. *Let χ be an increasing non-negative function on $[0, \infty[$, and suppose $f \in \mathfrak{L}_1(R)$. The following inequalities hold:*

(i) $$\int_R \chi \circ (M_j f) d\lambda \leqq \int_R \chi \circ (M_1 f^*) d\lambda \qquad (j = r, l);$$

(ii) $$\int_R \chi \circ (Mf) d\lambda \leqq 2 \int_R \chi \circ (M_1 f^*) d\lambda.$$

Proof. It is easy to see that $M_1 f^*(x) = (1/x)\int_0^x f^* d\lambda$, since f^* is decreasing. It follows from this equality that $M_1 f^*$ is decreasing. By (2.1.i) and (4.2), we have

(1) $$\lambda(E_t[M_j f]) \leqq \frac{1}{t} \int_0^{\lambda(E_t[M_j f])} f^* d\lambda \qquad (t > 0);$$

and this inequality implies that $M_1 f^*(\lambda(E_t[M_j f])) \geqq t$, if $0 < \lambda(E_t[M_j f]) < \infty$. Since $M_1 f^*$ is decreasing, we infer that

(2) $$\lambda(E_t[M_j f]) \leqq \lambda(E_t[M_1 f^*]),$$

if $\lambda(E_t[M_j f]) < \infty$. The equality $\lambda(E_t[M_j f]) = \infty$ would imply, by (1), that $f^*, f \notin \mathfrak{L}_1(R)$; hence, (2) holds for all $t > 0$. Let $F_t[g] = \{x : g(x) \geqq t\}$ $(t > 0,\ g \geqq 0)$. An application of Fatou's lemma, using (2), shows that

(3) $$\lambda(F_t[M_j f]) \leqq \lambda(F_t[M_1 f^*]).$$

Next, let $S=\{x: 0\leqq x_1<x<x_2\Rightarrow\chi(x_1)<\chi(x)<\chi(x_2)\}$. Then χ is strictly increasing on S. On S, we define α as the inverse of $\chi:\chi(\alpha(t))=t$ if $t\in\chi(S)$. If $t\in\chi([0, \infty[)'$, let $\beta=\sup[\{x: \chi(x)<t\}\cup\{0\}]$ and $\gamma=\inf[\{x: \chi(x)>t\}\cup\{\infty\}]$. Then we have $]\beta, \gamma[\subset\chi([0, \infty[)'$, $t\in[\beta, \gamma]$, and β or $\gamma\in\chi([0, \infty[)$. If $\gamma\in\chi([0, \infty[)$, let $\alpha(t)=\inf\{x: \chi(x)=\gamma\}$; if $\beta\in\chi([0, \infty[)$ and $\gamma\notin\chi([0, \infty[)$, let $\alpha(t)=\sup\{x: \chi(x)=\beta\}$. Then $\chi(\alpha(t))$ is either β or γ, and is unequal to t. The function α is thus defined a.e. on $[0, \infty[$ (it is not defined on $\chi(S')$). Let $A=\{t: \chi(\alpha(t))\leqq t\}$ and $B=\{t: \chi(\alpha(t))>t\}$. Then the equalities

$$(4)\qquad \begin{aligned} E_t[\chi\circ g] &= E_{\alpha(t)}[g], \qquad t\in A \\ E_t[\chi\circ g] &= F_{\alpha(t)}[g], \qquad t\in B \end{aligned}$$

hold for any nonnegative function g. Using (2), (3), (4), and our previous results, we calculate as follows:

$$\begin{aligned} \int_R \chi\circ(Mf)d\lambda &= \int_0^\infty \lambda(E_t[\chi\circ Mf])dt \\ &= \int_A \lambda(E_{\alpha(t)}[Mf])dt + \int_B \lambda(F_{\alpha(t)}[Mf])dt \\ &\leqq \int_0^\infty \lambda(E_t[\chi\circ M_1 f^*])dt = \int_R \chi\circ(M_1 f^*)d\lambda. \end{aligned}$$

To prove (ii), we write

$$\begin{aligned} \int_R \chi\circ(Mf)d\lambda &= \int_R \operatorname{Max}\{\chi\circ(M_r f), \chi\circ(M_1 f)\}d\lambda \\ &\leqq \int_R \{\chi\circ(M_r f)+\chi\circ(M_1 f)\}d\lambda \leqq 2\int_R \chi\circ(M_1 f^*)d\lambda. \quad \blacksquare \end{aligned}$$

The constant 2 in (4.3.ii) is the best possible; for, an equimeasurable function for ξ_1 (see Section 3.6) is $\xi_1^*=\xi_{[0,2]}$, and we have

$$\lim_{\substack{p\to 1\\ p>1}}\left[\int_R (M\xi_1)^p d\lambda\right]\left[\int_R (M_1\xi_1^*)^p d\lambda\right]^{-1} = 2.$$

5. Generalizations for R^m. The maximal function Mf defined in Section 1 can be written as

$$Mf(x) = \sup\left\{\lambda(I)^{-1}\int_{x+I} f d\lambda : I \text{ is a finite interval containing } 0\right\}.$$

We see that the mapping M depends on the measure λ and the collection of finite intervals containing 0; averages are taken over intervals containing x. Given a measure space $(X, \mathfrak{A}, \mu)$, what is needed to define formally an operator

M on the positive measurable functions is a family $\mathfrak{B}$ of subsets of X over which to take averages. Maximal functions have been successfully defined and heavily used by several mathematicians by obtaining suitable families $\mathfrak{B}$ on certain measure spaces. Examples are: Calderon [1], to ergodic theorems on locally compact groups; Calderon and Zygmund [2], to singular integrals in R^m; Edwards and Hewitt [3], to pointwise convergence of convolutions on locally compact groups; Smith [7], to harmonic functions in R^m. For the presentation of the maximal theorems in sections 2, 3, and 4, the crucial result is really Lemma (2.1). The other results are obtained from it with no significant use of specific properties of the underlying space R. In this section we prove an analogue of (2.1) for Euclidean m-space R^m, using open spheres in place of intervals. The precise arguments of the proof of (2.1) are not possible if $m \geqq 2$, for the open sets in R^m are not unique disjoint countable unions of spheres. Instead, we need the following covering theorem. All writers dealing with generalized maximal theorems use covering arguments of roughly the same type. The one given below is patterned after Theorem (2.2) of [3]. For $r > 0$, let $S_r = \{x \in R^m : \|x\| < r\}$; and for $n \in Z$ (the integers), let $B_n = S_{2^{-n}}$. Notice that $B_n + B_n = B_{n-1}$. Let $\mathfrak{B} = \{x + B_n : x \in R^m, n \in Z\}$.

(5.1) A COVERING THEOREM. *Let $\mathfrak{B}^\dagger \subset \mathfrak{B}$ and suppose $E \subset R^m$ satisfies*

(i) $\lambda(E + B_n) < \infty$ *for all* $n \in Z$;

(ii) *for each* $x \in E$, *there is some* n *such that* $x + B_n \in \mathfrak{B}^\dagger$;

(iii) $\{n : x + B_n \in \mathfrak{B}^\dagger$ *for some* $x \in E\}$ *is bounded below. Then there are (possibly finite) sequences* $(x_k)_{k=1}^{\infty}$ *and* $(n_k)_{k=1}^{\infty}$ *such that* $x_k \in E$, $(x_k + B_{n_k})_{k=1}^{\infty}$ *is a pairwise disjoint sequence in* $B^\dagger$, *and* $\lambda(E) \leqq 2 \sum_{k=1}^{\infty} \lambda(B_{n_k})$.

Proof. Let $n_1 = \operatorname{Min}\{n : x + B_n \in \mathfrak{B}^\dagger$ for some $x \in E\}$, and choose $x_1 \in E$ such that $x_1 + B_{n_1} \in \mathfrak{B}^\dagger$. Sequences (x_k) and (n_k) satisfying

(1) $\{x_k + B_{n_k}\}_{k=1}^{p}$ is a pairwise disjoint sequence in $\mathfrak{B}^\dagger$ for all p;

(2) $n_k = \operatorname{Min}\{n : x + B_n \in \mathfrak{B}^\dagger$ and $(x + B_n) \subset [\bigcup_{i=1}^{k-1}(x_i + B_{n_i})]'$, some $x \in E\}$;

(3) $x_{p+1} \in [\bigcup_{i=1}^{p}(x_k + B_{n_{k-1}})]'$ for all p

will be defined by induction. Thus suppose that $(x_k)_{k=1}^{p}$ and $(n_k)_{k=1}^{p}$ satisfy (1), (2), (3). If $E \subset \bigcup_{k=1}^{p}[x_k + B_{n_{k-1}}]$, we obtain a finite sequence satisfying (1) and (2) and $E \subset \bigcup_{k=1}^{p}(x_k + B_{n_{k-1}})$. Otherwise, let $x \in E \cap [\bigcup_{k=1}^{p}(x_k + B_{n_{k-1}})]'$ and let j be the smallest integer such that $x + B_j \in \mathfrak{B}^\dagger$. We will show that $x + B_j \subset [\bigcup_{k=1}^{p}(x_k + B_{n_k})]'$. If $(x + B_j) \cap (x_1 + B_{n_1}) \neq \varnothing$, we have $x \in x_1 + (B_{n_1} + B_j) \subset x_1 + B_{n_1 - 1}$; a contradiction. If there are k's such that $(x + B_j) \cap (x_k + B_{n_k}) \neq \varnothing$, let q be the least among them $(1 < q \leqq p)$. Then the inclusion $x + B_j \subset [\bigcup_{i=1}^{q-1}(x_i + B_{n_i})]'$ holds. Therefore, the inequality $j \geqq q$ holds, and $x \in x_q + B_{n_q - 1}$; a contradiction. We can thus define $n_{p+1} = \operatorname{Min}\{j : x + B_j \in \mathfrak{B}^\dagger$ and $(x + B_j) \subset [\bigcup_{i=1}^{p}(x_i + B_{n_i})]'$, some $x \in E\}$, and select x_{p+1} such that $x_{p+1} + B_{n_{p+1}} \in \mathfrak{B}^\dagger$.

We claim that $E \subset \bigcup_{k=1}^{\infty}(x_k + B_{n_k - 1})$ (this is already established if the sequences are finite). We have $\lim_{k \to \infty} n_k = \infty$; proof:

$$\sum_{k=1}^{\infty} \lambda(B_{n_k}) = \sum_{k=1}^{\infty} \lambda(x_k + B_{n_k}) < \lambda(E + B_{n_1}) < \infty.$$

Hence, for given $x \in E$ and $p \in Z$, we must have $(x+B_p) \cap (x+B_{n_k}) \neq \varnothing$ for some k; if not, x and p would have been selected for x_j and n_j as soon as n_j exceeded p. If q is the least integer such that $(x+B_p) \cap (x_q+B_{n_q}) \neq \varnothing$, then we argue as before to obtain $x \in x_q + B_{n_q-1}$.

Finally, we have

$$\lambda(E) \leqq \sum_{k=1}^{\infty} \lambda(B_{n_k-1}) \leqq 2 \sum_{k=1}^{\infty} \lambda(B_{n_k}). \quad \blacksquare$$

Let λ denote m-dimensional Lebesgue measure.

(5.2) THEOREM. *Let $p \geqq 1$, and suppose $f \in \mathfrak{L}_p(R^m)$. Define*

$$Mf(x) = \sup_{r>0} \lambda(S_r)^{-1} \int_{x+S_r} f d\lambda.$$

There is a constant α such that $\lambda(E_t[Mf]) \leqq (2/t) \int_{E_{\alpha t}[Mf]} f d\lambda$ for all $t > 0$.

Proof. With notation as above, let

$$M'f(x) = \sup_{n \in Z} \lambda(B_n)^{-1} \int_{x+B_n} f d\lambda.$$

Small changes in x yield small changes in $\int_{x+S_r} f d\lambda$ for fixed r; it follows easily from this fact that Mf and $M'f$ are Borel measurable, in fact lower semi-continuous. Define $\mathfrak{B}^\dagger = \{x+B_n : \lambda(B_n)^{-1} \int_{x+B_n} f d\lambda > t\}$. Then $E_t[M'f]$ satisfies (5.1.ii) for this $\mathfrak{B}^\dagger$. Condition (5.1.iii) is also satisfied, for there cannot be sequences $(x_i)_{i=1}^{\infty}$ and $(n_i)_{i=1}^{\infty}$ such that $\lim_{i \to \infty} n_i = -\infty$ and $\int_{x+B_{n_i}} f > t\lambda(B_{n_i})$. This last assertion is obvious if $p = 1$ and is an easy application of Hölder's inequality if $p > 1$. Condition (5.1.i) is satisfied for each set $E_j = B_j \cap E_t[M'f]$, $j \in Z$; and clearly (ii) and (iii) are also satisfied for the E_j's. For fixed j, then, let $(x_k+B_{n_k})_{k=1}^{\infty}$ be the sequence guaranteed by (5.1). The inequality

$$\lambda(E_j) \leqq 2t^{-1} \int_U f d\lambda \left(U = \bigcup_{k=1}^{\infty} (x_k + B_{n_k}) \right)$$

thus holds. If $x \in U$ and $x \in x_k + B_{n_k}$, then we have

$$\lambda(B_{n_k-1})^{-1} \int_{x+Bn_k-1} f d\lambda = 2^{-m} \lambda(B_{n_k})^{-1} \int_{x+B_{nk-1}} f d\lambda > 2^{-m} t;$$

therefore, $U \subset E_{2^{-m}t}[M'f]$. We conclude, letting $j \to -\infty$, that

$$\lambda(E_t[M'f] \leqq \frac{2}{t} \int_{E_{\beta t}[M'f]} f d\lambda \quad (\beta = 2^{-m}).$$

For a given $r>0$, let n be the unique integer such that $B_n \subseteq S_r \subset B_{n-1}$. Then $\lambda(S_r)^{-1}\int_{x+S_r} f d\lambda \leqq 2^m \lambda(B_{n-1})^{-1}\int_{x+B_{n-1}} f d\lambda$ for any $x \in R^m$. Hence we have $Mf \leqq 2^m M'f$ and $E_t[Mf] \subset E_{t2^{-m}}[M'f]$. The inequality

$$\lambda(E_t[Mf]) \leqq \frac{2}{t}\int_{E_{\alpha t}[Mf]} f d\lambda, \quad \alpha = 2^{-2m}$$

follows. ∎

The proofs of the R^m analogues of (2.2), (3.2), (3.4), and (4.3) are almost identical to those given in Sections 2, 3, 4 for $m=1$; (5.2) is used in place of (2.1). Of course, the constants change. Lemmas (3.1) and (4.1) offer no difficulty in R^m.

The family $\{x+S_r: x \in R^m, r>0\}$ over which the averages are taken in (5.2) can be replaced by other families. For example, m-dimensional cubes symmetric about the origin would do. In fact, m-dimensional rectangles symmetric about O and satisfying the condition that the ratio of the maximal side length to the minimal side length does not exceed a fixed constant could replace the S_r's. Sufficient conditions (on the sets over which averages are taken) to yield maximal theorems are given in each of [2], [3], and [7].

Hardy and Littlewood devoted the main part of their proofs to the discrete analogues of the theorems in Sections 3 and 4. It is instructive to formulate these analogues (for Z, e.g.). The facts in these cases are corollaries of the results in Sections 2, 3, and 4. Similarly, there are results for sums of multiple sequences (maximal functions for Z^m). These follow from the R^m theorems.

The author would like to thank Professor Edwin Hewitt for the original suggestion that a paper of this type be written, and for helpful suggestions during its preparation.

ON QUALITATIVE PROBABILITY

C. VILLEGAS, Instituto de Matemática y Estadística, Montevideo

1. Introduction. The rapid development of mathematical probability over the past thirty years was based on the firm axiomatic foundation laid out by Kolmogorov in 1933 [6]. Following Kolmogorov, almost all mathematical papers on probability which have been published since then, have considered probability as a (countably additive) measure P defined on a σ-algebra of sets of a space Ω, satisfying $P(\Omega)=1$. Although this formulation is entirely satisfactory from a mathematical point of view, problems still remained in the applications in several fields, suggesting the desirability of some changes in the general axiomatic theory. Thus, Glivenko [4], Koopman [7] and Halmos [5] considered the events as undefined terms, subject to the usual operations of union, intersection and complementation, satisfying the axioms of a Boolean algebra [11]. It has been pointed out also that a probability measure satisfying $P(\Omega)=1$ cannot be applied to some problems in which unbounded measures naturally occur. We cannot speak for instance of a probability distribution which is uniform on the whole real axis, or on the whole plane, or on all integers. One objection that usually arises when unbounded measures are proposed is that probability is used to build models in which it plays the role of an idealized frequency, and therefore its value can never exceed one. Trying to solve this difficulty without altering the frequency interpretation of probability, Rényi [9] presented a modified axiomatic theory, in which conditional probability, instead of absolute probability, is the fundamental concept. He shows then that under general conditions a (possibly unbounded) measure can be defined, in terms of which the conditional probability is given by $P(A\,|B)=\mu(A\cap B)/\mu(B)$.

There is however an increasing number of statisticians who believe that, by adhering exclusively to an objective interpretation of probability, the field of application of probability theory has been unnecessarily narrowed. They argue that there is a need for using also personal or subjective probabilities, and that such probabilities have an important role to play in various fields of application, notably in statistical inference and decision theory. Motivated in part by this subjective interpretation of probability there have been various attempts to build an axiomatic theory in which qualitative probability is the fundamental concept, and the numerical probabilities are derived from it as the only compatible probability measure. Clearly, qualitative statements such as "the event A is less probable than B" are closer to our intuitive representation of the situation considered than similar statements concerning numerical probabilities, like "the probability of A is equal to P," even when a frequency interpretation is possible.

An axiomatic theory based on qualitative probability was given by Bernstein in 1917 [1]. Slightly improved axioms were proposed later by de Finetti ([2], Sec. 13; [3]). Bernstein, de Finetti and Koopman derived an additive probability measure from a qualitative probability under the simplifying assumption

that, for any integer n, there are n mutually exclusive, equally probable events. L. J. Savage [10] has shown that this strong assumption may be relaxed, thereby gaining in generality at the expense of a corresponding loss in simplicity. Kraft, Pratt and Seidenberg [8] considered the case of finite Boolean algebras, showing, for example, that there are qualitative probabilities on finite Boolean algebras without any compatible measure. Villegas [13] proved that, if an atomless and monotonely continuous qualitative probability is defined in a Boolean σ-algebra of sets, then there is one and only one compatible additive probability measure, and it is countably additive.

Although the present writer subscribes to the opinion that the interpretation given to the word probability may be different in different contexts, and even in different parts of the same problem, in this paper we shall not enter into the controversy over the objective vs. subjective interpretation of probability. We simply remark that a qualitative probability, as a numerical one, may be interpreted in either way, and therefore the following axiomatic theory is compatible with both interpretations of probability.

2. Events. We shall consider the *events* as undefined elements of a *Boolean ring* $\mathfrak{R}$. The two ring operations, addition and multiplication, are also called *symmetric difference* $+$ and *intersection* $\cap$. As is well known, the *union* $\cup$ of two events and the Boolean *inclusion* $\subset$ may be defined in terms of the ring operations. The Boolean inclusion is a partial order with a first element, O, which is the zero of the ring, and is called the *impossible event.* Two events, A, B are *incompatible* or *mutually exclusive* if $A \cap B \equiv O$ (in this paper the identity of events will be denoted by the sign $\equiv$, leaving the sign $=$ for the relation "equally probable" to be introduced later). A *Boolean algebra* $\mathfrak{A}$ of events is a Boolean ring with a unit element, which is called the *sure event*, and is usually denoted by Ω. Unless the contrary is specified, we shall not assume the existence of a sure event.

A fundamental result in the theory of Boolean rings is that every Boolean ring is isomorphic to a ring of sets of a space. This result is due to Stone [12] and his construction has the following simple interpretation. A *possible realization* of the ring of events $\mathfrak{R}$ is a classification of the elements of $\mathfrak{R}$ into two classes: the events which *occur* and the events which *do not occur*. This classification is such that:

(i) the class of the events which occur is non-empty;

(ii) $A+B$ occurs if and only if only one of the events A, B occurs;

(iii) $A \cap B$ occurs if and only if both events A, B occur.

It can be easily shown that the impossible event O never occurs. If A is an event different from O, then it can be proved (using Zorn's lemma or an equivalent) that there is one realization in which A occurs (theorem of existence of realizations). The set Ω of all possible realizations is the *possibility space* of the ring $\mathfrak{R}$. Given an event A, let $\overline{A}$ be the set of all realizations of $\mathfrak{R}$ in which A does occur. Using the theorem of existence of realizations it can be proved easily that the natural correspondence $A \to \overline{A}$ is a Boolean isomorphism between $\mathfrak{R}$ and the

Boolean ring of sets $\overline{\mathfrak{R}} = \{\overline{A}: A \in \mathfrak{R}\}$. We may identify, therefore, the events with the sets of $\overline{\mathfrak{R}}$, that is, we can think of the events as sets of realizations.

We shall say that an event A is the *intersection* $\cap_{i=1}^{\infty} A_i$ *of a denumerable family of events* $\{A_i: i=1, 2, \cdots\}$ if from $B \subset A_i$, $i=1, 2, \cdots$ it follows that $B \subset A$ (the words set, family and collection will be used as synonyms in this paper). The *union of a denumerable family of events* is defined in a similar way. A *Boolean σ-ring* is a Boolean ring in which every denumerable collection of elements has a union and an intersection. We shall say that a Boolean ring is a *Boolean δ-ring* if every denumerable collection of events has an intersection. In general, Boolean δ-rings (or σ-rings) are not isomorphic to Boolean δ-rings (or σ-rings) of sets of a space Ω.

3. Qualitative probability. A *total pre-order* in the Boolean ring of events $\mathfrak{R}$ is a relation $\leqq$ such that the following conditions obtain:

Comparability (TPO_1): If A and B are events, then either $A \leqq B$ or $B \leqq A$;

Transitivity (TPO_2): If $A \leqq B$ and $B \leqq C$, then $A \leqq C$.

Obviously, from (TPO_1) it follows immediately that for any event A, we have $A \leqq A$. If $A \leqq B$ holds but $B \leqq A$ does not, then we shall write, as usual, $A < B$. A *qualitative probability* in the Boolean ring of events $\mathfrak{R}$ is a total pre-order satisfying the following conditions:

Monotony (QP_1): If $B_1 \cap B_2 \equiv O$, then from $A_1 \leqq B_1$ and $A_2 \leqq B_2$ it follows that

$$A_1 \cup A_2 \leqq B_1 \cup B_2,$$

and if, in one of the first two inequalities, the sign $\leqq$ is replaced by $<$, then the last one holds with the sign $\leqq$ replaced by $<$.

(QP_2): For any event A, $O \leqq A$.

The above set of axioms is not independent. In fact, as was pointed out to the author by J. J. Schäffer, it can be shown that (TPO_2) is a consequence of (TPO_1) and (QP_1). If $\leqq$ is a qualitative probability and $A \leqq B$, then we shall say that A is less probable than B. As usual, instead of $A \leqq B$ we shall write also $B \geqq A$ and we shall say that B is more probable than A. If $A < B$ (or equivalently $B > A$), then we shall say that A is strictly less probable than B (or that B is strictly more probable than A). If $A \leqq B$ and $B \leqq A$, then we shall write $A = B$ and we shall say that A and B are equally probable events. The pair $(\mathfrak{R}, \leqq)$ in which $\mathfrak{R}$ is a Boolean ring and $\leqq$ is a qualitative probability defined in $\mathfrak{R}$ will be called a *qualitative probability ring*. A *qualitative probability algebra* is a pair $(\mathfrak{A}, \leqq)$ in which $\mathfrak{A}$ is a Boolean algebra, and $\leqq$ is a qualitative probability defined on $\mathfrak{A}$ and satisfying

(QPA): $O < \Omega$.

If $A = O$, we shall say that A is a *null* or an *almost impossible event*. In a qualitative probability algebra, we shall say that an event A is an *almost sure event* if $A = \Omega$. Two events A, B will be called *almost incompatible* if $A \cap B = O$. The following propositions are left as exercises for the reader.

(1) *Sharpened transitivity.* If $A \leqq B$ and $B < C$, then $A < C$.

(2) *Compatibility with the inclusion.* If $A \subset B$, then $A \leqq B$.

(3) If $A_2 \subset A_1$ and $B_2 \subset B_1$, then from $A_1 \leqq B_1$ and $A_2 \geqq B_2$ it follows that

$$A_1 - A_2 \leqq B_1 - B_2.$$

(4) *Duality.* In a qualitative probability algebra, if $A \leqq B$, then $B^c \geqq A^c$, where the superscript c denotes complementation.

A uniform partition of order n of an event $A > O$ is a collection of n equally probable, almost incompatible nonnull events, the union of which is A.

LEMMA. *If $\{A_i: i=1, \cdots, m\}$ is a uniform partition of order m of an event $E > O$, and $\{B_j: j=1, \cdots, n\}$ is a uniform partition of order $n \leqq m$ of the same event E, then $A_i \leqq B_j$ for every i, j.*

Proof. Assume, on the contrary, that $B_j < A_i$ for some i, j. Then the same relationship must hold for all i, j because the partitions are uniform. Hence, by monotony we have

$$\bigcup_{j=1}^{n} B_j < \bigcup_{i=1}^{n} A_i,$$

and therefore

$$E < \bigcup_{i=1}^{n} A_i,$$

contrary to the assumption that the A_i's constitute a uniform partition of E.

COROLLARY 1. *If $\{A_i\}$, $\{B_j\}$ are two uniform partitions of the same order, of an event $E > O$, then $A_i = B_j$ for all i, j.*

COROLLARY 2. *If $\{A_i\}$ is a uniform partition of order m of an event $E > O$, and $\{B_j\}$ is a uniform partition of order $n = m\,k$ of the same event, then, for any i, A_i and the union of k events B_j are equally probable events.*

4. Compatible additive measures. Let $\mathfrak{R}$ be a Boolean ring, and let $\mathfrak{F}$ be a subset of $\mathfrak{R}$, which contains the impossible event O. An *additive functional* on $\mathfrak{F}$ is a real valued function ϕ defined on $\mathfrak{F}$ such that

$$\phi(A \cup B) = \phi(A) + \phi(B) \tag{4.1}$$

whenever A, B, $A \cup B$ belong to $\mathfrak{F}$ and $A \cap B \equiv O$. It follows immediately that $\phi(O) = 0$. An additive functional on $\mathfrak{F}$ is *compatible* with a qualitative probability $\leqq$ defined on $\mathfrak{R}$, if $A \leqq B$ is equivalent to $\phi(A) \leqq \phi(B)$ for all pairs of events A, B belonging to $\mathfrak{F}$. Thus, if an additive functional ϕ defined on $\mathfrak{F}$ is compatible with a qualitative probability $\leqq$, the knowledge of ϕ implies the knowledge of the qualitative probability within $\mathfrak{F}$. An *additive measure* on $\mathfrak{F}$ is a nonnegative additive functional on $\mathfrak{F}$, i.e., is an additive functional μ defined on $\mathfrak{F}$ such that $\mu(A) \geqq 0$ for all $A \in \mathfrak{F}$. Since $A \geqq O$ for all events A, it follows that, if an additive functional is compatible with a qualitative probability, then it is an additive

measure. An *additive probability measure* P is an additive measure defined in a Boolean algebra such that $P(\Omega)=1$. We shall say that a qualitative probability ring is *fissionable* if every event can be partitioned in two equally probable events, and that it is reducible if it is fissionable and for every pair of events A, B such that $O<A<B$, there is a uniform partition $\mathcal{E}$ of B such that $E<A \leqq B-E$ for every $E\in\mathcal{E}$. Clearly, if $(\mathfrak{R}, \leqq)$ is fissionable, then every nonnull event has uniform partitions of order $n=2^p$ for any positive integer p. Given an event $E\in\mathfrak{R}$, the *section of* $\mathfrak{R}$ *determined by* E is the collection of all events $A\in\mathfrak{R}$ such that $A\leqq E$.

THEOREM 4.1. *If* $(\mathfrak{R}, \leqq)$ *is a reducible qualitative probability ring, then there is one and only one (up to an arbitrary scale factor) compatible additive measure on any section of* $\mathfrak{R}$.

Proof. We assume that there are nonnull events, since otherwise the theorem is trivial. The proof will be divided into several steps.

(a) *Uniqueness.* Let μ be a compatible additive measure defined on the section of $\mathfrak{R}$ determined by the event $E>O$. Let $\{E_i: i=1, \cdots, n\}$ be a uniform partition of E of order $n=2^p$. Then we have

$$\mu(E) = \sum_{i=1}^{n} \mu(E_i).$$

But, since the events E_i are equally probable, we have $\mu(E_1)= \cdots =\mu(E_n)$ and therefore, for $m\leqq n$, $\mu(E_1\cup \cdots \cup E_m)=\mu(E)m/n$. By compatibility $\mu(E)>0$, and consequently

$$\frac{\mu(E_1 \cup \cdots \cup E_m)}{\mu(E)} = \frac{m}{n}.$$

Consider now an arbitrary event $A\leqq E$. Let

$$(4.2) \qquad \begin{aligned} r &= \max\left\{m: \bigcup_{i=1}^{m} E_i \leqq A, m = 0, \cdots, n\right\} \\ s &= \min\left\{m: A \leqq \bigcup_{i=1}^{m} E_i, m = 0, \cdots, n\right\}. \end{aligned}$$

Note that, by convention, $\bigcup_{i=1}^{0} E_i \equiv O$. By compatibility we have then

$$\frac{r}{n} \leqq \frac{\mu(A)}{\mu(E)} \leqq \frac{s}{n}.$$

The uniqueness of $\mu(A)/\mu(E)$ follows immediately from the fact that n may be made arbitrarily large and $s-r\leqq 1$.

(b) *Definition of* μ. In order to prove that the above procedure gives a consistent definition for $\mu(A)/\mu(E)$, it is sufficient to show that, if $\mathcal{E}'=\{E_i': i=1, \cdots, n'\}$ and $\mathcal{E}''=\{E_i'': i=1, \cdots, n''\}$ are two uniform partitions of E of

orders $n'=2^{p'}$, $n''=2^{p''}$, and if r', s'; r'', s'' are the corresponding numbers defined as in (4.2) then

$$\frac{r'}{n'} \leqq \frac{s''}{n''}. \tag{4.3}$$

Let $\mathcal{E}=\{E_i: i=1, \cdots, n\}$ be a uniform partition of order $n=n'n''$. Since any element of $\mathcal{E}'$ and the union of n'' elements of $\mathcal{E}$ are equally probable events, from $\bigcup_{i=1}^{r'} E_i' \leqq A$ it follows that $\bigcup_{i=1}^{r'n''} E_i \leqq A$ and therefore $r'n'' \leqq r$, or, equivalently, $r'/n' \leqq r/n$. Similarly, $s/n \leqq s''/n''$, and from the last two inequalities (4.3) follows immediately.

(c) *Additivity.* Let A, B be two disjoint events, and let $C \equiv A \cup B$. We assume that A, B and C belong to the section of $\mathfrak{R}$ determined by E. Let $\{E_i: i=1, \cdots, n\}$ be a uniform partition of E of order $n=2^p$ and let $r(A)$, $s(A)$; $r(B)$, $s(B)$; $r(C)$, $s(C)$ be the corresponding numbers defined as in (4.2). Then we have

$$\bigcup_{i=1}^{r(C)} E_i \leqq C \leqq \bigcup_{i=1}^{s(C)} E_i, \qquad \bigcup_{i=1}^{s(A)} E_i \geqq A \geqq \bigcup_{i=1}^{r(A)} E_i.$$

By subtraction we have

$$\bigcup_{i=s(A)+1}^{r(C)} E_i \leqq B \leqq \bigcup_{i=r(A)+1}^{s(C)} E_i. \tag{4.4}$$

These inequalities are also valid when the unions are empty; i.e., when $r(A)=s(C)$ or when $r(C) \leqq s(A)$, in which case, by convention, the empty unions are equal to the impossible event O. From (4.4) it follows that

$$r(C) - s(A) \leqq r(B) \leqq s(B) \leqq s(C) - r(A).$$

Multiplying by $\mu(E)/n$ and letting $n=2^p \to \infty$, we get

$$\mu(C) - \mu(A) \leqq \mu(B) \leqq \mu(C) - \mu(A).$$

Since the first and last members are equal, (4.1) follows immediately.

(d) *Compatibility.* Assume that $A < B \leqq E$. Since $(\mathfrak{R}, \leqq)$ is reducible there is an event $C \subset B$ such that $A \leqq C < B$. Let $\{E_i: i=1, \cdots n\}$ be a uniform partition of E of order $n=2^p$ such that $E_1 \cup E_2 \leqq B-C$. Let $s(A)$, $r(A)$, $s(B)$, $r(B)$ be defined as in (4.2). Then by the axiom of monotony, from

$$\bigcup_{i=1}^{s(A)-1} E_i \leqq C \quad \text{and} \quad E_{s(A)} \cup E_{s(A)+1} \leqq B - C$$

it follows that

$$\bigcup_{i=1}^{s(A)+1} E_i \leqq B.$$

Hence $s(A)+1 \leqq r(B)$ and therefore $\mu(A) < \mu(B)$. If, on the other hand, $A=B$, then the definition of μ shows that $\mu(A)=\mu(B)$.

THEOREM 4.2 *If* $(\mathfrak{A}, \leqq)$ *is a reducible qualitative probability algebra, then there is one and only one additive probability measure which is compatible with the qualitative probability* $\leqq$.

Proof. This theorem follows immediately from the previous one.

We shall say that a qualitative probability ring $(\mathfrak{R}, \leqq)$ is *σ-bounded* if there is a sequence of events $E_1 \leqq E_2 \leqq \cdots$ such that, if $A \in \mathfrak{R}$, then there is an integer n for which $A \leqq E_n$.

THEOREM 4.3. *If* $(\mathfrak{R}, \leqq)$ *is a reducible and σ-bounded qualitative probability ring, then there is one and only one (up to an arbitrary scale factor) compatible additive measure.*

Proof. Let $O < E_1 \leqq E_2 \leqq \cdots$ be a sequence of events such that $A \leqq E_n$ for any event A and some integer n, depending on A. Let $\mathfrak{F}_n$ be the family of all events which are less probable than E_n. Let μ_n be the additive measure defined on $\mathfrak{F}_n$ which is compatible with $\leqq$ and is such that $\mu_n(E_n) = 1$. Obviously, if $m \leqq n$ we will have $\mu_n(E_m) > 0$. Define $\mu(E_1) > 0$ arbitrarily, and then define $\mu(E_n)$ by

$$\mu_n(E_1) = \frac{\mu(E_1)}{\mu(E_n)} \cdot \tag{4.5}$$

Then for $A \in \mathfrak{F}_n$ define

$$\mu(A) = \mu_n(A)\mu(E_n). \tag{4.6}$$

It is clear that this is a compatible additive measure; however, we must prove that this definition is consistent, or, in other words, we have to prove that, if $A \in \mathfrak{F}_n$, $A \in \mathfrak{F}_m$, then

$$\mu_n(A)\mu(E_n) = \mu_m(A)\mu(E_m). \tag{4.7}$$

Assume that $m < n$. Then for any $A \in \mathfrak{F}_m$,

$$\mu_n(A)/\mu_n(E_m) = \mu_m(A) \tag{4.8}$$

because the left hand member of this equality is a compatible additive measure defined in $\mathfrak{F}_m$ which gives to E_m the value 1. Since $E_1 \in \mathfrak{F}_m$, from (4.8) we have

$$\mu_n(E_1)/\mu_n(E_m) = \mu_m(E_1). \tag{4.9}$$

Then from (4.5) and (4.9) we get

$$\mu_n(E_m)\mu(E_n) = \mu(E_m). \tag{4.10}$$

By multiplying of (4.8) and (4.10), we get equation (4.7) immediately.

5. Monotone continuity. We shall say that a sequence of events $\{A_n : n = 1, 2, \cdots\}$ *converges from above to* A and we shall write $A_n \searrow A$, if it is a monotone decreasing sequence which converges to A, that is, if $A_1 \supset A_2 \supset \cdots$ and $\bigcap_{n=1}^{\infty} A_n \equiv A$. A qualitative probability $\leqq$ defined on a Boolean δ-ring is monotonely continuous if from $A_n \searrow A$ and $A_n \geqq B$ for all n, it follows that $A \geqq B$.

If $\mathfrak{R}$ is a Boolean δ-ring, and $\leqq$ is a monotonely continuous qualitative probability defined on $\mathfrak{R}$, then the pair $(\mathfrak{R}, \leqq)$ will be called a *qualitative probability δ-ring.*

THEOREM 5.1. *Let $\mathfrak{R}$ be a Boolean δ-ring, let $\leqq$ be a qualitative probability defined on $\mathfrak{R}$, and let μ be a compatible additive measure. Then μ is countably additive if and only if $\leqq$ is monotonely continuous.*

Proof. The proof is omitted since it is similar to the corresponding proof for Boolean algebras given in [13].

THEOREM 5.2. *Any atomless qualitative probability δ-ring is reducible.*

Proof. By Theorem 3.4 of [13], the qualitative probability δ-ring is fissionable, and therefore, given two events A, B such that $O<A<B$, there is a sequence of uniform partitions of B, $\mathcal{E}_n = \{E_1^{(n)}, \cdots, E_{2^n}^{(n)}\}$, such that

$$E_m^{(n-1)} \equiv E_{2m-1}^{(n)} \cup E_{2m}^{(n)}.$$

That is, the elements of the partition $\mathcal{E}_n$ are obtained by partitioning each element of $\mathcal{E}_{n-1}$ in two equally probable events. By Lemma 3.2 of [13], the limit of the monotone sequence $\{E_1^{(n)}\}$ is a null event, and therefore there is one n such that $E_1^{(n)}<A$. On the other hand, the sequence $\{C_n\}$ defined by $C_n \equiv B - E_1^{(n)}$ is a monotone increasing sequence which converges to an event which differs from B at most by a null event; therefore there is one n such that $A \leqq C_n < B$.

THEOREM 5.3. *Let $(\mathfrak{R}, \leqq)$ be a σ-bounded, atomless qualitative probability δ-ring. Then there is one and only one (up to an arbitrary scale factor) compatible additive measure, and it is countably additive.*

Proof. This is an immediate consequence of Theorems 5.1, 5.2 and 4.3.

A THEOREM ON REPEATING DECIMALS

W. G. LEAVITT, University of Nebraska

It is well known that a real number is rational if and only if its decimal expansion is a repeating decimal. For example, $2/7 = .285714285714 \cdots$. Many students also know that if n/m is a rational number reduced to lowest terms (that is, n and m relatively prime), then the number of repeated digits (we call this the *length of period*) depends only on m. Thus all fractions with denominator 7 have length of period 6. A sharp-eyed student may also notice that when the period (that is, the repeating digits) for 2/7 is split into its two half-periods 285 and 714, then the sum $285+714=999$ is a string of nines. A little experimentation makes it appear likely that this is always true for a fraction with the denominator 7, as well as for fractions with denominators 11, 13, or 17. A natural conjecture is that all primes with even length of period (note that many primes, such as 3 and 31, have odd length of period) will have a similar property. This conjecture is, in fact, true but it is unfortunately not a criterion for primeness, since many composite numbers (such as 77) also have the property. The relevant theorem appears not to be well known, although it was discovered many years ago. (L. E. Dickson [see 1, p. 163] attributes the result to E. Midy, Nantes, 1836). The proof of the theorem is simple and elegant, and since it also provides a nice example of the usefulness of the concept of the order of an element of a group, it deserves to be better known.

In the following, we will develop from the beginning the theory of repeating decimals. This is to provide the necessary machinery for the proof of Midy's theorem, as well as for completeness.

Write (n, m) for the G.C.D. of n and m. Assuming n/m is a fraction reduced to lowest terms is thus equivalent to supposing $(n, m)=1$. (Note: we are interested only in positive fractions, so we restrict ourselves to $m>1$ and $n>0$.) Without loss of generality, we may also assume $(10, m)=1$, for if m is divisible by 5 or 2 we could multiply numerator and denominator of n/m by the appropriate power of 2 or 5 to obtain $n/m=10^{-h}n'/m'$ (for some integer $h\geqq 1$), where we still have $(n', m')=1$, and m' is not divisible by either 2 or 5. Since dividing by 10^h simply moves the decimal place, it is clear that the repeating digits of n/m are the same as those for n'/m'.

Write $n/m=c+h_1/m$ where $0<h_1<m$ and $c\geqq 0$ is an integer. Since $n=cm+h_1$, it is clear that we still have $(h_1, m)=1$. Also, since c may be any integer, the

repeating digits we are after will be those of h_1/m. Now we are interested only in the digits obtained upon division by m (not in the position of the decimal point). Thus when in the division process we bring down the first zero, we are actually dividing $10h_1$ by m. Let a_1 be the first digit in the quotient ($0 \leqq a_1 \leqq 9$) and let h_2 be the next remainder, then

$$h_2 = 10h_1 - a_1m.$$

Repeating the division process to obtain the next digit a_2 and the next remainder h_3,

$$h_3 = 10h_2 - a_2m.$$

Thus in general for any $t \geqq 2$,

$$h_t = 10h_{t-1} - a_{t-1}m. \tag{1}$$

Substituting for h_{t-1} from the preceding relation of (1) yields

$$h_t = 10^2h_{t-2} - (10a_{t-2} + a_{t-1})m,$$

and in general for any s (where $t > s \geqq 1$),

$$h_t = 10^sh_{t-s} - (10^{s-1}a_{t-s} + 10^{s-2}a_{t-s+1} + \cdots + 10a_{t-2} + a_{t-1})m. \tag{2}$$

Note that since $(m, 10h_1) = 1$ it follows from (1) that m and h_2 have no common factors, so $(m, 10h_2) = 1$. It is thus clear (inductively) that for all the remainders h_i we have $(m, 10h_i) = 1$. But the total number of integers less than m and prime to m is finite. (Remark that this number is the so-called "Euler ϕ-function" $\phi(m)$). Accordingly there must exist integers k and $k+r$ such that $h_k = h_{k+r}$. Then from (2)

$$10^rh_k - h_{k+r} = (10^{r-1}a_k + \cdots)m,$$

so that m divides $(10^r - 1)h_k$. But $(m, h_k) = 1$, and so m divides $10^r - 1$ (write this $m \mid 10^r - 1$). Thus $10^r \equiv 1 \pmod{m}$, and we assume that r is the least such integer. Another way of saying this is: r is the order of 10 in the multiplicative group (modulo m) of all integers $< m$ and relatively prime to m. As we mentioned above, the order of this group is $\phi(m)$, so by the Lagrange theorem, $r \mid \phi(m)$.

Writing, as we have indicated, the decimal expansion of h_1/m as $.a_1a_2 \cdots$, we can prove:

THEOREM 1. *If r is the order of 10 modulo m, then $a_{r+i} = a_i$ for all $i \geqq 1$. Conversely, if there exist positive integers k and u such that $a_{u+i} = a_i$ for all $i \geqq k$, then $r \mid u$.*

Proof. From (2) we have $h_{r+i} \equiv 10^rh_i \pmod{m}$, and since $10^r \equiv 1 \pmod{m}$, it follows that $h_{r+i} \equiv h_i \pmod{m}$. But all remainders $h_i < m$, so this implies $h_{r+i} = h_i$. Then from (1)

$$0 = h_{r+i+1} - h_{i+1} = (a_{r+i} - a_i)m,$$

whence

$$a_{r+i} = a_i. \tag{3}$$

Conversely, suppose $a_{u+i}=a_i$ for all $i \geqq k$. If we take w large enough so that $wr \geqq k$, then this says that $a_{u+wr+i}=a_{wr+i}$ for all $i \geqq 1$, so by (3), $a_{u+i}=a_i$. Now let $d=(u, r)$ and take advantage of the fact that there exist integers s and t such that $su+tr=d$. We know that either s or t must be positive, so suppose $s>0$ (same proof if $t>0$). Then $a_{su+i}=a_i$ and by using (3), $a_{su+tr+i}=a_i$. Thus $a_{d+i}=a_i$. Once again, using (1), it is clear that

$$10(h_{d+i} - h_i) = h_{d+i+1} - h_{i+1}, \tag{4}$$

and $10(h_{d+i+1}-h_{i+1})=h_{d+i+2}-h_{i+2}$. Multiplying (4) by 10 and adding, yields

$$10^2(h_{d+i} - h_i) = h_{d+i+2} - h_{i+2}.$$

Thus (inductively), for any $q \geqq 1$,

$$10^q(h_{d+i} - h_i) = h_{d+i+q} - h_{i+q}.$$

But since all $h_i<m$, the right hand side (in absolute value) is less than m. If we choose q large enough so that $10^q>m$, this relation could be true only if $h_{d+i}=h_i$. As in the discussion of above, this implies $10^d \equiv 1 \pmod{m}$. But r is the order of 10 modulo m and so from group theory we know that $r \mid d$. Since $d=(u, r)$, it follows that $r=d$ and so $r \mid u$.

From this theorem it is clear that the digits repeat if and only if we moved ahead r digits (or some multiple of r digits). That is to say, all fractions h_1/m have periods of length precisely r, where r is the order of 10 modulo m.

Note that when m is prime, $\phi(m)=m-1$. Thus when m is prime, $r \mid m-1$.

We now discuss the case of even period r.

LEMMA 1. *If there exists a positive integer v such that $10^v \equiv -1 \pmod{m}$, then r is even, where r is the order of 10 modulo m.*

Proof. Since $10^{2v} \equiv 1 \pmod{m}$ and r is the period of 10 modulo m, we know that $r \mid 2v$. If r were odd then $r \mid v$ and thus $10^v \equiv 1 \pmod{m}$. But from $10^v \equiv -1 \pmod{m}$ we would then get $0 \equiv 2 \pmod{m}$, which is impossible (since we are assuming $(m, 10)=1$).

LEMMA 2. *If m is prime and r is even, then $10^{r/2} \equiv -1 \pmod{m}$.*

Proof. Write $r=2w$, then since $10^r \equiv 1 \pmod{m}$ we have $(10^w-1)(10^w+1) \equiv 0 \pmod{m}$. Since m is prime it must divide one or the other of the terms on the left-hand side. But r is the order of 10 and so $10^w \not\equiv 1 \pmod{m}$. Thus m can only divide the second of the two factors, that is $10^w \equiv -1 \pmod{m}$.

We will continue to assume that $r=2w$ and that the period is $a_1 \cdots a_w a_{w+1} \cdots a_{2w}$. Let c and d be the two half-periods, so that $c=a_1 \cdots a_w$ and $d=a_{w+1} \cdots a_{2w}$ (or writing in terms of powers of 10, $c=a_1 10^{w-1}+a_2 10^{w-2} + \cdots + a_w$ and $d=a_{w+1}10^{w-1}+a_{w+2}10^{w-2}+ \cdots + a_{2w}$).

We can now prove Midy's theorem in a very simple way.

THEOREM 2. *If* $r=2w$ *and* $10^w \equiv -1 \pmod{m}$, *then* $c+d=10^w-1=99\cdots 9$.

Proof. From (2) we have $h_{w+1}=10^w h_1-cm$, $h_{2w+1}=10^w h_{w+1}-dm$. But $r=2w$ is the period, so $h_{2w+1}=h_1$ and thus

$$(h_1 + h_{w+1})(10^w - 1) = (c + d)m. \tag{5}$$

But by hypothesis $10^w-1\equiv -2 \pmod{m}$, so 10^w-1 and m are relatively prime. From (5) we therefore have that $m \mid h_1+h_{w+1}$. But each $h_i<m$ so $h_1+h_{w+1}<2m$. It can therefore be divisible by m only if it equals m, that is, $h_1+h_{w+1}=m$. Hence $c+d=10^w-1$.

Notice that, once again, this theorem depends only on the denominator m of the fraction. Let us say that an integer m which satisfies Theorem 2 has the *nines-property*. From Lemma 2, it immediately follows that:

COROLLARY 1. *Every prime with even period has the nines-property.*

However, it is also true, as the following corollary shows, that there are many composite numbers with the nines-property.

COROLLARY 2. *If* $m \mid (10^p+1)$ *where* p *is prime, then* m *has the nines-property.*

Proof. By hypothesis, $10^p\equiv -1 \pmod{m}$ and so $10^{2p}\equiv 1 \pmod{m}$. Since r is the order of 10 modulo m, it follows that $r \mid 2p$. If $r \mid 2$ then $m \mid 99$. But we always have $10^p\equiv 1 \pmod 3$ and so $10^p \not\equiv -1 \pmod 3$. Since $10^p\equiv -1 \pmod{m}$, it follows that m and 3 are relatively prime. Thus in this case we could only have $m=11$, and it is easily verified directly that $m=11$ satisfies Theorem 2.

The remaining cases are $r=p$, which (as we saw in the proof of Lemma 1) contradicts $10^p\equiv -1 \pmod{m}$ or $r=2p$. In the latter case, Theorem 2 is evidently satisfied.

From this corollary, it follows that there are many composite nines-numbers. For example $10^3+1=7\cdot 11\cdot 13$ so that in addition to primes 7, 11, and 13 we also have composites 77, 91, and 143 (as well as 1001 itself) as nines-numbers.

COROLLARY 3. *If* m *is prime and* $10^{(m-1)/2}\equiv -1 \pmod{m}$ *then* m *is a nines-number.*

Proof. By Lemma 1, r is even and so by Corollary 1, m is a nines-number.

This corollary, together with the theory of quadratic residues, shows that any prime of form $40k \pm 7, \pm 11, \pm 17$, or ± 19 is a nines-number. (For a discussion of quadratic residues see, for example, [2, Chapter 5]. The condition $10^{(m-1)/2}\equiv -1 \pmod{m}$ is the so-called Euler criterion that 10 should be a quadratic nonresidue of the prime m [2, p. 46]. A determination of the form given for the primes for which 10 is a quadratic non-residue is found, as an example, in [2, p. 74].)

On the other hand, there are many primes m with odd periods. If, for example, $(m-1)/2$ is odd and $10^{(m-1)/2}\equiv 1 \pmod{m}$, then clearly r is odd, since it

must divide $(m-1)/2$. Again from the theory of quadratic residues, this class will contain all primes of form $40k+3$, -13, -9, or -1.

Note that Corollary 3 does not give all prime nines-numbers. One such prime which escapes Corollary 3 is 13.

Another familiar class of numbers, the Fermat numbers $m=2^{2^n}+1$, are covered by the following:

COROLLARY 4. *Every prime Fermat number* >5 *is a nines-number.*

Proof. This can be established directly, or one can use a simple induction to show that when $n \geqq 2$, $2^{2^n} \equiv 16 \pmod{40}$. The result is thus a special case of the remark following Corollary 3. This class is, of course, somewhat restricted since the only Fermat primes known which are >5 are given by $n=2$, 3, or 4.

This paper was presented at the May, 1965 meeting of the Nebraska Section of the Mathematical Association of America.

AN INTEGRATED MODEL FOR EUCLIDEAN AND NON-EUCLIDEAN GEOMETRIES

L. G. NOVOA, University of Alabama

1. Introduction. The usual geometric models for non-Euclidean geometries are specifically designed either for hyperbolic geometry (Poincaré, Cayley-Klein, etc.) or for elliptic geometry (bundle and spherical models).

In this paper, we present models which are constructed by using essentially the same idea for all three types of classical two dimensional geometries: hyperbolic, elliptic and Euclidean.

We consider first a set Γ whose elements are certain ellipses in three dimensional Euclidean space, introduce a suitable definition of distance, and show that in a class of subspaces the metric gives rise, quite naturally, to the different types of geometries.

2. The metric space (Γ, δ). Consider the system of quadrics in E^3 with cartesian coordinates X, Y, Z:

$$X^2 + Y^2 - kZ^2 = 1 \quad \text{for all real values of } k. \tag{1}$$

Let these surfaces be intersected by planes which pass through the origin but do not contain the axis OZ. We shall be interested only in those intersections which are ellipses.

To the family Γ of all such ellipses we give a metric structure in the following way.

Let γ be an ellipse of Γ. We project it on the cylinder C: $X^2+Y^2=1$ axially with respect to OZ. This means that to every point P of γ we assign the intersection P' of the line perpendicular to OZ and passing through P, with the cylinder. This gives a closed curve γ' on the cylinder. Let Γ' be the family of all γ'.

In cylindrical coordinates (r, θ, Z) the equation of the cylinder is $r=1$, and θ, Z can be considered as coordinates of a point on the cylinder.

Let the ellipse γ be the intersection of the quadric of parameter k with the plane $Z=mX\cos\theta_0+mY\sin\theta_0$. Then the equation of the curve γ' on the cylinder is:

$$Z=\frac{m\cos(\theta-\theta_0)}{\sqrt{[1-km^2\cos^2(\theta-\theta_0)]}},\qquad \left(\text{if } k>0, \text{ then } |m|<\frac{1}{\sqrt{k}}\right).$$

Two different ellipses of Γ have different projections on C, as can be easily checked. To each system of values for k, m, θ_0 there correspond a definite γ and, also, a definite γ'. If k, m, θ_0 are fixed, then Z in (1) becomes a function of θ: $\phi(\theta)$. Let $\phi_1(\theta)$ and $\phi_2(\theta)$ represent the functions corresponding to two ellipses γ_1, γ_2 of Γ. We define the distance $\delta(\gamma_1, \gamma_2)$ by:

$$\delta(\gamma_1,\gamma_2)=\frac{1}{2}\int_0^{\pi}|\phi_1(\theta)-\phi_2(\theta)|\,d\theta. \tag{2}$$

It is well known from the theory of function spaces that this definition gives a metric structure to the set Γ' and hence to Γ. We designate by (Γ, δ) the metric space thus generated.

3. The subspaces for constant k. We now study the two dimensional subspaces of (Γ, δ) obtained by giving a fixed value to k. There are three different types, depending on whether $k>0$, $k<0$, or $k=0$. The point Q of Γ for which $m=0$ belongs to all of them. We call Q the origin of Γ and it is the circle common to all quadrics of (1).

Straightforward computation gives for the integral: $I=\int_\alpha^{\alpha+\pi}\phi(\theta)\,d\theta$, where $\phi(\theta)=[m\cos(\theta-\theta_0)]/\sqrt{[1-km^2\cos^2(\theta-\theta_0)]}$, the values:

$$\begin{cases} I=-\dfrac{2}{\sqrt{k}}\sinh^{-1}\dfrac{m\sin(\alpha-\theta_0)}{\sqrt{[k^{-1}-m^2]}} & \text{for } k>0,\\[2ex] I=-\dfrac{2}{\sqrt{-k}}\sin^{-1}\dfrac{m\sin(\alpha-\theta_0)}{\sqrt{[m^2-k^{-1}]}} & \text{for } k<0,\\[2ex] I=-2m\sin(\alpha-\theta_0) & \text{for } k=0. \end{cases} \tag{3}$$

To compute the distance between two points (m_1, θ_1) and (m_2, θ_2), for some

subspace, we use the periodic properties of ϕ and put:

$$2\delta(\gamma_1, \gamma_2) = \int_0^{\pi} |\phi_1 - \phi_2| \, d\theta = \left| \int_{\alpha_0}^{\alpha_0+\pi} (\phi_1 - \phi_2) d\theta \right| ,$$

where α_0 is the value of θ for one of the common points of γ_1' and γ_2' on the cylinder i.e.: $\phi_1(\alpha_0) = \phi_2(\alpha_0)$. This implies that:

$$m_1 \cos(\alpha_0 - \theta_1) = m_2 \cos(\alpha_0 - \theta_2). \tag{4}$$

If $k > 0$ we use (3) to obtain

$$\delta(\gamma_1, \gamma_2) = \frac{1}{\sqrt{k}} \left| \sinh^{-1} \frac{m_1 \sin(\alpha_0 - \theta_1)}{\sqrt{[k^{-1} - m_1^2]}} - \sinh^{-1} \frac{m_2 \sin(\alpha_0 - \theta_2)}{\sqrt{[k^{-1} - m_2^2]}} \right| ;$$

calling $R = 1/\sqrt{|k|}$, taking the hyperbolic cosine of both sides, and using (4), we get

$$\cosh \frac{\delta}{R} = \frac{R^2 - m_1 m_2 \cos(\theta_1 - \theta_2)}{\sqrt{[R^2 - m_1^2]}\sqrt{[R^2 - m_2^2]}} . \tag{5}$$

The distance ρ from γ to the origin is: $\cosh \rho/R = R/\sqrt{[R^2 - m^2]}$. If we take the number ρ as a coordinate (instead of m) formula (5) becomes:

$$\cosh \frac{\delta}{R} = \cosh \frac{\rho_1}{R} \cosh \frac{\rho_2}{R} - \sinh \frac{\rho_1}{R} \sinh \frac{\rho_2}{R} \cos(\theta_1 - \theta_2), \tag{6}$$

which is the standard formula for the distance in hyperbolic geometry when we take hyperbolic polar coordinates (ρ, θ).

A similar analysis for the case $k < 0$ gives for the distance:

$$\cos \frac{\delta}{R} = \cos \frac{\rho_1}{R} \cos \frac{\rho_2}{R} + \sin \frac{\rho_1}{R} \sin \frac{\rho_2}{R} \cos(\theta_1 - \theta_2) \tag{7}$$

which again is the well-known formula for the distance in spherical geometry when we take polar coordinates (ρ, θ).

Finally if $k = 0$ then $\delta = m_1 \sin(\alpha_0 - \theta_1) - m_2 \sin(\alpha_0 - \theta_2)$, from which, squaring and using (4), we get: $\delta^2 = m_1^2 + m_2^2 - 2m_1 m_2 \cos(\theta_1 - \theta_2)$. Since m represents, in this case, the distance ρ to the origin we have:

$$\delta^2 = \rho_1^2 + \rho_2^2 - 2\rho_1\rho_2 \cos(\theta_1 - \theta_2)$$

which is the distance in polar coordinates in the Euclidean plane.

In summary, the subspaces with $k > 0$ are hyperbolic planes, those with $k < 0$ are spherical regions (in fact half-spheres) and for $k = 0$ we get a Euclidean plane.

It is interesting to note that the intersections which are not ellipses, and which exist if $k \geqq 0$, can be identified in a rather natural way with the ideal and ultra-ideal points of the euclidean and hyperbolic planes.

4. The case $k<0$. In this case the quadric of (1) is the ellipsoid σ:

$$X^2 + Y^2 + \frac{Z^2}{R^2} = 1, \qquad \text{where } R = \frac{1}{\sqrt{|k|}}$$

and ρ, as defined above, is properly bounded by $(\pi/2)R$. Hence the corresponding 2-dimensional subspace S is isometric to an open half-sphere with the metric defined by (7). To pass from S to an elliptic plane we have to add the intersections γ^* of σ with the planes through OZ, which were omitted at the beginning, and redefine the distance in the usual way:

$$\delta' = \text{Min } (\delta, \pi R - \delta). \tag{8}$$

This process will add to the half-sphere mentioned above its boundary: $\rho=(\pi/2)R$ and at the same time will identify antipodal points, if we agree that $\delta'(P, Q)=0$ means $P=Q$.

Since the axial projections of "vertical" ellipses (those which pass through OZ) on the cylinder are not well defined, we agree to associate to each such ellipse γ^*, determined by the plane $\theta=\theta_0$, the function ϕ_{γ^*} defined as follows:

$$\phi_{\gamma^*} = -\frac{\pi}{2}R \quad \text{for } 0 \leqq \theta \leqq \theta_0$$

and

$$\phi_{\gamma^*} = \frac{\pi}{2}R \quad \text{for } \theta_0 < \theta \leqq \pi.$$

Call S' the set of vertical ellipses. The set $P=S\cup S'$ is a metric space as soon as we extend the definition of distance of paragraph 2 to the new elements γ^* and the associated functions ϕ_{γ^*}.

Finally, the redefinition (8) will make P into an elliptic plane. We leave the details to the reader, since they are similar to the usual procedure to pass from the metric 2-sphere to the elliptic plane.

When $k=-1$, the geometric meaning of definition (2) becomes particularly clear. In this case, the quadric becomes a sphere, and the axial projection of this sphere on the cylinder is area-preserving. Hence, the integral of (2) is proportional to one of the areas intercepted, on the sphere, by two great circles. The convention (8) means that δ' is proportional to the smaller of the two angles formed by the great circles. In other words, the metric δ' is equivalent to the angular metric of spherical geometry, which is, in turn, equivalent to the metric of the elliptic plane.

5. Geodesics. It is not difficult to see that, for a fixed k, the set of intersections of a family of planes which contain a fixed line l through O, with the corresponding quadric, constitutes a set of points of Γ, which is isometric to a circle if $k<0$ or to a straight line if $k\geqq 0$, and represents, therefore, a geodesic of Γ.

To every such geodesic we can associate the pair of points L_1, L_2, in which l meets the quadric, and which are common to all the intersections. Conversely, all the geodesics of the subspace $k=$constant can be obtained in this way.

This means that the lines (geodesics) of the Euclidean or non-Euclidean planes, considered in the preceding sections, can be identified with pairs of points, symmetric with respect to O, and contained in the corresponding quadric.

A BARRIER FUNCTION FOR THE ORIGIN OF A CONCAVE n-DIMENSIONAL HYPERSPHERICAL SECTOR

R. A. FRISCH, General Cable Corporation's Research Laboratories, Bayonne, N.J.

In the study of partial differential equations in an n-dimensional space ($n\geqq 2$, integer), the concept of a barrier function has been widely used to guarantee continuity of the solution of a partial differential equation on the boundary of the domain in which the equation is defined [1, pp. 168 *et seq.*]. A barrier function can be defined as follows:

Let the partial differential equation be defined in a domain G with boundary G' and closure $\overline{G}$. Let $Q\in G'$ be a point of the boundary, let $N_Q\in\overline{G}$ be a neighborhood of Q and let $P\in N_Q$ ($P\neq Q$) be a generic point of N_Q. A barrier function B for the point Q will have the following properties:

(i) B is defined, continuous, and singlevalued in N_Q and on its boundary;

(ii) $B(Q)=0$;

(iii) $B(P)>0$;

(iv) B is superharmonic in N_Q.

The existence of a barrier at a point Q guarantees the continuity of the solution f of the given partial differential equation at Q [1, 184 *et seq.*], and therefore the existence of a barrier function at every point of G' guarantees the continuity of f at the boundary.

The barrier function for the origin of a convex n-dimensional hyperspherical sector of radius R is well known [1, 187]. For the origin of a concave sector, however, proof of existence of a barrier for $n\geqq 3$ has rested on the exclusion from the sector of another origin-centered sector of radius r, $r<R$, and on letting r tend to zero [1, 187]. In the following a barrier is constructed for this origin, thus avoiding the use of a limiting process.

In an n-dimensional space with Cartesian coordinates x_i, $i=1, 2, \cdots, n$, $n\geqq 3$, let there be defined the two functions

$$r^2=\sum_{i=1}^{n}x_i^2 \qquad r\geqq 0, \tag{1}$$

$$\phi=\arccos(x_n/r) \qquad 0\leqq\phi\leqq\pi. \tag{2}$$

In this space, an origin-centered hyperspherical concave sector is defined by

$$0 < r < R \qquad R \text{ finite}, \tag{3}$$

$$0 \leqq \phi < \theta \qquad \pi/2 < \theta < \pi. \tag{4}$$

This sector, which we call S, is a domain. Let S' be the boundary of S and let $\overline{S} = S \cup S'$.

Consider the function

$$F = r^{1-\alpha} \cos \phi/k. \tag{5}$$

If $k>1$ is finite and such that $\phi/k < \pi/2$, and if $\alpha<1$, then F is obviously zero at the origin, positive everywhere else in $\overline{S}$ and continuous on S'.

The Laplacian of F is

$$\Delta F = \sum_{i=1}^{n} \frac{\partial^2 F}{\partial x_i^2} = k^{-2} r^{-\alpha-1} \left\{ \cos \frac{\phi}{k} \left[k^2(n-1-\alpha)(1-\alpha) - 1 \right] - k \sin \frac{\phi}{k} \operatorname{ctg} \phi \right\} . \tag{6}$$

Since $k^{-2}r^{-\alpha-1}>0$ for $k>1$ and finite, $\Delta F \leqq 0$ in S if and when

$$\cos \frac{\phi}{k} \left[1 - k^2(n-1-\alpha)(1-\alpha) \right] + k \sin \frac{\phi}{k} \operatorname{ctg} \phi \geqq 0. \tag{7}$$

Since $\sin \phi/k \geqq 0$ and $\cos \phi/k > 0$ everywhere in S, and since for $\pi/2 < \phi < \pi$, $\operatorname{ctg} \phi < 0$, it follows that

$$1 - k^2(n-1-\alpha)(1-\alpha) > 0 \tag{8}$$

is a necessary condition for the fulfillment of (7). Solution of (8) together with the formerly established condition $\alpha<1$ yields

$$0 < \tfrac{1}{2}\left[n - \sqrt{n^2 - 4(n-1-k^{-2})} \right] < \alpha < 1. \tag{9}$$

It is clear that if (8) is satisfied, (7) will be satisfied for $\phi=0$, for any $k>1$. For other values of ϕ, (7) can be written

$$G(\phi) = \eta\lambda \operatorname{ctg} \lambda\phi + \operatorname{ctg} \phi \geqq 0, \tag{10}$$

$$0 < \eta < 1, \qquad \eta = 1 - k^2(n-1-\alpha)(1-\alpha), \tag{11}$$

$$0 < \lambda < 1, \qquad \lambda = 1/k. \tag{12}$$

Two immediate properties of $G(\phi)$ are: $1-G \geqq 0$ for $0 < \phi \leqq \pi/2$, for any λ and η; $2 - dG/d\phi < 0$ for any λ and η for $0 < \phi < \pi$.

Therefore if for θ of (4), $G(\theta) \geqq 0$, then $G(\phi) > 0$ for $0 < \phi < \theta$.

$G(\theta)$ can be written, using Riemann's Zeta-function, as

$$(13)\qquad \eta\lambda\left[\frac{1}{\lambda\theta}-\sum_{n=1}^{\infty}\frac{2\zeta(2n)}{\pi^{2n}}(\lambda\theta)^{2n-1}\right]>\frac{1}{\pi-\theta}-\sum_{n=1}^{\infty}\frac{2\zeta(2n)}{\pi^{2n}}(\pi-\theta)^{2n-1}.$$

Introducing λ into the bracket, multiplying by $\theta(\pi-\theta)>0$ due to (4), we obtain (13) in the form

$$(14)\qquad \eta(\pi-\theta)-\theta\geqq\sum_{n=1}^{\infty}2\zeta(2n)\left[\eta(\pi-\theta)\left(\frac{\lambda\theta}{\pi}\right)^{2n}-\theta\left(\frac{\pi-\theta}{\pi}\right)^{2n}\right].$$

Since the zeta-function of a real argument larger than one is monotonically decreasing, (14) will be satisfied if

$$(15)\qquad \eta(\pi-\theta)-\theta\geqq A\left[\eta(\pi-\theta)\sum_{n=1}^{\infty}\left(\frac{\lambda\theta}{\pi}\right)^{2n}-\theta\sum_{n=1}^{\infty}\left(\frac{\pi-\theta}{\pi}\right)^{2n}\right],$$

where $A=2\zeta(2)$. The inequality (15) can be written as

$$(16)\qquad \frac{\eta(\pi-\theta)-\theta}{A}+\theta\zeta\left[\left(\frac{\pi}{\pi-\theta}\right)^{2}\right]\geqq\eta(\pi-\theta)\zeta\left[\left(\frac{\pi}{\lambda\theta}\right)^{2}\right]$$

and, since the zeta-function of a real argument larger than one is always larger than one, (16) will be satisfied if

$$(17)\qquad \frac{\eta(\pi-\theta)-\theta}{A}+\theta\geqq\eta(\pi-\theta)\zeta\left[\left(\frac{\pi}{\lambda\theta}\right)^{2}\right].$$

Putting $K\geqq\zeta[(\pi/\lambda\theta)^2]>1$, we see that (17) is satisfied if

$$(18)\qquad 2A\eta K\theta+2A\theta-\theta-\eta\theta\geqq 2A\eta K\pi-\eta\pi.$$

Inequality (18) will be satisfied if

$$(19)\qquad 2A\eta K\theta+2A\theta-\theta-\eta K\theta\geqq 2A\eta K\pi-\eta\pi,$$

or if

$$(20)\qquad \theta\geqq\pi\frac{\eta(2AK-1)}{(2A-1)(1+\eta K)}.$$

Inequality (20) will hold for $\theta\geqq\pi/2$ if

$$(21)\qquad K\leqq\frac{2A-1+2\eta}{\eta(2A+1)}.$$

The right side of (21) being always larger than one for $0<\eta^*<1$, it will always be possible to choose $\epsilon^*>0$ such that $K\geqq 1+\epsilon^*$.

Since $\zeta(x)\to 1$ if $x\to\infty$, there will exist a value $\lambda^*<1$ such that $\zeta[(\pi/\lambda^*\theta)^2]\leqq 1+\epsilon^*$. Thus (11) can be solved for α in terms of η^* and $k^*=1/\lambda^*$. Introducing the solution $\alpha^*<1$, together with k^*, into (7), we see that this inequality will

always be satisfied in S. Therefore $\Delta F \leqq 0$ everywhere in S. Consequently F is also superharmonic in S and constitutes a barrier function for the origin of the hyperspherical sector defined by (3) and (4).

MATHEMATICAL NOTES

A NOTE ON LARGE MEASURABLE SETS

D. M. Topping, Tulane University

1. Purpose. A well-known result in the classical theory of Lebesgue measure describes a measurable set as the disjoint union of a Borel set and a null set. In the Bourbaki theory of integration on locally compact spaces, the question of finding a suitable counterpart to this result for non-σ-finite spaces does not appear to have been adequately answered in the literature.

We shall furnish a simple and natural generalization of the classical situation which, in a sense, is the best possible. The technique used is a slight variation of the old "exhaustion" method in modern transfinite disguise.

2. The setting. We begin with a locally compact Hausdorff space X and a positive integral (or Radon "measure") I, defined on the space of real continuous functions having compact supports. The theory proceeds by extending I to an "upper integral" $\bar{I}$ defined on *all* nonnegative functions on X with values in the interval $[0, +\infty]$. One then obtains a Carathéodory outer measure $\bar{\mu}$ by setting $\bar{\mu}(A) = \bar{I}(\chi_A)$ for each subset A of X, where χ_A is the characteristic function of the set A. The measurable sets can then be defined by the classical inequality of Carathéodory: A is *measurable* if $\bar{\mu}(S) \geqq \bar{\mu}(S \cap A) + \bar{\mu}(S \cap A')$, for all subsets S of X. Tracing through the theory, we find that the measurable sets thus defined are just the sets which are "locally measurable" [1] with respect to the ring of *summable* sets (sets whose characteristic functions are summable—these are precisely the measurable sets A with $\bar{\mu}(A) < +\infty$). For a set to be measurable, it is enough that it intersect every compact set in a summable set. An extremely lucid account of the theory appears in [2] Chapter 3, to which we refer for further details.

By a *Borel* set we shall mean an element of the σ-algebra generated by the open sets of X. Another notion of "Borel set" is in current usage (these are the σ-bounded Borel sets), and Berberian [1] has described very nicely the connections between the two. A *locally Borel* set is a subset of X which intersects each compact set in a Borel set. It is easily seen that a subset of X is locally Borel if and only if it meets each σ-bounded Borel set in a Borel set. A *locally*

null set is a subset N of X such that $\mu(N\cap K)=0$ for each compact subset K of X [2] (esp. pp. 124–130, 136 and 228). It is clear that locally Borel and locally null sets are measurable.

3. The decomposition. In the setting described above, our observation can now be stated. The σ-finite case is, of course, classical.

THEOREM. *Let A be measurable (and non-σ-finite). Then there is a family $\mathfrak{A}$ of pairwise disjoint compact sets, each contained in A, such that:*

(1) $\mu(U\cap K)>0$ *if U is open, $K\in\mathfrak{A}$ and $U\cap K\neq\varnothing$.*

(2) $B=\bigcup\{K:K\in\mathfrak{A}\}$ *is locally Borel.*

(3) $N=A-B$ *is locally null.*

(4) *Each open set of finite positive outer measure meets only countably many of the sets in $\mathfrak{A}$.*

Proof. The empty family satisfies (1) vacuously and Zorn's lemma shows that there is a maximal family $\mathfrak{A}$ of pairwise disjoint compact subsets of X, each contained in A, satisfying (1). Property (4) follows immediately from (1).

If C is a compact subset of X, then C meets only countably many of the sets in $\mathfrak{A}$, say $\{K_n:n=1,\ 2,\ \cdots\}$. Now $B\cap C=\bigcup\{K_n\cap C:n=1,\ 2,\ \cdots\}$ which is manifestly a Borel set. Thus B is locally Borel, and it follows that N is measurable. The proof that N is locally null proceeds exactly as in [2] ((11.39), p. 129).

REMARK. The set B in the theorem might be called a "locally Borel kernel" of A. Applying the construction to $X-A$, one obtains a "locally Borel cover," i.e., a locally Borel set $E\supset A$ with $E-A$ locally null.

4. An example. It is natural to ask if the set B in part (2) of the theorem can be taken to be a Borel set (clearly Borel sets are locally Borel). In special cases (apart from the classical σ-compact situation), the locally Borel sets will coincide with the Borel sets, e.g., when X is uncountable and discrete.

Perhaps the best "large" locally compact spaces for integration theory are the paracompact spaces, which include, for example, locally compact groups (such spaces are known to be the disjoint union of open σ-compact subspaces). Even here, however, locally Borel and Borel sets need not coincide, as shown by a simple example, essentially due to Kuratowski ([3] bottom of p. 268). Take X to be the product of a discrete real line with the usual real line. (Kuratowski uses $[0,\ 1]\times\Omega$, with Ω discrete, but this is an unimportant modification.) Kuratowski's argument shows that there are locally Borel sets in X which are not Borel sets, (this example was discovered independently by R. G. Douglas in conversation with the author). Moreover, X is a metrisable abelian group (hence paracompact), and with Haar measure (see [2] (11.33), p. 127) it is easily seen that our theorem gives the sharpest description of measurable sets that general circumstances will permit.

In case our space is a locally compact group, a sharper analysis can be made. The result below was noted in conversation with M. A. Moskowitz. For sim-

plicity, we assume that our group G is a (not necessarily connected) Lie group, but a standard approximation argument can be used to extend the theorem to the locally compact case.

THEOREM 2. *Locally Borel sets in G are Borel sets if and only if G is either σ-compact or zero-dimensional (i.e. discrete).*

Proof. If U is a symmetric neighborhood of the identity with compact closure, then $G_0=\bigcup_{n=1}^{\infty}\overline{U}^n$ is a σ-compact subgroup, which we may assume to be connected.

Assume now that G is neither σ-compact nor zero-dimensional. Since G_0 is locally Euclidean and not zero-dimensional, it contains a Borel set B_α of each class $\alpha<\Omega$. Well-order the cosets of G_0. Then, by assumption, there are *at least* Ω ordinals used in the well-ordering (otherwise G would be σ-compact). Choose a Borel set B_α of class $\alpha<\Omega$ from the α-th coset of G_0. Then as in Kuratowski's example, $\bigcup_{\alpha<\Omega}B_\alpha$ is locally a Borel set, but not a Borel set. The reverse implication is clear.

Berberian has recently communicated a related result (to appear in the MONTHLY): Haar measure on the Borel sets (as defined in section 2 above) of a locally compact group G is simultaneously inner and outer regular if and only if G is either σ-compact or discrete.

A NONLINEAR GENERALIZATION OF A THEOREM ON FUNCTION ALGEBRAS

S. CATER, Portland State College

In this paper X will be a compact Hausdorff space, $C(X)$ will denote the algebra of all continuous real valued functions on X, and $D(X)$ will denote the family of all continuous functions from X to the interval $[0, 1]$. From the work of R. I. Jewett [1] we infer immediately the following variation of the Stone-Weierstrass Theorem.

PROPOSITION 1. *Let L be a nonvoid uniformly closed point separating subset of $D(X)$ satisfying*

(i) *if $f, g\in L$, then $fg\in L$,*

(ii) *if $f\in L$, then $1-f\in L$.*

Then there exists a (possibly void) totally disconnected closed subset E of X such that L consists of all the functions $f\in D(X)$ for which $f(E)$ is a subset of the doubleton $\{0, 1\}$.

This work inspires a nonlinear generalization of some well-known results on function algebras (for example, see [2], pp. 245–6) which we hope is of some intrinsic interest. We present

THEOREM 1. *Let L be as in Proposition* 1 *and let u be a mapping of L into the interval* $[0, 1]$ *satisfying*

(1) $u(fg)=u(f)u(g)$ *for each* $f, g\in L$,

(2) $u(1-f)=1-u(f)$ *for each* $f\in L$.

Then there exists a unique point $x_0\in X$ *such that* $u(f)=f(x_0)$ *for each* $f\in L$.

From this we can establish immediately

THEOREM 2. *Let L be as above and let Y be another compact Hausdorff space. Suppose ϕ is a mapping of L into $D(Y)$ satisfying* (1) *and* (2). *Then there exists a continuous mapping p of Y into X such that $\phi(f)(y)=f(py)$ for each $f\in L$, $y\in Y$.*

In [3] Milgram provides a result related to Theorem 2 which describes all the isomorphisms ϕ of the multiplicative semi-group $C(X)$ onto $C(Y)$; given ϕ there exists a homeomorphism T of Y onto X and for each $x\in X$ there exists a multiplicative mapping p_x of the real line onto itself for which

$$\phi(f)(y) = p_{Ty}[f(Ty)] \quad \text{for each } f \in C(X),\ y \in Y.$$

In [3] it is essential, however, that ϕ be a 1-1 mapping of $C(X)$ onto $C(Y)$, and functions in $C(X)-D(X)$ are required in the arguments (see Example 1). For more on multiplicative transformations see Bourgin [4] and [5].

Proof of Theorem 1. Either $u(L)$ is the doubleton $\{0, 1\}$ or else $u(L)$ contains a number $\neq 0$ or 1. We begin with the trivial case in which u takes only the values 0 and 1.

Let $f\in L$ such that $u(f)=1$. Then $1\in f(X)$; for otherwise there would exist an integer n such that $f^n<\frac{1}{2}<1-f^n$, $u(f^n)=u(f)^n=1$ and $u(1-f^n)=0$. But $f^n(1-f^n)^{-1}\in L$ and $u(f^n)=u(1-f^n)u[f^n(1-f^n)^{-1}]=0$, which is impossible.

Now suppose that $f_1 \cdots, f_m$ are finitely many functions in L which satisfy $u(f_i)=1$ for each i. Then $u(f_1 \cdots f_m)=u(f_1) \cdots u(f_m)=1$ and it follows that there exists a nonvoid compact set K such that $(f_1 \cdots f_m)(K)=f_i(K)=1$ for each i. Sets of the form $X(f=1)$, where $u(f)=1$, have the finite intersection property. By the compactness of X, there exists a nonvoid subset S of X such that $f(S)=1$ for each $f\in L$ satisfying $u(f)=1$. By (2) we have $f(S)=0$ for each $f\in L$ satisfying $u(f)=0$. Since L separates points in X, S must consist of just one point x_0. Hence $u(f)=f(x_0)$ for each $f\in L$ and the proof is complete if u takes only the values 0 and 1.

Now assume that there exists an $f\in L$ such that $0<u(f)<1$. By (1) we have $f^h\in L$ and $u(f^h)=u(f)^h$ for any positive rational number h. If h and j are positive rational numbers and k is a positive real number such that $j<k<h$, then $f^{k-j}\in L$, $f^{h-k}\in L$, $f^k\in L$, and

$$u(f)^h = u(f^h) = u(f^{h-k})u(f^k) \leqq u(f^k) = u(f^{k-j})u(f^j) \leqq u(f^j) = u(f)^j.$$

It follows that $u(f^k)=u(f)^k$ for any positive number k.

Let $f_1, \cdots, f_n$ be finitely many functions in L satisfying $0<u(f_i)<1$ for each i. Let k_i be the positive number for which $u(f_i)^{k_i}=\frac{1}{2}$ for each i, and let k be the positive number for which $3^k=\frac{1}{2}(4^k)$. Set

$$f=[1-f_1^{k_1}(1-f_1^{k_1})]^{k/n}[1-f_2^{k_2}(1-f_2^{k_2})]^{k/n}\cdots[1-f_n^{k_n}(1-f_n^{k_n})]^{k/n}.$$

From the preceding paragraph we get $f\in L$ and $u(f)=\frac{1}{2}$. Furthermore, $(1-r(1-r))^k\geqq\frac{1}{2}$ for any real number r, and equality holds if and only if $r=\frac{1}{2}$. Hence $f\geqq\frac{1}{2}\geqq 1-f$. We claim that the strict inequality $f>1-f$ cannot hold. For, if it did, there would be a number $j>1$ such that $f^j>1-f$ and $u(f^j)=u(f)^j=(\frac{1}{2})^j<\frac{1}{2}=u(1-f)$; but $f^{-j}(1-f)\in L$, and $u(1-f)=u(f^j)u[f^{-j}(1-f)]\leqq u(f^j)$, which is impossible. Hence there is a nonvoid compact subset C of X such that $f(C)=\frac{1}{2}$. It follows that $f_i^{k_i}(C)=\frac{1}{2}=u(f_i)^{k_i}$ and $f_i(C)=u(f_i)$ for each i. The compact subsets of the form $X(f=u(f))$, where $f\in L$ and $0<u(f)<1$, have the finite intersection property. By the compactness of X, there exists a nonvoid set S such that $f(S)=u(f)$ for each $f\in L$ satisfying $0<u(f)<1$.

We claim that $f(S)=u(f)$ for any $f\in L$. Suppose that $u(f)=1$. Select $g\in L$ such that $0<u(g)<1$. Then $0<u(fg)=u(g)<1$, and we have $(fg)(S)=u(fg)=u(g)=g(S)$. Hence $f(S)=1$. By (2) we also get $f(S)=0$ if $u(f)=0$. Of course, the set S consists of just one point because L separates points in X. This completes the proof of Theorem 1.

Proof of Theorem 2. Select $y\in Y$ and define $u(f)=\phi(f)(y)$ for each $f\in L$. Then u is a mapping of L into $[0, 1]$ satisfying (1) and (2). By Theorem 1 there is a point $y^*\in X$ such that $u(f)=f(y^*)$ for each $f\in L$. We need only make $py=y^*$. To show that p is continuous is routine; note that if U is a neighborhood of py in X, then there exists an $f\in L$ such that $f(py)=1$, $f(X-U)=0$, and $p[Y(\phi(f)>0)]\subset U$, $y\in Y(\phi(f)>0)$.

We now present examples which show that neither (1) nor (2) can be omitted from Theorem 2.

Example 1. Let N be the set of positive integers under the discrete topology and let X be the Stone-Čech compactification of N. Note that any bounded function on N extends to a unique continuous function on X. For each $f\in D(X)$, let $\phi(f)$ be the function in $D(X)$ for which $\phi(f)(n)=[f(n)]^n$ for $n\in N$. Then ϕ is obviously a 1-1 multiplicative mapping of $D(X)$ onto $D(X)$. But $\phi(\frac{1}{2})=0$ on $X-N$ and $\phi^{-1}(\frac{1}{2})=1$ on $X-N$. Since $\phi(0)=0$ and $\phi(1)=1$, it is clear that neither ϕ nor ϕ^{-1} can be implemented by a continuous mapping of X into X. Hence (2) cannot be omitted from Theorem 2.

Example 2. Let N and X be the same as in Example 1. For each positive integer n let p_n be the mapping of the unit interval into itself defined in the following way; $p_n(r)=2^n r^{n+1}$ for $0\leqq r\leqq\frac{1}{2}$, and $p_n(r)=1-p_n(1-r)$ for $\frac{1}{2}<r\leqq 1$. For each $f\in D(X)$, let $\phi(f)$ be the function in $D(X)$ for which $\phi(f)(n)=p_n[f(n)]$, each $n\in N$. Then ϕ is a 1-1 mapping of $D(X)$ onto $D(X)$ which satisfies (2). But $\phi(\frac{1}{4})=0$ on $X-N$ and $\phi^{-1}(\frac{1}{4})=\frac{1}{2}$ on $X-N$. Since $\phi(0)=0$ and $\phi^{-1}(\frac{1}{2})=\frac{1}{2}$ it

is clear that neither ϕ nor ϕ^{-1} can be implemented by a continuous mapping of X into X. Hence (1) cannot be omitted from Theorem 2.

We conclude with one further comment. Milgram [3] showed that the multiplicative semi-group $C(X)$ characterizes a compact space X. By replacing $C(X)$ with $D(X)$ in Theorem 3.1 and in the preceding work in [3] we see that the multiplicative semi-group $D(X)$ also characterizes a compact space X. Functions exceeding 1 are not needed in this portion of Milgram's arguments.

ON SIMPLE RINGS WITH UNIFORM RIGHT IDEALS

KWANGIL KOH, North Carolina State University

If R is a ring, a right ideal I of R is said to be *a complement right ideal* of R provided that there exists a right ideal K in R such that $I \wedge K = (0)$ and if J is a right ideal such that $J > I$ then $J \wedge K \neq (0)$. A right ideal U of R is said to be *uniform* if any pair of nonzero right ideals of R, which are contained in R, has a nonzero intersection. A ring R is *a right Ore domain* if R is a uniform right ideal and R contains no divisors of zero. In [1], C. Faith proved that if R is a simple ring with identity which contains a minimal complement right ideal, then R is the endomorphism ring of a unital torsion-free module over an integral domain. In proving the theorem cited above, he used a theorem of Utumi [5], viz., the maximal right quotient ring S of R is a full ring of linear transformations in a right vector space over a field D.

The purpose of this note is to give an elementary proof of Faith's theorem without using Utumi's result.

LEMMA. *Let R be a prime ring with 1 such that the right singular ideal of R is zero. If R contains a uniform right ideal U, then for each $u \in U$, $u \neq 0$, $\mathrm{Hom}_R(uR, uR)$ is a right Ore domain.*

Proof. Let $(u)^r = \{r \in R \mid ur = 0\}$. Then $(u)^r$ is a maximal annihilator right ideal of R by [4; 4.11]. Define $N = \{r \in R \mid r(u)^r \leqq (u)^r\}$ and $K = N/(u)^r$. By [2; Theorem 1, p. 25], $K \cong \mathrm{Hom}_R(uR, uR)$. Let $k_1, k_2 \in K$ such that $k_i = n_i + (u)^r$ for some $n_i \in N$, $n_i \notin (u)^r$, $i = 1, 2$. If $k_1 k_2 = 0$ then $n_1 n_2 \in (u)^r$ and $(un_1)^r > (u)^r$ since $n_i(u)^r \leqq (u)^r$ and $n_2 \in (un_1)^r$ but $n_2 \notin (u)^r$. This is impossible since $(u)^r$ is a maximal annihilator right ideal. Hence K is an integral domain. Let $J = (n_1R + (u)^r) \wedge (n_2R + (u)^r)$. Then $J > (u)^r$ since $uR \cong R/(u)^r$ and uR is a uni-

form right ideal of R. Since $(uJ)(uJ)\neq(0)$, we can choose $j\in J$ such that $uju\neq 0$. $ju\in N\wedge J$ and $ju\notin(u)^r$ since $u(ju)(u)^r=(0)$ and $uju\neq 0$. There exist r_1, $r_2\in R$ with r_1, $r_2\notin(u)^r$ and a_1, $a_2\in(u)^r$ such that $ju=n_1r_1+a_1=n_2r_2+a_2$. Hence $n_ir_i=ju-a_i\in N$ for $i=1$, 2. Now $n_ir_i(u)^r\leqq(u)^r$ for all $i=1$, 2, hence if r_1 or $r_2\notin N$, say $r_1\notin N$ then $(un_1)^r>(u)^r$. This follows from the fact that $r_1(u)^r$ is not a subset of $(u)^r$ and $u(n_1r_1)(u)^r=(0)$. This is impossible since $un_1\neq 0$ and $(u)^r$ is a maximal annihilator right ideal of R. This proves that K is a right Ore domain.

THEOREM. *If R is a simple ring with identity which contains a uniform right ideal U, then there exists a left ideal L in R and a right Ore-domain K such that L is a unital torsion-free right K-module and $R\cong\mathrm{Hom}_K(L, L)$.*

Proof. By lemma, $K=\mathrm{N}/(u)^r\cong\mathrm{Hom}_R(uR, uR)$ is a right Ore-domain. Let $L=\{r\in R\,|\,r(u)^r=(0)\}$. Define $l\cdot(n+(u)^r=ln$ for all $l\in L$ and $n+(u)^r\in K$, where $n\in N$. Since $ln(u)^r=(0)$, L becomes a right K-module under this definition. If $x\in L$ and $x\neq 0$ then $(x)^r=(u)^r$ since $x(u)^r=(0)$ and $(u)^r$ is a maximal annihilator right ideal of R. Hence, if $xn=0$ for some $n\in N$ then $n\in(u)^r$. Thus L is a torsion-free K-module. Define a mapping f from R into $\mathrm{Hom}_K(L, L)$ by $f(r)(l)=rl$ for all $l\in L$. It is easy to see that f is a ring homorphism of R into $\mathrm{Hom}_K(L, L)$. The kernel of f is zero since $L^l=\{r\in R\,|\,rL=(0)\}=(0)$. Let $t\in\mathrm{Hom}_K(L, L)$ and $l\in L$. Since $1\in R=LR$, $1=\sum_{i=1}^n l_ir_i$ for some $l_i\in L$, $r_i\in R$ and some positive integer n.

$$t(l)=t(1l)=t\left(\sum_{i=1}^n l_ir_il\right)=\sum_{i=1}^n t(l_i)r_il$$

since t is a K-homomorphism and $r_il\in N$ for all $1\leqq i\leqq n$. Let $\bar{l}_i=t(l_i)$, then

$$t(l)=\left(\sum_{i=1}^n \bar{l}_ir_i\right)l \quad\text{and}\quad t=f\left(\sum_{i=1}^n \bar{l}_ir_i\right).$$

This proves that $R\cong\mathrm{Hom}_K(L, L)$.

REMARK. If R is a simple ring with 1 which contains a uniform right ideal U then $\hat{R}$, the maximal right quotient ring of R in the sense of [3], is a simple ring with a minimal right ideal with 1. By [2; Structure Theorem, p. 75], $\hat{R}$ is isomorphic to the set of all linear transformations of finite rank of a vector space M over a division ring Δ and since $1\in\hat{R}$, $\hat{R}$ is isomorphic to the ring of all linear transformations of the finite dimensional vector space M over Δ. Hence $\hat{R}$ is a simple ring with minimum conditions on one-sided ideals. It is easy to check that $\mathrm{Hom}_R(uR, uR)$ is isomorphic to a subring of $\mathrm{Hom}_{\hat{R}}(u\hat{R}, u\hat{R})=D$ which is a division ring. Furthermore, if we let $(\bar{u})^r=\{x\in\hat{R}\,|\,ux=0\}$ and $\bar{L}=\{x\in\hat{R}\,|\,x(\bar{u})^r=(0)\}$ then $\hat{R}\cong\mathrm{Hom}_D(\bar{L}, \bar{L})$.

ON A SEMI-PRIME SELF INJECTIVE RING

KWANGIL KOH, North Carolina State University

1. The purpose of this note is to prove that if a ring R with 1 is *semi-prime* [2] and *right self injective* [6] then every maximal annihilator right ideal (if it exists) is a maximal right ideal which is generated by an idempotent in R. If $a\in R$ such that $(a)^r=\{r\in R\,|\,ar=0\}$ has a nonzero intersection with each nonzero right ideal of R then a is called a right singular element of R. The set of all right singular elements in R will be denoted by R_r^Δ. R_r^Δ is a two sided ideal of R and it is called the *right singular ideal* of R [4]. In the sequel, R will denote a semi-prime and right self injective ring with 1 which contains a maximal annihilator right ideal.

2. LEMMA 2.1. *If I is a maximal annihilator right ideal of R then there exists an idempotent e in R such that $I=(e)^r$.*

Proof. Let I be a maximal annihilator right ideal of R. Then there exists $a\in R$ such that $I=(a)^r$. Let $L=\{r\in R\,|\,rI=0\}$ and let $S=L\wedge R_r^\Delta$. If $x\in S$ and $x^2\neq 0$ then $(x)^r=(x^2)^r$, since $(x)^r\leqq(x^2)^r$ and $(x)^r=I$. Let $y\in(x)^r\wedge xR$. Then $y=xr$ for some $r\in R$ and $xy=x(xr)=0=x^2r=xr=y$. This implies that $x\notin R_r^\Delta$. Thus if $x\in S$ then $x^2=0$. Hence, if $y\in S$ then $xy=0$ since $(x)^r=(y)^r$ or $y=0$. This implies that $S=(0)$ since R is semi-prime. Hence there exists a nonzero right ideal J in R such that $J\wedge I=(0)$. Let f be an R-homomorphism of $J\oplus I$ into R such that $f(j)=j$ for all $j\in J$ and $f(i)=0$ for all $i\in I$. Since R is right self injective, there must exist a nonzero element $e\in R$ such that $f(j)=ej=j$ for all $j\in J$ and $f(i)=ei=0$ for all $i\in I$. Since $(e^2-e)^r\geqq J\oplus I>I$ and I is a maximal annihilator right ideal, $e^2=e$. Since $ei=0$ for all $i\in I$, $I=(e)^r$.

LEMMA 2.2. *If I is a maximal annihilator right ideal of R then the module $R-I$ is isomorphic to eR for some idempotent e in R and $\mathrm{Hom}_R(eR, eR)$ is a division ring.*

Proof. By Lemma 2.1, $I=(e)^r$ for some idempotent $e\in R$. Since $x=(1-e)x$ for any $x\in(e)^r$, $(e)^r=(1-e)R$ and since $R=eR\oplus(1-e)R$, $R-I\cong eR$. Let $f\in\mathrm{Hom}_R(eR, eR)$ and $f\neq 0$. Since R is right self injective, there is $u\in R$ such that $f(er)=uer$ for all $er\in eR$. Define a relation g between ueR and eR by $g(uer)=er$ for all $uer\in ueR$. Then g is a mapping since $uer=uer'$ implies that $r-r'\in(ue)^r=(e)^r$. Clearly g is an R-homomorphism of ueR onto eR. Since eR is a direct summand of a right self injective ring R, eR must be injective as R-module. Hence there is an extension $\bar{g}$ of g to eR such that $\bar{g}\in\mathrm{Hom}_R(eR, eR)$ and $\bar{g}\cdot f$ is an identity mapping. Thus $\mathrm{Hom}_R(eR, eR)$ is a division ring.

THEOREM. *If R is a semi-prime and a right self injective ring with* 1, *then any maximal annihilator right ideal is a maximal right ideal which is generated by an idempotent in R.*

Proof. Let I be a maximal annihilator right ideal of R. Then, by Lemma 2.1, $I=(e)^r$ for some idempotent e in R. Hence $I=(1-e)R$. By [3; Proposition 3, p. 51] and by Lemma 2.2, $\mathrm{Hom}_R(eR, eR)=eRe$ is a division ring. Hence, by [3; Proposition 1, p. 65], eR must be a minimal right ideal of R. Thus $I=(e)^r$ is a maximal right ideal of R.

COROLLARY. *If R is a semi-prime and a right self injective ring with* 1 *which contains a maximal annihilator right ideal, then R contains a minimal right ideal and a minimal left ideal of R.*

REMARK. If we assume a maximum condition on annihilator right ideals in R, in addition, then by Lemma 2.1 $R_r^{\Delta}=0$. Since any complement right ideal of a right self injective ring is an annihilator right ideal (See [5] Lemma 2.4), a maximum condition on annihilator right ideals in R implies that a maximum condition on complement right ideals in R. Thus by a theorem of Goldie [2] and by [1; Th. 1], R is semi-simple Artinian.

LOCATION OF THE ZEROS OF A POLYNOMIAL

MOHAN LAL TIKOO, University of Jammu and Kashmir, India

That the zeros of the polynomial $P_n(z)=c_0+c_1z+\cdots+c_nz^n$, $c_n\neq 0$, are the eigenvalues of its companion matrix leads to easier methods in obtaining the bounds for all the zeros of a polynomial. Howard E. Bell [1], by making use of the Gershgorin's theorem [2], has obtained some well-known theorems as a direct consequence of the above fact. In this note we apply the Gershgorin's theorem to columns and obtain some simple bounds for the zeros of $P_n(z)$.

THEOREM (a). (Gershgorin). *Let $M\equiv[c_{ij}]$ be an (n, n) complex matrix, and let $C^{(i)}$ be the sum of the moduli of the off-diagonal elements in the i-th column. Then each eigenvalue of M lies in the union of the circles*

$$|z - c_{ii}| \leqq C^{(i)} \quad (i = 1, 2, 3, \cdots, n). \tag{1}$$

The analogous result holds if the rows of M are considered.

Like Bell, we take the larger circles $|z| \leqq |c_{ii}| + C^{(i)}$, $i = 1, 2, \cdots, n$.

THEOREM 1. *All the zeros of the polynomial $P_n(z) = c_0 + c_1 z + \cdots + c_n z^n$, $c_n \neq 0$, lie in the circle*

$$|z| \leqq \max\left(\frac{K_i}{K_{i+1}}, \sum_{i=0}^{n-1} \frac{|c_i|}{|c_n| K_{i+1}}\right) \quad (i = 0, 1, 2, \cdots, n-1) \tag{2}$$

where K_i are positive numbers with $K_0 = 0$ and $K_n = 1$.

Proof. The companion matrix $C(P_n)$ of the polynomial $P_n(z)$ is

$$C(P_n) = \begin{bmatrix} 0 & 0 & \cdots & 0 & -c_0/c_n \\ 1 & 0 & \cdots & 0 & -c_1/c_n \\ & & \cdots & & \\ 0 & 0 & \cdots & 1 & -c_{n-1}/c_n \end{bmatrix}.$$

Let $D = \operatorname{diag}(K_1, K_2, \cdots, K_n)$, where K_i are arbitrary positive numbers and $K_0 = 0$, $K_n = 1$, then

$$D^{-1}C(P_n)D = \begin{bmatrix} 0 & 0 & \cdots & 0 & -c_0/c_n K_1 \\ K_1/K_2 & 0 & \cdots & 0 & -c_1/c_n K_2 \\ & & \cdots & & \\ 0 & 0 & \cdots & K_{n-1}/K_n & -c_{n-1}/c_n K_n \end{bmatrix}$$

whence, by Theorem (a), the eigenvalues of $D^{-1}C(P_n)D$ lie in

$$|z| \leqq \max\left(\frac{K_i}{K_{i+1}}, \sum_{i=0}^{n-1} \frac{|c_i|}{|c_n| K_{i+1}}\right) \quad (i = 0, 1, 2, \cdots, n-1).$$

Since $D^{-1}C(P_n)D$ is similar to $C(P_n)$, the theorem follows.

COROLLARY 1. *All the zeros of $P_n(z)$ lie in the circle*

$$|z| \leqq \max\left(1, \sum_{i=0}^{n-1} |c_i| / |c_n|\right). \tag{3}$$

Proof. In (2) take $K_i = 1$ for all $i = 1, 2, \cdots, n$.

REMARK 1. The bound in (3) is best possible. If $P_n(z) = -nz^n + z^{n-1} + \cdots + z + 1$, then all the zeros of this polynomial lie in $|z| \leqq 1$. Obviously, $\sum_{i=0}^{n-1} |c_i|/|c_n| = 1$, and hence (3) gives the actual bound for the zeros of the considered polynomial.

REMARK 2. Inequality (3) also gives a traditional result that if $|c_0| + |c_1| + \cdots + |c_{n-1}| \leqq |c_n|$ then the zeros of $\sum_{i=0}^{n} c_i z^i$ lie in $|z| \leqq 1$.

COROLLARY 2. *Let* $P_n(z)=c_0+c_1z+c_2z^2+\cdots+c_nz^n$, *where* $c_i\neq 0$ *for all* $i=1, 2, \cdots, n$ *then all the zeros of* $P_n(z)$ *lie in*

$$|z| \leqq \max\left(|c_{i-1}|/|c_i|\, t, \sum_{i=1}^{n} 1/|c_n|\, t^i\right), \tag{4}$$

where $t>0$ *is arbitrary.*

Proof. In (2) put $K_i=|c_{i-1}|\, t^i$.

REMARK 3. The result obtained in (4) is best possible and can easily be verified if we take $P_n(z)=-nz^n+z^{n-1}+\cdots+z+1$, and $t=1$.

The referee has pointed out that the result of Corollary 1 is known. He has attributed this result to Parodi.

GENERALIZED BASES AND DIGITAL SUMS

J. R. TROLLOPE, University of Alberta

Many authors have considered problems dealing with digital sums of integers. For example, if we let $\alpha(n, r)$ denote the sum of the digits of n when n is represented in base r, then Legendre's theorem [1] states that

$$\alpha(n, r) = n + \sum_{i=1}^{\infty} (1-r)\left[\frac{n}{r^i}\right], \tag{1}$$

the square bracket denoting the integral part of its argument. Also, the asymptotic relation

$$A(n, r) \equiv \sum_{k<n} \alpha(k, r) = \frac{r-1}{2}\,\frac{n \log n}{\log r} + O(n), \tag{2}$$

has been discussed by various authors ([2]–[5]) and an explicit formula for $A(n, 10)$ has been given by d'Ocagne [6]. Lately there has been a renewed interest in generalized bases ([7], [8]) and the object of this paper is to consider digital sums relative to a particular type of generalized base.

Let $\{\xi_i | i=0, 1, 2, \cdots\}$ be a sequence of positive integers with $\xi_0=1$ and $\xi_i>1$ when $i\geqq 1$. Define the integers r_k by

$$r_k = \prod_{i\leq k} \xi_i. \tag{3}$$

It can be easily shown that every positive integer n has a unique representation of the form

now show that $p|C: C \to p(C)$ is injective. Let $x, y \in C$ be such that $p(x) = p(y) = b$. Since C is pathwise connected there exists a path $\beta: I \to C$ such that $\beta(0) = x$ and $\beta(1) = y$. Thus, $\alpha = p \circ \beta$ is a closed path in U with initial point b. Thus there exists a contracting homotopy of α in B. Since (X, p, B) has the contractible lifting property, there exists a contracting homotopy F of α in B which has a lifting F' such that $F'(t, 0) = \beta(t)$. Define $f: I \to X$ by $f(s) = F'(0, s)$. Since $p \circ f(s) = p \circ F'(0, s) = b$, f is a path in $p^{-1}(b)$ and since $p^{-1}(b)$ is totally pathwise disconnected, f is constant. Since $f(0) = F'(0, 0) = \beta(0) = x$, $f(s) = x$ for all $s \in I$. Thus, in particular $F'(0, 1) = x$. Define $g: I \to X$ by $g(s) = F'(1, s)$. A similar argument shows that g is constant and since $g(0) = F'(1, 0) = \beta(1) = y$, $g(s) = y$ for all $s \in I$. Thus, in particular, $F'(1, 1) = y$. Define $h: I \to X$ by $h(t) = F'(t, 1)$. The same argument shows that h is constant. But $h(0) = F'(0, 1) = x$ and $h(1) = F'(1, 1) = y$. Hence $x = y$. It follows that $p|C$ is injective and hence is a homeomorphism. Hence (X, p, B) is a sheaf.

Easy examples show that the triple (X, p, B) of the above theorem is in general not a covering space. Thus, under the hypotheses of the above theorem and the theorem of Browder, we have completed the diagram below

$$\begin{array}{ccc} \text{WEAK FIBRE SPACE} & \Rightarrow & \text{SEMI-WEAK FIBRE SPACE} \\ \Downarrow & & \Downarrow \\ \text{COVERING SPACE} & \Rightarrow & \text{SHEAF.} \end{array}$$

NOTE ON THE SINGLE VARIABLE BELL POLYNOMIALS

JOHN BRILLHART, University of California, Berkeley

In a recent paper [1, p. 22] L. Carlitz has shown that the single variable Bell polynomials $A_n(x)$ have no repeated roots by relating them to the cyclotomic polynomials mod 2. In this note we establish this result by two other mod 2 arguments.

The polynomials $A_n(x)$ can be defined by

$$A_n(x) = \sum_{k=0}^{n} S(n, k)x^k, \; n \geqq 0, \quad \text{where} \quad S(n, k) = \frac{1}{k!}\sum_{r=0}^{k} (-1)^{k-r}\binom{k}{r} r^n$$

are the Stirling numbers of the second kind. The first few of these polynomials are:

$$A_0(x) = 1, \quad A_1(x) = x, \quad A_2(x) = x^2 + x,$$
$$A_3(x) = x^3 + 3x^2 + x, \quad A_4(x) = x^4 + 6x^3 + 7x^2 + x.$$

The $A_n(x)$ are most easily generated by the recursion formula

$$A_{n+1}(x) = x[A_n(x) + A_n'(x)], \qquad n \geqq 0. \tag{1}$$

For simplicity we write $A_n = A_n(x)$.

THEOREM. *A_n has no multiple roots.*

Proof 1. According to a result of Touchard [2], we have $A_{n+p} \equiv A_{n+1} + x^p A_n \pmod{p}$ for p a prime, $n \geqq 0$. Putting $p = 2$ and shifting the index, we can write

$$A_n \equiv A_{n+1} + x^2 A_{n-1} \pmod 2, \qquad n \geqq 1. \tag{2}$$

If (2) is combined with (1), we obtain

$$(x + 1)A_n + xA_n' \equiv x^2 A_{n-1} \pmod 2. \tag{3}$$

Now let $d(x)$ be the G.C.D. of A_n and A_n'. Then $d(x)$ will be monic with integral coefficients, since A_n has these properties. From (3) we see that $d(x) \pmod 2$ will divide $x^2 A_{n-1}$, inasmuch as it divides the left side of the identity. But the constant term of A_n' is 1, so that $x \nmid d(x) \pmod 2$. Hence, $d(x) \mid A_{n-1} \pmod 2$. It now follows from repeated use of (2) that $d(x)$ will in turn divide A_{n-2}, A_{n-3}, $\cdots$, $A_0 = 1 \pmod 2$. Thus, $d(x) \equiv 1 \pmod 2$. But $d(x)$ is monic. Therefore, $d(x) = 1$, which proves the theorem.

Proof 2: Put $A_n = xB_n$. Then B_n satisfies the comparable modular identities $B_n \equiv B_{n-1} + x^2 B_{n-2} \pmod 2$ and $B_n' \equiv B_n + xB_{n-1} \pmod 2$. We now show that the discriminant D of B_n is odd, and hence not 0. For our purposes then, it will suffice to compute $D(B_n) \pmod 2$. We do this by appealing to both the well-known relations between $D(B_n)$ and the resultant $R(B_n, B_n')$ and the properties of R. (See Uspensky [3], Swan [4, 1104].) Thus,

$$\begin{aligned} D(B_n) &\equiv R(B_n, B_n') \equiv R(B_n, B_n + xB_{n-1}) = R(B_n, xB_{n-1}) \\ &= R(B_n, x)R(B_n, B_{n-1}) = R(B_n, B_{n-1}) = R(B_{n-1}, B_n) \\ &\equiv R(B_{n-1}, B_{n-1} + x^2 B_{n-2}) = R(B_{n-1}, x^2 B_{n-2}) \\ &= R(B_{n-1}, B_{n-2}) = \cdots = R(B_2, B_1) = 1 \pmod 2. \end{aligned}$$

In general, if F and G are two polynomials, then $D(FG) = D(F)D(G)\,[R(F,G)]^2$. Hence, $D(A_n) = D(xB_n) = D(B_n) \equiv 1 \pmod 2$.

REMARK: It is clear from the above proofs that A_n also has no multiple factors mod 2.

MEDIANS OF A SIMPLEX

ARUN SANYAL, Indian Institute of Technology, Kharagpur, India

The purpose of this note is to establish a theorem on medians of a simplex in n-dimensional Euclidean space $E[n]$.

Let $A_0A_1 \cdots A_n$ be a simplex $\mathcal{S}$ in $E[n]$. Any r vertices of the simplex form an $(r-1)$-simplex and the rest of the vertices form an $(n-r)$-simplex. These two opposite simplexes will be denoted respectively by $\mathcal{S}_{r-1}$ and $\mathcal{S}_{n-r}$. There are $\binom{n+1}{r}$ pairs of opposite simplexes. We shall take $r \leqq n+1-r$.

The line joining the centroids of two opposite $\mathcal{S}_{r-1}$ and $\mathcal{S}_{n-r}$ will be called (cf. [2]) an r-median of $\mathcal{S}$. If $r=n+1-r$, an r-median will be called a bimedian. There are then $\frac{1}{2}\binom{2r}{r}$ bimedians of an $\mathcal{S}$ in $E[2r-1]$. A 1-median will be called a median.

In the following theorem, we shall denote by A_i the coordinate vector of a point A_i with respect to an origin, and the scalar product $A_i \cdot A_i$ by A_i^2.

THEOREM. *The sum of the squares of* $\binom{n+1}{r}$ *r-medians of a simplex* $\mathcal{S}$ *in* $E[n]$ is $[(n+1)!]/[nr(n-r+1)(n-r+1)!r!]$ *times the sum of the squares of its edges if* $r \neq n+1-r$.

Proof. Let d be the sum of the squares of the edges. Then

$$d = \sum_{i<j} (A_i - A_j)^2 \qquad (i, j = 0, 1, \cdots, n).$$

Since n edges pass through each vertex,

$$d = n \sum_{i=0}^{n} A_i^2 - 2 \sum_{i<j} A_i \cdot A_j.$$

Let us denote the sum of the squares of the r-median by D. The square of the length of one r-median is

$$\left(\frac{A_0 + A_1 + \cdots + A_{r-1}}{r} - \frac{A_r + A_{r+1} + \cdots + A_n}{n-r+1} \right)^2.$$

Now, (a) there are

$$\binom{n}{r-1} \mathcal{S}_{r-1} \quad \text{and} \quad \binom{n}{n-r} \mathcal{S}_{n-r}$$

which have the vertex A_i. So the coefficient of A_i^2 in D is

$$\frac{1}{r^2}\binom{n}{r-1} + \frac{1}{(n-r+1)^2}\binom{n}{n-r} = \frac{(n+1)!}{r(n-r+1)(n-r+1)!r!}$$

and, (b) there are

$$\left[\binom{n-1}{r-2}\right] \mathcal{S}_{r-1} \quad \text{and} \quad \left[\binom{n-1}{n-r-1}\right] \mathcal{S}_{n-r}$$

which have both the vertices A_i, A_j. Also, there are

$$\left[\binom{n}{r-1}-\binom{n-1}{r-2}\right]\mathfrak{S}_{r-1} \quad \text{and} \quad \left[\binom{n-1}{r-2}-\binom{n-1}{n-r-1}\right]\mathfrak{S}_{n-r}$$

which have the vertex A_i or A_j. So the coefficient of $A_i \cdot A_j$ in D is given by the following expression:

$$2\left[\frac{(n-1)!}{r^2(r-2)!(n-r+1)!}+\frac{(n-1)!}{(n-r+1)^2 r!(n-r-1)!}\right.$$
$$\left.-\frac{2(n-1)!}{r(n-r+1)(n-r)!r!}\right]=\frac{-2(n+1)!}{nr(n-r-1)(n-r+1)!r!}.$$

Hence

$$D=\frac{(n+1)!}{nr(n-r+1)(n-r+1)!r!}\left[n\sum_{i=0}^{n}A_i^2-2\sum_{i<j}A_i\cdot A_j\right]$$
$$=\frac{(n+1)!}{nr(n-r+1)(n-r+1)!r!}d.$$

Putting $r=1$, in the result of the theorem, we get

$$D=\frac{n+1}{n^2}d,$$

which can be written in the following way: The sum of the squares of the medians of a simplex is $(n+1)/n^2$ times the sum of the squares of the edges. The result for $n=2$ can be found in books of school geometry, (cf. [3] pp. 231, Ex 9) and for $n=3$ we get it in [1, p. 65].

If $n=2r-1$ there are

$$\frac{1}{2}\binom{2r}{r}$$

bimedians and

$$D=\frac{(2r)!}{2r^2(2r-1)r!r!}d.$$

For $n=3$ this reduces to the result given in [1, p. 64] and [4, p. 67].

Thanks are due to Dr. Sahib Ram Mandan for his guidance in preparation of this note.

THE INVOLUTORY ANTIAUTOMORPHISMS OF THE QUATERNION ALGEBRA

RABE VON RANDOW, Otago University, Dunedin, New Zealand

Let H denote the algebra of quaternions and A^* the set of automorphisms and antiautomorphisms of H. Clearly A^* is a group and, since the square of any antiautomorphism is an automorphism, the automorphisms of H form a subgroup A of index 2 in A^*. Furthermore, as H is a vector space of dimension 4 over the field R of real numbers, A and A^* are clearly subgroups of $GL(4, R)$. The object of this note is to determine the involutory antiautomorphisms of H. If E is an involutory antiautomorphism of H and $P \in A^*$, then obviously $P^{-1}EP$ is again an involutory antiautomorphism of H, and we will say that E and $P^{-1}EP$ are equivalent modulo A^*. We will show that, up to equivalence mod A^*, there are only two involutory antiautomorphisms of H, namely

$$\begin{aligned} &a + bi + cj + dk \to a - bi - cj - dk, \\ &a + bi + cj + dk \to a - bi + cj + dk. \end{aligned} \tag{1}$$

The first of these is of course the usual conjugation of quaternions. In [1] we consider Hermitian forms over H, utilising the second involutory antiautomorphism. This gives rise to a theory of Hermitian forms completely analogous to that of quadratic forms over C, whereas the usual theory of Hermitian forms over H is analogous to that of quadratic forms over R or Hermitian forms over C.

Determination of A and A^*. Suppose that $S \in A^*$, $S \notin A$, and express S as a real 4×4 matrix with respect to the usual base of H. Then, as

$$\begin{aligned} &S(1) = 1, \qquad (S(i))^2 = (S(j))^2 = (S(k))^2 = -1, \\ &S(j)\cdot S(i) = S(k), \quad S(k)\cdot S(j) = S(i), \quad S(i)\cdot S(k) = S(j), \end{aligned} \tag{2}$$

an easy calculation shows that S is of the form

$$S = \begin{pmatrix} 1 & 0 \\ 0 & T \end{pmatrix},$$

where T is orthogonal of determinant -1.

Similarly, suppose that $S \in A$. Then the relations (2) and $S(i)\cdot S(j) = S(k)$, $S(j)\cdot S(k) = S(i)$, $S(k)\cdot S(i) = S(j)$ show that S is of the form

$$S = \begin{pmatrix} 1 & 0 \\ 0 & T \end{pmatrix},$$

where T is orthogonal of determinant 1.

Determination of the involutory antiautomorphisms of H. Let E be an involutory antiautomorphism of H. Then E has the form

$$E = \begin{pmatrix} 1 & 0 \\ 0 & F \end{pmatrix},$$

where F is orthogonal of determinant -1 and involutory, hence symmetric and orthogonal of determinant -1. The eigenvalues of E can therefore only be 1, 1, 1, -1, and 1, -1, -1, -1. Hence E has, with respect to some base in H, one of the following standard forms:

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}.$$

The first three are equivalent mod A^*, however, and not equivalent to the last one, as they have differing eigenvalues. This leaves the two involutory anti-automorphisms (1), which are clearly the only ones mod A^*, as equivalence mod A^* is nothing but equivalence under orthogonal reduction.

The involutory automorphisms of H are obtained similarly.

IF $R[X]$ IS NOETHERIAN, R CONTAINS AN IDENTITY

R. W. GILMER, JR., Florida State University

The well-known Hilbert basis theorem shows that if R is a commutative ring with identity and if R is Noetherian, then $R[X]$, the polynomial ring in one indeterminate over R, is also Noetherian. In this note we establish the converse of this result.

THEOREM. *If R is a commutative ring such that $R[X]$ is Noetherian, then R contains an identity.*

Proof. The mapping $f(X) \to f(0)$ is a homomorphism of $R[X]$ onto R. Hence R is Noetherian. If now $r \in R$, then the chain of ideals $(r) \subseteq (r, rX) \subseteq \cdots \subseteq (r, rX, \cdots, rX^n) \subseteq \cdots$ contains only finitely many distinct ideals. Thus, for some n, $rX^{n+1} \in (r, rX, \cdots, rX^n)$, say

$$(*) \qquad rX^{n+1} = \sum_{i=0}^{n} f_i(X) \cdot rX^i + \sum_{i=0}^{n} n_i \cdot rX^i,$$

where $f_i(X) = \sum_{j=0}^{m_i} f_j^{(i)} X^j$, $f_j^{(i)} \in R$, and each n_i is an integer. Equating coefficients of X^{n+1} in (*) we have $r = \sum_{i=0}^{n} (f_{n-i}^{(i)} \cdot r) = g \cdot r$ where $g = \sum_{i=0}^{n} f_{n-i}^{(i)} \in R$. We then note that for any elements $r_1, r_2, g_1, g_2 \in R$ such that $r_1 = g_1 r_1$ and $r_2 = g_2 r_2$, we have $r_1 = (g_1 + g_2 - g_1 g_2) r_1$ and $r_2 = (g_1 + g_2 - g_1 g_2) s$. By induction it follows that if $\{r_i\}_{i=1}^{k}$ is a finite set of elements of R then there exists an element $u \in R$ such that $r_i = ur_i$ for $i = 1, \cdots, k$. Since R is Noetherian, there is a finite subset T of R such that T generates R as an ideal of R. If $e \in R$ is such that $et = t$ for each $t \in T$, then it follows that e is an identity of R.

RELATING PROPER AND NORMAL CONES

M. D. LEVIN, University of Iowa

In [1], Namioka states that in pseudo-normed spaces, normal cones are proper. The statement is true only in normed spaces. Moreover, in normed euclidean spaces cones are normal if and only if their closures are proper. An example is given to demonstrate that this fact is not necessarily true in other normed spaces.

Notation. The closed unit ball in a pseudo-normed space will be denoted S.

DEFINITIONS. *Let E be a real linear space.* (1) *A subset C of E is a cone in E if, whenever x, $y\in C$ and $t\geqq 0$, both tx and $x+y\in C$.* (2) *A cone C in E is proper in case $x\in C$ and $-x\in C$ imply $x=0$.* (3) *If p is a pseudo-norm on E, a cone C in E is normal if $(S+C)\cap(S-C)$ is p-bounded.* (4) *If x is a nonzero element of E, $Rx=\{tx: t\in R\}$ is called a line.*

Notes. (1) If C is a cone in a topological vector space, then $\overline{C}$ is a cone. (2) A cone is proper if and only if it contains no line.

PROPOSITION 1. *If C is a normal cone in a normed space, then C is proper.*

Proof. If C is not proper, then there is a line L in C. Then $L\subset(S+C)\cap(S-C)$. Hence, $(S+C)\cap(S-C)$ is not bounded.

Example. A normal cone in a pseudo-normed space need not be proper. Let p be the pseudo-norm on R^2 given by $p((x, y))=|x|$. Then $S=\{(x, y): |x|\leqq 1\}$. Let $C=\{(x, y): x\geqq 0\}$. $(S+C)\cap(S-C)=S$, so C is normal. But $(0, 1)$ and $-(0, 1)$ belong to C, so C is not proper.

PROPOSITION 2. *Let C be a normal cone in a pseudo-normed space. Then $\overline{C}$ is normal.*

Proof. $\overline{C}\subset C+S=C-S$. Hence, $S+\overline{C}\subset 2S+C=2(S+C)$ and $S-\overline{C}\subset 2(S-C)$. It follows that

$$(S+\overline{C})\cap(S-\overline{C})\subset 2[(S+C)\cap(S-C)].$$

Since $(S+C)\cap(S-C)$ is bounded, so is $(S+\overline{C})\cap(S-\overline{C})$.

PROPOSITION 3. *Let p be a norm on R^n. Let C be a closed proper cone in R^n. Then C is normal.*

Proof. Suppose that $(S+C)\cap(S-C)$ is not p-bounded. Then there exists a sequence $\{x_j\}$ in $(S+C)\cap(S-C)$ such that $p(x_j)\to\infty$. Since S is compact, one can assume that $x_j/p(x_j)\to y$. Because $p(y)=1$, $y\neq 0$. Write $x_j=u_j+v_j$, where $u_j\in S$ and $v_j\in C$. Then $v_j/p(x_j)=x_j/p(x_j)-u_j/p(x_j)$. The right hand member of this equation converges to y. Since $v_j/p(x_j)\in C$ and C is closed, $y\in C$. Similarly $-y\in C$. Then C is not proper.

PROPOSITION 4. *Let p be a norm on R^n. Let C be a cone in R^n. Then C is normal if and only if $\overline{C}$ is proper.*

Proof. If $\overline{C}$ is proper then, by proposition 3, $(S+\overline{C})\cap(S-\overline{C})$ is p-bounded. But $(S+C)\cap(S-C)\subset(S+\overline{C})\cap(S-\overline{C})$. Then C is normal. On the other hand, if C is normal, then by proposition 2, $\overline{C}$ is normal, and by proposition 1, $\overline{C}$ is proper.

THEOREM. *A cone C in a pseudo-normed linear space (E, p) is normal if and only if there exists $e>0$ such that whenever $x, y\in C$ and $p(x)=p(y)=1$, it is true that $p(x+y)\geqq e$.*

Proof. Namioka [1], page 30.

Example. A closed proper cone in a non-euclidean normed space need not be normal. Let $\|\ \|$ be the usual norm on R^2. Let E be the set of all sequences $\{x_n\}$ with values in R^2 such that $\sum_{n=1}^{\infty}\|x_n\|^2$ is a convergent series. Define norm p on E by $p(\{x_n\})=(\sum_{n=1}^{\infty}\|x_n\|^2)^{1/2}$. E is actually a Hilbert space. Let $C_n=\{(y, z)\in R^2: yn^2-|z|\geqq 0\}$. Then C_n is $\|\ \|$-closed in R^2. Let $C=\{\{x_n\}\in E: x_n\in C_n$ for each $n\}$. Then C is a closed complete proper cone in (E, p) but C is not normal.

Proof. Suppose that C is normal. Then, by the theorem, there exists $e>0$ such that if $u, v\in C$ and $p(u)=p(v)=1$, then $p(u+v)\geqq e$. Let N be an integer such that $N>2/e$. Let δ_{ij} be the Kronecker delta. Let $u=\{u_n\}$ be the element of E such that $u_n=\delta_{nN}\,(1/N,\ (N^2-1)^{1/2}/N)$. Let $v=\{v_n\}$ be the element of E such that $v_n=\delta_{nN}(1/N,\ -(N^2-1)^{1/2}/N)$. $u, v\in C$; $p(u)=p(v)=1$; $p(u+v)=2/N<e$. Contradiction.

The author thanks the referee for suggesting simplifications in most of the original proofs.

COMPACT CONVEX SETS IN INNER PRODUCT SPACES

S. K. BERBERIAN, University of Iowa

G. H. Orland recently proved that a compact convex set of complex numbers is generated by its bare points [3, p. 78, Lemma 3]. In this note we show that Orland's arguments extend to any inner product space; the Krein-Milman theorem for inner product spaces follows as a corollary.

For the rest of the paper E denotes a nonzero inner product space, with inner product (x, y); for definiteness we assume that E is a complex inner product space, though the arguments are also valid for real inner product spaces, with the simplification $\Re(x, y)=(x, y)$ ($\Re$ denotes real part). Our convention is that convex sets are nonempty.

DEFINITION. *Let C be a convex subset of the inner product space E. A point x of C will be called a bare point of C if there exists a point x_0 in E and a real number $r>0$ such that $\|x-x_0\|=r$ and $\|y-x_0\|\leqq r$ for all y in C; informally, there exists a closed ball containing C, with x on the surface (i.e., there exists a sphere through x which encloses C).*

It is a well-known property of inner product spaces that every point of the sphere $\|x-x_0\|=r$ is an extremal point of the closed ball $\|x-x_0\| \leqq r$ (see [1] p. 32, Exercises 4 and 5); it follows at once that every bare point of a convex set C in E is an extremal point of C.

THEOREM. *A compact convex set in an inner product space is the closed convex hull of its bare points.*

Before giving the proof, which follows Orland's model faithfully, we note an immediate corollary: a compact convex set in an inner product space is the closed convex hull of its extremal points; this is the Krein-Milman theorem for inner product spaces (cf. [2] p. 84). This result carries over at once to any topological vector space which is normable by an inner product—for instance, any finite-dimensional separated topological vector space [2, p. 27, Théorème 2].

The following lemmas are "geometrically obvious" and surely well known; we suppress most of the details.

LEMMA 1. *Let A be a convex set in E, and let x_0 be a point of E not in A. Suppose that there exists a point y_0 in A such that*

$$\|x_0 - y_0\| \leqq \|x_0 - y\| \qquad \text{for all } y \text{ in } A.$$

Then $\Re(x_0-y_0, y) \leqq \Re(x_0-y_0, y_0)$ for all y in A.

Proof. Consider first the case that $y_0=0$, and fix a point y in A. For any α with $0<\alpha<1$ we have $\alpha y \in A$, and so $\|x_0\|^2 \leqq \|x_0-\alpha y\|^2$; thus $2\Re(x_0, y) \leqq \alpha\|y\|^2$, and $\Re(x_0, y) \leqq 0$ results on letting α tend to zero. The general case follows at once by translation.

LEMMA 2. *With notations as in Lemma 1, assume moreover that A is bounded. Then there exists a positive integer n such that A is contained in the closed ball with center $w_0 = -n(x_0-y_0)+y_0$ and radius $r_0=(n+1)\|x_0-y_0\|$.*

Proof. By translation one may assume that $y_0=0$. Suppose, on the contrary, that for each n there exists a point y_n in A such that

$$\|y_n - (-nx_0)\| > (n+1)\|x_0\|;$$

by squaring both sides and invoking Lemma 1, one arrives at

$$\|x_0\|^2 < \|y_n\|^2(1+2n)^{-1},$$

and since $\|y_n\|$ is bounded this implies $x_0=0$, a contradiction (recall that $x_0 \notin A$). With notation as in the statement of Lemma 2, we remark that x_0 lies on the surface of the indicated closed ball, that is, $\|x_0-w_0\|=r_0$.

LEMMA 3. *With notations as in Lemma 1, let $u_0=(x_0+y_0)/2$. Then $\|u_0-y_0\| \leqq \|u_0-y\|$ for all y in A.*

Proof. For all y in A,

$$\|x_0 - y\| \geqq \|x_0 - y_0\| = \|x_0 - u_0\| + \|u_0 - y_0\|,$$

whence

$$\|u_0 - y_0\| \leqq \|x_0 - y\| - \|x_0 - u_0\|;$$

the lemma then follows at once from the inequality

$$|\,\|x_0 - y\| - \|x_0 - u_0\|\,| \leqq \|u_0 - y\|.$$

Proof of the theorem. Assume that C is a compact convex subset of the inner product space E; in particular, C is complete and bounded. Let S be the set of all bare points of C; one argues exactly as in [3] that S is nonempty (an endpoint of a segment in C of maximal length is a bare point). Let D be the closed convex hull of S; thus $D \subset C$, and D is compact and convex. It is to be shown that $D = C$.

Assume, on the contrary, that there is a point z_0 of C which does not belong to D. Let y_0 be the unique point of D such that

$$\|z_0 - y_0\| \leqq \|z_0 - y\| \qquad \text{for all } y \text{ in } D$$

(cf. [1] p. 68, Theorem 1); setting $x_0 = (z_0 + y_0)/2$, we have

$$\|x_0 - y_0\| \leqq \|x_0 - y\| \qquad \text{for all } y \text{ in } D$$

by Lemma 3. Observe that $x_0 \notin D$, since

$$\|z_0 - x_0\| = \tfrac{1}{2}\|z_0 - y_0\| < \|z_0 - y_0\|.$$

By Lemma 2 there exists a positive integer n such that D is contained in the closed ball with center $w_0 = -n(x_0 - y_0) + y_0$ and radius $r_0 = (n+1)\|x_0 - y_0\|$. Thus

$$\|y - w_0\| \leqq r_0 \qquad \text{for all } y \text{ in } D, \tag{1}$$

and, as noted earlier,

$$\|x_0 - w_0\| = r_0. \tag{2}$$

On the other hand the point z_0 does not belong to this closed ball, since by (2)

$$\|z_0 - w_0\| = \|z_0 - x_0\| + \|x_0 - w_0\| > \|x_0 - w_0\| = r_0;$$

thus

$$\|z_0 - w_0\| > r_0. \tag{3}$$

Let $r = \sup\{\|x - w_0\| : x \in C\}$; since $z_0 \in C$ we have

$$r \geqq \|z_0 - w_0\| > r_0 \tag{4}$$

by (3). By compactness there is a point u of C such that $\|u - w_0\| = r$; since

$$\|x - w_0\| \leqq r \qquad \text{for all } x \text{ in } C,$$

by the definition of r, it follows that u is a bare point of C. Then $u \in S \subset D$ and therefore $\|u - w_0\| \leqq r_0$ by (1); that is, $r \leqq r_0$, contrary to (4).

NONPERIODICITY OF SOLUTIONS OF A THIRD ORDER EQUATION

W. R. Utz, University of Missouri

In Problem 5195, (this Monthly, 72 (1965) p. 433), A. C. Lazer shows that for the differential equation

$$y''' - p(x)y = 0, \tag{1}$$

wherein $p(x)$ is positive and continuous in an interval I, no solution can be tangent to the line $y=0$ more than once in I. That solutions of (1) may have one tangency is clear from the fact that initial conditions

$$y(a) = y'(a) = 0, \qquad y''(a) \neq 0$$

may be assumed.

Suppose that $p(x)$ is positive and continuous for all real x, then if $y''(a)$ is selected to be positive, it is known (M.Švec, Czechoslovak Math. J., (7) 82 (1957) pp. 450–462) that for this solution

$$\lim_{x\to\infty} y(x) = \lim_{x\to\infty} y'(x) = \infty \quad \text{and} \quad \lim_{x\to\infty} y''(x)$$

exists but may be infinite. In case, for this one solution, $\lim_{x\to\infty} y''(x) < \infty$, no solution of the equation oscillates (i.e., has positive maxima and negative minima for arbitrarily large x).

Since $-y(x)$ satisfies (1) if $y(x)$ does, a similar result is available at once if $y''(a) < 0$.

The purpose of this note is to point out that by using the same argument the theorem of Lazer is valid for

$$y''' - p(x)f(y) = 0, \tag{2}$$

where $f(y)$ is an odd function, and, moreover, solutions are not periodic.

Theorem 1. *If $p(x)$ is continuous and positive in the interval I: $[a, b]$ and if for all real y,*

$$yf(y) > 0 \qquad \textit{for } y \neq 0,$$

then no solution $y \not\equiv 0$ of (2) in (a, b) can be tangent to $y=0$ more than once.

Proof. Let $y(x) \not\equiv 0$ be a solution of (2), valid in (a, b) and consider

$$v(x) = y''y - \tfrac{1}{2}y'^2. \tag{3}$$

Since $v'(x)=y'''(x)y(x)=p(x)y(x)f(y(x))>0$ for $y\neq 0$, $v(x)$ is a continuous strictly increasing function. Hence $v(x)$ has at most one zero. Since $y(x)=y'(x)=0$ implies that $v(x)=0$, the theorem is proved.

THEOREM 2. *Under the hypotheses of the previous theorem, no solution of* (2) *is periodic.*

Proof. If $y(x)$ is a periodic solution of (2) of period $t>0$, then

$$v(x) = y''(x)y(x) - (y'(x))^2/2$$

is continuous and periodic of period t. As in the proof of Theorem 1, however,

$$v'(x) > 0$$

for $y(x)\neq 0$; hence $v(x)$ never decreases and can't be periodic.

NOTE ON ABSTRACT COMMUTATIVE IDEAL THEORY

P. J. MCCARTHY, University of Kansas

Let L be a multiplicative lattice that is commutative and residuated. We denote the join and meet of two elements a, $b\in L$ by $a\cup b$ and $a\cap b$, respectively. There is a multiplication defined on L such that $ab\leqq a\cap b$, $ab=ba$, and $a(b\cup c)=ab\cup ac$ for all a, b, $c\in L$. Further, for each pair of elements a, $b\in L$ there is an element $a:b\in L$ characterized by the fact that if $c\in L$ then $bc\leqq a$ if and only if $c\leqq a:b$. The element $a:b$ is called the *residual* of a by b. Various properties of the operations of join, meet, multiplication, and residuation are given in [3] and in [1, pp. 482–483].

An element $m\in L$ is called *join principal* if $(a\cup bm):m=a:m\cup b$ for all a, $b\in L$, *meet principal* if $(a\cap b:m)m=am\cap b$ for all a, $b\in L$, and *principal* if it is both join principal and meet principal. This definition of principal element is that given by Dilworth [1]: it is, in general, different from the definition of principal element used by Ward and Dilworth in [3]. On page 497 of [1], Dilworth points out that every element of the lattice $L(R)$ of ideals of a ring R is principal when R is a Dedekind domain. This prompts the following question: for which rings R (commutative and with unity) is every element of $L(R)$ principal? We emphasize that the principal elements of $L(R)$ are not the same as the principal ideals of R. Every principal ideal of R is a principal element of $L(R)$ [1, p. 481], but there may be principal elements of $L(R)$ which are not principal ideals of R, as the remark about Dedekind domains shows. In this note we shall answer the question we have asked, at least for Noetherian rings.

We shall call the lattice L an *M-lattice* if it satisfies the following condition: if a, $b\in L$ and if $a\leqq b$ then there is an element $c\in L$ such that $a=bc$.

THEOREM 1. *Let L be a commutative and residuated multiplicative lattice satisfying* (1) *the ascending chain condition, and* (2) *every element of L is a join of principal elements. Then, every element of L is principal if and only if L is an M-lattice.*

Proof. Suppose that L is an M-lattice. Then, by [3, Theorem 13.2], L is a distributive lattice. (We caution the reader that the use of the word principal in Theorem 13.2 of [3] is not the same as in this note.) It is a consequence of (1) and (2) that every element of L is a join of a finite number of principal elements. Therefore, to show that every element of L is principal, it is sufficient to show that the join of two join principal elements is join principal and that the join of two meet principal elements is meet principal.

Let m be a join principal element of L and suppose $m \leqq d$ for some $d \in L$. Then $m = cd$ for some $c \in L$, and since m is join principal, $(a \cup bcd) : cd = a : m \cup b$ for all $a, b \in L$. Hence $((a \cup bcd) : c) : d = a : m \cup b$. However, $(a \cup bd)c = ac \cup bcd \leqq a \cup bcd$, and consequently $a \cup bd \leqq (a \cup bcd) : c$. Therefore, $(a \cup bd) : d \leqq a : m \cup b$ for all $a, b \in L$. Thus, if m and n are join principal elements of L, we have for all $a, b \in L$,

$$\begin{aligned}(a \cup b(m \cup n)) : (m \cup n) &\leqq (a : m \cup b) \cap (a : n \cup b) \\ &= (a : m \cap a : n) \cup b = a : (m \cup n) \cup b.\end{aligned}$$

Since the reverse inequality always holds, $m \cup n$ is join principal.

Now, let m be a meet principal element of L and suppose that $m \leqq d$ for some $d \in L$. Then $m = cd$ for some $c \in L$, and since m is meet principal, $(a \cap b : cd)cd = am \cap b$ for all $a, b \in L$. Then, since $(b : cd)c = ((b : d) : c)c \leqq b : d$, we have $am \cap b \leqq (ac \cap (b : cd)c)d \leqq (a \cap b : d)d$ for all $a, b \in L$. Thus, if m and n are meet principal elements of L then we have, for all $a, b \in L$,

$$\begin{aligned}(a \cap b : (m \cup n))(m \cup n) &\geqq (am \cap b) \cup (an \cap b) \\ &= (am \cup an) \cap b = a(m \cup n) \cap b.\end{aligned}$$

Since the reverse inequality always holds, $m \cup n$ is meet principal.

If every element of the lattice L is meet principal (and so, if every element of L is principal) then for every $a, b \in L$ we have $a \cap b = (a : b)b$ [1, Corollary 3.1]. Hence, if $a \leqq b$ then $a = bc$ where $c = a : b$. Therefore, L is an M-lattice. This completes the proof of Theorem 1. Note that we have shown that if every element of L is meet principal then every element of L is join principal, and so principal.

A commutative ring R with unity is called a *multiplication ring* if $L(R)$ is an M-lattice. These rings have been the object of considerable study (for example, see [2] and the references in that paper). From Theorem 1 we obtain the following result, which answers the question asked earlier, at least for Noetherian rings.

THEOREM 2. *Let R be a Noetherian commutative ring with unity. Then every element of $L(R)$ is principal if and only if R is a multiplication ring.*

CLASSROOM NOTES

Material for this department should be sent to George Raney, Department of Mathematics, University of Connecticut, Storrs, CT 06268.

THE FIRST SYMMETRIC DERIVATIVE

C. E. AULL, Virginia Polytechnic Institute

1. Introduction. This note is concerned with the symmetric derivative

$$f^s(x) = \lim_{h \to 0} \frac{f(x+h) - f(x-h)}{2h}$$

and its relation with the ordinary derivative and the Lipschitz condition for a function of one variable. The symmetric derivative has applications to Fourier series and the Poisson integral. For a discussion of these, see A. Zygmund, [5, p. 100]. Throughout the paper "$G(x)$ exists" will mean "$G(x)$ exists and is finite."

It may happen that $f^s(a)$ exists even when $f(a)$ does not. The function $f(x) = 1/x^2$ has a symmetric derivative even at 0, $f^s(0)$ being 0.

The Dirichlet function [$f(x) = 1$ for x rational and $f(x) = 0$ for x irrational] has a symmetric derivative for rational points but not for irrational points.

2. Relation to the ordinary derivative. It is well known [5, p. 22] that if the ordinary derivative exists at a point, then the symmetric derivative does also. This result follows from the limit of the sum theorem and the following expression

$$\frac{f(x+h) - f(x-h)}{2h} = \frac{f(x+h) - f(x)}{2h} + \frac{f(x) - f(x-h)}{2h}.$$

But even the continuity of $f(x)$ and the existence of $f^s(x)$ does not guarantee the existence of $f'(x)$; for example, consider $f(x) = |x|$ at 0.

It will be shown here by means of a sequence of theorems that the continuity of $f^s(x)$ at a point "a" and the continuity of $f(x)$ in a neighborhood of "a" suffice for the existence of $f'(a)$.

LEMMA 1. *Let $f(x)$ be continuous on $a \leqq x \leqq b$ and let $f^s(x)$ exist on $a < x < b$. Let $f(b) > (<) f(a)$. Then there exists a point c, $a < c < b$, such that $f^s(c) \geqq (\leqq) 0$.*

Proof. Let k be such that $f(a) < k < f(b)$. The set $\{x : f(x) > k,\ a < x < b\}$ is bounded below by a so it has a g.l.b., c, distinct from a and b by the continuity of $f(x)$. Furthermore $f^s(c) \geqq 0$, since there are points $x > c$ in every neighborhood of c such that $f(x) > k$ and $f(x) \leqq k$ for $a \leqq x \leqq c$. The proof with the inequalities reversed is similar.

LEMMA 2. *There is a nondenumerable number of points such that $f^s(x) \geqq (\leqq) 0$ for $f(x)$ fulfilling the conditions of Lemma 1.*

LEMMA 3. (Quasi-Rolle's Theorem) *Let $f(x)$ be continuous on $a \leqq x \leqq b$ and let*

$f^s(x)$ exist on $a<x<b$, and let $f(a)=f(b)=0$. Then there exists a point x_1, $a<x_1<b$, such that $f^s(x_1)\geqq 0$ and a point x_2, $a<x_2<b$, such that $f^s(x_2)\leqq 0$.

Proof. If $f(x)\equiv 0$, the conclusion is immediate. If $f(x)\not\equiv 0$, there exists either c such that $f(c)>0$ or d such that $f(d)<0$ or both. By Lemma 1, there exist points x_1 and x_2, $a<x_1<c<x_2<b$ or $a<x_2<d<x_1<b$, such that $f^s(x_1)\geqq 0$ and $f^s(x_2)\leqq 0$.

THEOREM 1. (Quasi-Mean Value Theorem) *Let $f(x)$ be continuous on $a\leqq x_2\leqq b$, and let $f^s(x)$ exist on $a<x<b$. Then there exist points x_1 and x_2, $a<x_1<b$, $a<x_2<b$, such that*

$$f^s(x_2)\leqq\frac{f(b)-f(a)}{b-a}\leqq f^s(x_1).$$

Proof. This follows from Lemma 3 in a manner analogous to the proof of the Mean Value Theorem from Rolle's theorem.

THEOREM 2. *Let $f(x)$ and $f^s(x)$ be continuous on $a<x<b$. Then $f'(x)$ exists and $f'(x)=f^s(x)$.*

Proof. For h sufficiently small ($a<x+h<b$), by the previous theorem, there exist x_1 and x_2 strictly between x and $x+h$ such that

$$f^s(x_2)\leqq\frac{f(x+h)-f(x)}{h}\leqq f^s(x_1).$$

If strict inequalities hold, we apply the intermediate value theorem for continuous functions. In any case there exists x_3 strictly between x and $x+h$ such that

$$f^s(x_3)=\frac{f(x+h)-f(x)}{h}.$$

Taking the limit of both sides as $h\to 0$, knowing that the limit of the left side exists, one obtains $f^s(x)=f'(x)$. The following even stronger theorem can be proven.

THEOREM 3. *Let $f^s(x)$ be continuous at a point a and let $f(x)$ be continuous in a neighborhood of a; then $f'(a)$ exists and $f'(a)=f^s(a)$.*

Proof. For $\epsilon>0$, there exists N_a such that if $x\in N_a$, $f(x)$ is continuous and $f^s(a)-\epsilon<f^s(x)<f^s(a)+\epsilon$. By Theorem 1, there exist x_1 and x_2 strictly between a and $a+h$ such that

$$f^s(x_2)\leqq\frac{f(a+h)-f(a)}{h}\leqq f^s(x_1)$$

for N_a such that $(a+h)\in N_a$, $h\neq 0$. Hence

$$f^s(a)-\epsilon<\frac{f(a+h)-f(a)}{h}<f^s(a)+\epsilon.$$

The existence of $f'(a)$ follows and $f'(a)=f^s(a)$.

It is of interest that if the first symmetric derivative exists almost everywhere, then the ordinary derivative exists almost everywhere. For proof see Khintchine [3, p. 217]. For continuous functions the ordinary derivative exists everywhere the symmetric derivative exists, except, perhaps, on a set of first category. See Bruckner and Goffman [2, p. 511].

3. Relation to the Lipschitz condition. It is well known that the existence of a bounded derivative for $f(x)$ on $a<x<b$ implies that $f(x)$ satisfies a Lipschitz condition. The following theorem is the analogous theorem for the symmetric derivative.

THEOREM 4. *Let $f^s(x)$ be bounded on $a<x<b$, and let $f(x)$ be continuous on $a<x<b$. Then $f(x)$ satisfies a Lipschitz condition on $a<x<b$. That is, for x, t, $a<x<b$, $a<t<b$, there exists a constant A such that $|f(x)-f(t)| \leqq A|x-t|$, where A is independent of x and t.*

Proof. For some A, $|f^s(x)| \leqq A$, $a<x<b$. By Theorem 1,

$$-A \leqq \frac{f(x)-f(t)}{(x-t)} \leqq A, \quad (a<x<b,\ a<t<b)$$

and $|f(x)-f(t)| \leqq A|x-t|$, $(a<x<b,\ a<t<b)$.

The converse is not true, as shown by the following

Example. Let $f(x)=0$, $(-1 \leqq x \leqq 0)$; for $x=1/2^{2n}$, $x \leqq 1$ let $f(x)=0$; for $x=1/2^{2n-1}$, $x \leqq 1$, let $f(x)=1/2^{2n}$. Connect successive points $(1/2^n, f(1/2^n))$ by straight lines to define the function at other points on $0 \leqq x \leqq 1$.

For all x and t in the interval $(-1, +1)$, $|f(x)-f(t)| \leqq |x-t|$. Clearly, $f^s(0)$ does not exist.

In the above example $f(x)$ crosses the line $y=x/4$ an infinite number of times.

This example suggests the following definition and theorem.

DEFINITION: *$f(x)$ is said to satisfy condition (F) at a point c if $f(x)$ crosses every straight line m through $(c, f(c))$ at most a finite number of times in some neighborhood N_c^m.*

THEOREM 5. *Let $f(x)$ satisfy Lipschitz condition in $a<x<b$ and let condition (F) be satisfied for each x. Then $f^s(x)$ exists and is bounded for $a<x<b$.*

Proof. We will show that if $f^s(c)$ does not exist for some c, $a<c<b$, then there is a line through $(c, f(c))$ such that $f(x)$ crosses this line an infinite number of times in every N_c. If $f^s(c)$ does not exist, either the left hand or right hand derivative does not exist [5, p. 22]. Consider the second case, the first case being similar. The Lipschitz condition implies that the Dini derivatives $f^+(c)$ and $f_+(c)$ are bounded. See Boas [1, p. 113]. Set $f^+(c)=M$ and $f_+(c)=m$. There exists $\epsilon>0$ such that $M-m>4\epsilon$. In every neighborhood of c, there are points s, $(s>c)$ and t, $(t>c)$ such that

(1) $f(s) > (M-\epsilon)(s-c)+f(c)$ and (2) $f(t) < (m+\epsilon)(t-c)+f(c)$.

Let $s_1(c<s_1<b)$ be one such point satisfying (1) and let $t_1(c<t_1<s_1)$ satisfy (2), followed by $s_2(c<s_2<t_1)$ satisfying (1) and then by $t_2(c<t_2<s_2)$ satisfying (2). This process can be continued indefinitely. By an application of the intermediate value theorem for continuous functions we obtain an infinite number of crossing points of

$$y = (m + 2\epsilon)(x - c) + f(c).$$

From the Lipschitz condition, it follows that $f^s(x)$ is bounded in $a<x<b$ and the theorem is proved.

Condition (F) is not a necessary condition. Consider $G(x)=f(x)-f(-x)$ where $f(x)$ is the function defined in the previous example.

4. Some further remarks. At a relative maximum within an open interval $f^s(x)$ need not be 0, consider

$$f(x) = x - |2x|; \qquad f^s(0) = 1,$$

and this is a relative maximum at 0.

For a further discussion of Dini derivatives including a quasi-mean value theorem see [1]. For a discussion of conditions weaker than the Lipschitz condition but stronger than continuity see [4].

Finally, I would like to thank F. Brooks, R. Haines, and F. Leetch for their valuable suggestions in regard to this paper.

Most of the above research was done at Kent State University.

ON A MEAN VALUE PROPERTY FOR SOLUTIONS OF A WAVE EQUATION

S. C. CHU, Bellcomm, Washington, D. C. (Now at University of Delaware)

In [1] Epstein showed that if D is "a simply connected plane domain of finite area and t a point of D such that, for every function u harmonic in D and integrable over D, the mean value of u over the area of D equals $u(t)$, then D is a disc and t is its center." This result completes a triple of properties for harmonic functions; the other two being that if $u(x, y)$ is harmonic then it has the mean value property over a disc, and if $u(x, y)$ is continuous and has the mean value property over a disc, then it is harmonic in the disc.

There is an analogous triplet for functions which are solutions of the one-dimensional wave equation. It is well known that (see [2]) a function $u(x, t)$

which is, say, twice continuously differentiable in a domain Ω, satisfies the wave equation

$$u_{xx} = u_{tt}, \tag{1}$$

in Ω, if and only if u satisfies the difference equation

$$u(A) + u(C) = u(B) + u(D), \tag{2}$$

where A, B, C, and D are the vertices of any rectangle contained in Ω, whose sides are characteristics (i.e., lines with equations $x+t=$constant or $x-t=$constant).

The purpose of this note is to give an analogue of Epstein's theorem, and thereby complete the triplet.

THEOREM. *Let Q be a quadrilateral in a plane domain Ω, and let Q have vertices $A=(x_1, t_1)$, $B=(x_2, t_2)$, $C=(x_3, t_3)$, and $D=(x_4, t_4)$. If every function $u(x, t)$ which satisfies the wave equation* (1) *in Ω also satisfies the difference equation* (2), *at the vertices of Q, then Q is a rectangle with sides which are characteristic.*

Proof. It can be assumed without loss that $D=(x_4, t_4)=(0, 0)$. The functions $x+t$ and $x-t$ are certainly solutions of (1). Substitution of these two functions into equation (2), and addition and subtraction of the two resulting equations give

$$x_3 = x_2 - x_1, \tag{3}$$

$$t_3 = t_2 - t_1. \tag{4}$$

Furthermore, the functions $(x+t)^2$ and $(x-t)^2$ are also solutions of (1). Substitution of these functions into equation (2) yields

$$(x_1 + t_1)^2 + (x_3 + t_3)^2 - (x_2 + t_2)^2 = 0,$$
$$(x_1 - t_1)^2 + (x_3 - t_3)^2 - (x_2 - t_2)^2 = 0.$$

By applying the relations (3) and (4) to the last pair of equations, one obtains

$$(x_1 + t_1)(x_1 + t_1 - x_2 - t_2) = 0, \tag{5}$$

$$(x_1 - t_1)(x_1 - t_1 - x_2 + t_2) = 0. \tag{6}$$

Equation (5) implies that either

$$x_1 = -t_1, \tag{7}$$

or

$$x_1 - x_2 = t_2 - t_1. \tag{8}$$

If (7) is true, then $x_1 \neq t_1$ (otherwise, $x_1=t_1=0$, and Q degenerates to a triangle). Therefore, (6) gives $x_1-t_1-x_2+t_2=0$, or

$$t_2 = x_2 - 2x_1. \tag{9}$$

If (8) is true, then $x_2-x_1 \neq t_2-t_1$ (otherwise $x_2=x_1$, $t_2=t_1$). Therefore, (6) gives

(10) $$t_1 = x_1$$

and hence

(11) $$t_2 = 2x_1 - x_2.$$

One has, therefore, from equations (3), (4), (7), (9), (10), and (11) either

$$t_1 = -x_1, \quad t_2 = x_2 - 2x_1, \quad x_3 = x_2 - x_1, \quad t_3 = x_2 - x_1,$$

or

$$t_1 = x_1, \quad t_2 = 2x_1 - x_2, \quad x_3 = x_2 - x_1, \quad t_3 = x_1 - x_2.$$

This means that the four vertices of Q are either

$$(0, 0), \quad (x_1, -x_1), \quad (x_2, x_2 - 2x_1), \quad (x_2 - x_1, x_2 - x_1),$$

or

$$(0, 0), \quad (x_1, x_1), \quad (x_2, 2x_1 - x_2), \quad (x_2 - x_1, x_1 - x_2).$$

In both cases, each adjacent pair of vertices lies on a line with equation $x+t=$constant or $x-t=$constant. This is the desired result.

SOME ESTIMATES FOR $\sigma(n)$

R. L. DUNCAN, Lock Haven State College

Let $H(n)=1+\frac{1}{2}+\cdots+1/n$. Using the estimate $H(n)=O(\log n)$, Cohen [1] has shown that

(1) $$\sigma(n) = O(n \log n),$$

where $\sigma(n)$ is the sum of the divisors of n. His proof consists of the observation that

(2) $$\sigma(n) = \sum_{d/n} d = n \sum_{d/n} 1/d \leqq nH(n).$$

Our purpose here is to refine this observation to obtain improvements in (1). To do this we use the explicit estimate

(3) $$H(n) \leqq 1 + \log n.$$

The following proof of (3) requires only (see [2])

(4) $$\left(1 + \frac{1}{n}\right)^{n+1} \geqq e.$$

If we assume (3), then

$$H(n+1) = H(n) + \frac{1}{n+1} \leqq 1 + \log n + \frac{1}{n+1}$$
$$= 1 + \log (n+1) + \frac{1}{n+1}\left[1 - \log\left(1 + \frac{1}{n}\right)^{n+1}\right]$$
$$\leqq 1 + \log (n+1) \quad \text{by} \quad (4).$$

Since $H(1) \leqq 1 + \log 1$, the desired result (3) is true for every positive integer n by mathematical induction. The results (2) and (3) imply the explicit estimate

$$\sigma(n) \leqq n \log n + n \tag{5}$$

which implies (1).

We now refine (2) to obtain sharper estimates for $\sigma(n)$. It is obvious that

$$\sigma(n) = n \sum_{d/n} \frac{1}{d} \leqq n \sum_{k=1}^{d(n)} \frac{1}{k} = nH(d(n)), \tag{6}$$

where $d(n)$ is the number of positive divisors of n. It follows from (3) and (6) that

$$\sigma(n) \leqq n \log d(n) + n \tag{7}$$

and this improves (5). Since $\log d(n) = o(\log n)$ [3, Theorem 315], (7) implies that

$$\sigma(n) = o(n \log n) \tag{8}$$

and this improves (1).

We now establish several further explicit estimates for $\sigma(n)$. If p^α is the highest power of p which divides n, then

$$\sigma(n) = n \prod_{p/n}\left(1 + \frac{1}{p} + \cdots + \frac{1}{p^\alpha}\right) < n \prod_{p/n}\left(1 - \frac{1}{p}\right)^{-1}$$
$$= n \prod_{p/n}\left(1 + \frac{1}{p}\right)\left(1 - \frac{1}{p^2}\right)^{-1}.$$

Since $\zeta(2) = \prod_p (1 - (1/p^2))^{-1}$, we have

$$\sigma(n) < \zeta(2) n \prod_{p/n}\left(1 + \frac{1}{p}\right). \tag{9}$$

If we let n be the rth power of the product of the first r primes and let $r \to \infty$, a similar argument shows that

$$\limsup_{n\to\infty} \frac{\sigma(n)}{n} \prod_{p/n}\left(1 + \frac{1}{p}\right)^{-1} = \zeta(2).$$

It should be observed in conjunction with (9) that

$$\sigma(n) \geqq n \prod_{p/n}\left(1+\frac{1}{p}\right) \tag{10}$$

with equality holding if and only if n is square-free. Thus the constants in (9) and (10) are the best possible. By (9) we have

$$\sigma(n) < \zeta(2)n \sum_{d/n} \frac{|\mu(d)|}{d} \leqq \zeta(2)nH(2^{\omega(n)}),$$

where $\omega(n)$ is the number of distinct prime divisors of n. It now follows from (3) that

$$\sigma(n) < \zeta(2)n[1 + \omega(n) \log 2]. \tag{11}$$

Also, since $\zeta(2) = \pi^2/6 < 10/6$ and $\log 2 < 7/10$, we have

$$\sigma(n) < \frac{n}{6}[7\omega(n) + 10] \tag{12}$$

and this is virtually as good as (11).

We conclude with a simple proof that

$$\sigma(n) = O(n \log \log n). \tag{13}$$

If $r = \omega(n)$ and p_r is the rth prime, then

$$\log \prod_{p/n}\left(1+\frac{1}{p}\right) = \sum_{p/n} \log\left(1+\frac{1}{p}\right) \leqq \sum_{p/n} \frac{1}{p}$$

$$\leqq \sum_{p \leqq p_r} \frac{1}{p} = \log \log p_r + O(1).$$

Hence

$$\prod_{p/n}\left(1+\frac{1}{p}\right) = O(\log p_r) = O(\log r) = O(\log \log n).$$

The desired result now follows from (9). The above proof relies on Theorems 9 and 427 of Hardy and Wright [3] and the trivial fact that $\omega(n) = O(\log n)$.

A COUNTEREXAMPLE ON INDEPENDENT EVENTS

E. L. Crow, Environmental Science Services Administration, Boulder, Colorado

In probability theory the events A, B, and C are said to be independent (or statistically independent) if

$$(1)\quad P[AB] = P[A]P[B], \qquad P[AC] = P[A]P[C], \qquad P[BC] = P[B]P[C],$$

$$(2)\quad P[ABC] = P[A]P[B]P[C].$$

Examples are given in the texts by Cramér [1], Fisz [2], and Parzen [5] which show that (1) does not imply (2). Cramér's example, attributed to S. Bernstein, is a three-dimensional distribution of random variables (X, Y, Z) in which each of the four points (1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 1) carries the probability $\frac{1}{4}$. It is then easily verified that

$$\begin{aligned} P[X = 1] &= P[Y = 1] = P[Z = 1] = \tfrac{1}{2}, \\ P[X = 1, Y = 1] &= \tfrac{1}{4} = P[X = 1]P[Y = 1], \\ P[X = 1, Z = 1] &= \tfrac{1}{4} = P[X = 1]P[Z = 1], \\ P[Y = 1, Z = 1] &= \tfrac{1}{4} = P[Y = 1]P[Z = 1], \end{aligned}$$

but $P[X=1, Y=1, Z=1] = \frac{1}{4} \neq P[X=1]P[Y=1]P[Z=1]$.

As the fullness of the definition suggests, it is also true that (2) does not imply (1). This is not specifically pointed out in any of the texts I have examined [6], and it seems desirable to give an example demonstrating this proposition. Let (X, Y, Z) have the locations (1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 0), and (1, 1, 1) with the probabilities $\frac{1}{8}$, $\frac{1}{8}$, $\frac{3}{8}$, $\frac{2}{8}$, and $\frac{1}{8}$ respectively. Then

$$\begin{aligned} P[X = 1] &= P[Y = 1] = P[Z = 1] = \tfrac{1}{2}, \\ P[X = 1, Y = 1, Z = 1] &= \tfrac{1}{8} = P[X = 1]P[Y = 1]P[Z = 1], \end{aligned}$$

but

$$\begin{aligned} P[X = 1, Y = 1] &= \tfrac{3}{8} \neq P[X = 1]P[Y = 1], \\ P[X = 1, Z = 1] &= \tfrac{1}{8} \neq P[X = 1]P[Z = 1], \\ P[Y = 1, Z = 1] &= \tfrac{1}{8} \neq P[Y = 1]P[Z = 1]. \end{aligned}$$

Hence (2) does not imply (1).

Fisz and Parzen express Bernstein's example in terms of urn models; this has the advantage of eliminating reference to random variables. The latter example above can also be so expressed. Thus, we consider drawing one ball from an urn with 1 red ball, 1 blue, 3 yellow, 2 purple, and 1 white. We consider all balls to be equally probable. Let A be the event of drawing a red or a purple or a white ball, B the event of drawing a blue or a purple or a white ball, and C the event of drawing a yellow or a white ball. Then (2) holds but not (1).

Lancaster [4] recently generalized Bernstein's example to any number of

points and any number of dimensions. Geisser and Mantel [3] gave a useful continuous example.

THE ALGEBRAIC DERIVATIVE OF MIKUSIŃSKI

R. G. Buschman, State University of New York at Buffalo

Jan Mikusiński has introduced into his operational calculus [2] an *algebraic derivative* which corresponds to differentiation with respect to the operator s. The operator D is defined initially by

$$Da = \{-ta(t)\};$$

that is, for locally integrable functions it corresponds to multiplication of the functional values by $-t$. In the field of operators, D is shown to produce the usual differentiation formulas for sums, differences products, and quotients. Further, if the operator is a rational function of s, then D corresponds to d/ds.

In order to introduce meaning for algebraic derivatives of other than integral order, it is convenient to reconsider the form, using $-D$ as the operator; thus

$$(-D)^n a = \{t^n a(t)\}.$$

This corresponds to the situation for Laplace transforms, where we have

$$\{t^n F(t)\} = (-d/ds)^n f(s),$$

$$\{t^{-n} F(t)\} = \int_s^\infty \cdots \int_s^\infty f(u)(du)^n.$$

Further, the correspondence is preserved if we introduce the fractional integral operator:

$$K^\alpha f(s) = [1/\Gamma(\alpha)] \int_s^\infty (u - s)^{\alpha-1} f(u)\,du, \qquad (\alpha > 0),$$

then $(-D) = K^{-1}$ and $(-D)^\beta = (-D)^n K^{n-\beta}$, where n is chosen such that $n - \beta > 0$. This allows the introduction of algebraic fractional integrals and derivatives

consistent with the algebraic derivative. Thus, if we take

$$K^{\alpha}a = \{t^{-\alpha}a(t)\},$$

we have an analog to the operational calculus relation $s^{-\alpha}a = \{I^{\alpha}a(t)\}$, where

$$I^{\alpha}a(t) = [1/\Gamma(\alpha)]\int_0^t (t-u)^{\alpha-1}a(u)du.$$

Tables of fractional integrals are available [1].

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, Louisiana State University; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P. O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before October 31, 1967. ***Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.***

E 1995. *Proposed by L. J. Mordell, St. Johns College, Cambridge, England*

$ABCD$ is a tetrahedron T, and P is any point of T. The circumsphere of T has center O and radius R, and a concentric sphere of radius $R_1 \geqq \frac{1}{2}R$, cuts OA in A_1, etc. Let $|P|$ be the least of the distances PA_1, PB_1, PC_1, PD_1. Prove that $|P| \leqq R_1$, with equality only if $R_1 = \frac{1}{2}R$ and P is distant $\frac{1}{2}R$ from A_1, B_1, C_1 or D_1.

A similar result holds for a simplex and then, when $R_1 = R$, it is due to M. J. Godwin, J. London Math. Soc., 40(1965)699.

$$\left\{\prod_{i=0}^{n-1}(m^n - m^i)\right\}/n!.$$

E 2005. *Proposed by W. A. McWorter, University of British Columbia*

Let $p_1, \cdots, p_t$ be distinct primes and n a positive integer, and let $k=p_1 \cdots p_t$. Show that there exist nonnegative integers $a_1, \cdots, a_t$ such that

$$\sum_{i=1}^{t} a_i p_i = \binom{kn-1}{k-1} - 1.$$

SOLUTIONS OF ELEMENTARY PROBLEMS

Inscribed Regular Polygon of 13 Sides

E 1835 [1965, 1128]. *Proposed by Tudor Zamfirescu, Bucharest, Rumania*

A circumference is given in the plane. Show that the construction of an inscribed regular polygon with 13 sides is possible using a straightedge and an angle trisector.

Solution by Michael Goldberg, Washington, D.C. It is known that all Euclidean constructions can be performed with the straight edge alone, if a circumference and its center are given. Since the center is not given, it can be found by means of the trisector. Taking any two points of the circumference, trisect an angle inscribed in this arc. Then the intersections of the joins of the original two points with the trisection points on the arc determine a diametral line. Another diametral line, determined similarly, locates the center of the circumference.

The problem requires the construction of the 12 imaginary 13th roots of unity. The method is suggested in Problem 3, p. 40, of Dickson, *Theory of Equa-*

tions. Let these roots be $R, R^2, \cdots, R^{12}$. If we take the sixth power of a root to obtain the next root, the 12 roots have the sequence $R, R^6, R^{10}, R^8, R^9, R^2, R^{12}, R^7, R^3, R^5, R^4, R^{11}$. Taking every third term, let

$$z_1 = R + R^8 + R^{12} + R^5, \qquad z_2 = R^6 + R^9 + R^7 + R^4,$$
$$z_3 = R^{10} + R^2 + R^3 + R^{11}.$$

Then

$$z_1 + z_2 + z_3 = -1,$$
$$z_2z_1 + z_3z_2 + z_1z_3 = 4(R + R^2 + \cdots + R^{12}) = -4,$$
$$z_1z_2z_3 = 4 + 5(R + R^2 + \cdots + R^{12}) = 4 - 5 = -1.$$

Then z_1, z_2, z_3 are the roots of the cubic equation $z^3+z^2-4z+1=0$. The roots of this cubic are obtained graphically by means of the Cardan formulas (Dickson, Theory of Equations, pp. 46–48) by employing Euclidean constructions in conjunction with the angle trisector.

Hence R, R^8, R^{12}, R^5 are the roots of the quartic equation $w^4-z_1w^3+z_2w^2-z_3w+1=0$. The roots of this equation are obtained by use of the Descartes formulas (pp. 52–54). Hence R and the other roots are constructible.

A Limit Which Is Not the Derivative

E 1852 [1966, 83]. *Proposed by Stephen Haines and L. F. Leetch, Bowling Green State University, Ohio*

If $F^*(x) = \lim_{h\to 0}\{F(x+h) - F(x-h)\}/2h$, prove or disprove the following statement: If F and F^* are continuous at x, then F' exists at x and $F'(x) = F^*(x)$.

Solution by Freshman Honors Students, University of Connecticut. As a counterexample we present a function F, such that F and F^* are continuous at $x=0$, but F' does not exist at $x=0$. Define F as follows: $F(\pm 1/n) = 1/n$ for all positive integers n, $F(x)=0$ for all other real numbers x. It is immediately seen that F^* is continuous and in fact $F^*(x)\equiv 0$ for all real x, F is continuous at $x=0$, yet F' does not exist at $x=0$.

Also solved by R. D. Berlin, C. R. Conniff, Erhard Heil (W. Germany), Elaine Rakshys, Jürg Rätz (Switzerland), Simeon Reich (Israel), Francis Siwiec, Al Somayajulu, and the proposers.

Solution of Simultaneous Quadratic Equations

E 1855 [1966, 198]. *Proposed by L. M. Young, San Fernando Valley State College*

Let λ be a given (real or complex) number. Solve the system:

$$x_{n+1} = x_n^2 - \lambda \quad (n = 1, 2, 3, 4),$$

where $x_5 = x_1$, subject to the condition $x_3 \neq x_1$.

Solution by R. C. Lyness, Blackpool, England. Let x_1 and x_3 be the roots of $x^2 - px + q = 0$ and put $s_r = x_1^r + x_3^r$. From the two equalities

$$x_3 = x_1^4 - 2\lambda x_1^2 + \lambda^2 - \lambda, \qquad x_1 = x_3^4 - 2\lambda x_3^2 + \lambda^2 - \lambda,$$

we have (adding) $s_1 = s_4 - 2\lambda s_2 + 2\lambda(\lambda - 1)$, and (subtracting and dividing by $(x_1 - x_3)$), $-1 = s_1 s_2 - 2\lambda s_1$. Substitution for s_r in terms of p and q gives $q = (p^3 - 2\lambda p + 1)/2p$ and, upon eliminating q,

$$p^6 - 4\lambda p^4 + 4p^3 + 4\lambda p^2 - 1 = 0.$$

This is a cubic in $y = p - 1/p$.

We therefore solve $y^3 - (4\lambda - 3)y + 4 = 0$ for y, then $p^2 - yp - 1 = 0$ for p and finally $x^2 - px + (p^3 - 2\lambda p + 1)/2p = 0$ for x_1 and x_3.

Also solved by L. E. Ward, and by W. B. Tuel, Jr.

Roots of a Transcendental Equation

E 1857 [1966, 198]. *Proposed by Steven Rosencrans and James Potter, Massachusetts Institute of Technology*

Show that the solutions λ of $\tan \lambda = a\lambda/(\lambda^2 + c)$, where a is real and c is positive, are either real or (pure) imaginary.

I. *Solution by W. G. Tuel, Jr., San Jose, California.* Let $\lambda = s + it$, where s and t are real. Then the given equation may be broken into

$$\frac{\tan s \operatorname{sech}^2 t}{1 + \tan^2 s \tanh^2 t} = \frac{as^2(s^2 + t^2 + c)}{(s^2 - t^2 + c)^2 + 4s^2t^2}, \tag{1}$$

$$\frac{\tanh t \sec^2 s}{1 + \tan^2 s \tanh^2 t} = \frac{at(c - s^2 - t^2)}{(s^2 - t^2 + c)^2 + 4s^2t^2}, \tag{2}$$

by equating real and imaginary parts. Assume $st \neq 0$. Then upon division (1) and (2) give

$$\frac{\tan s \operatorname{sech}^2 t}{\tanh t \sec^2 s} = \frac{s}{t}\left[\frac{s^2 + t^2 + c}{c - s^2 - t^2}\right],$$

$$\left(\frac{\sin 2s}{2s}\right) \Big/ \left(\frac{\sinh 2t}{2t}\right) = \frac{c + (s^2 + t^2)}{c - (s^2 + t^2)}. \tag{3}$$

But, for all $s, t \neq 0$, the left member of (3) is less than 1, while the right member is greater than 1. This contradiction proves $st = 0$, which implies the statement of the problem.

II. *Solution by Martin Ziegler, Technische Hochschule, Clausthal-Zellerfeld, Germany.* Suppose a, c to be real. Then every solution of $\tan\lambda = a\lambda/(\lambda^2+c)$ with λ^2 nonreal must be a zero of $F(\lambda) \equiv (\lambda^2+c)\sin\lambda - a\lambda\cos\lambda$. We shall show that, with the condition $c+a^2/4 \geqq 0$, $F(\lambda)$ has only zeros with λ^2 real. Consider the eigenvalue problem for $y = y(x;\lambda)$ in $0 \leqq x \leqq 1$:

$$(1)\quad y'' + \lambda^2 y = 0, \qquad (2)\quad U_0[y] \equiv y'(0) - b_0 y(0) = 0,$$

$$(3)\quad U_1[y] \equiv y'(1) + b_1 y(1) = 0,$$

with real b_0, b_1. It is well known that (1) – (3) is a self-adjoint and normal problem with only real eigenvalues λ^2. (Cf. L. Collatz, *Eigenwertaufgaben mit technischen Anwendungen*, Leipzig 1949, p. 54.) On the other hand, direct calculation shows for the solutions of (1), $y(x;\lambda) = \alpha\cos\lambda x + \beta\sin\lambda x$, that (2), (3) is non-trivially solvable if and only if

$$G(\lambda) \equiv (\lambda^2 - b_0 b_1)\sin\lambda - (b_0 + b_1)\lambda\cos\lambda = 0.$$

A solution $F(\lambda) \equiv G(\lambda)$ exists if b_0, b_1 are the two solutions of $b^2 - ab - c = 0$, and b_0, b_1 are real provided $c+a^2/4 \geqq 0$, which gives some extension of the conditions, $c > 0$, a real, in the problem.

Also solved by G. Di Antonio, and by Louise S. Grinstein.

M. S. Klamkin notes that the present problem is a slight extension of E 1295 [1958, 450], where the first solution is similar to I above. (Note a slight misprint where the denominator on the right of the first equation should be $[1+m^2(a^2-b^2)]^2+4m^4a^2b^2$.)

System with Restricted Commutativity of Addition

E 1858 [1966, 198]. *Proposed by S. E. Dickson, University of Nebraska*

Assume the usual properties of the real numbers except for commutativity of addition. Given that the equation $x+y = y+x$ holds for real numbers x and y less than 10^{-26} apart, show that this latter restriction can be removed.

II. *Solution by J. L. Brown, Jr., Pennsylvania State University.* Let x', y' be arbitrary *distinct* real numbers and let $a = 10^{30}(x'-y')$. Since $a \neq 0$, the equations $ax = x'$ and $ay = y'$ have unique real solutions x and y respectively. Moreover, $a(x-y) = ax - ay = x' - y'$, so that $x - y = 10^{-30} < 10^{-26}$. Therefore

$$x' + y' = ax + ay = a(x+y) = a(y+x) = ay + ax = y' + x'.$$

Since commutativity is obvious when $y' = x'$, we have that addition is commutative for any pair x', y' of real numbers.

Also solved by J. C. Abad, I. K. Abruob, Merrill Barneby, S. I. Brown, J. P. Celenza, C. W. Dodge, A. H. Durfee, G. F. Feissner & V. W. Goodman, Arne Garness & G. A. Heuer, E. D. Gingerich, Anton Glaser, J. E. Homer, Jr., H. D. Junghenn, Erwin Just, E. S. Langford, Arthur Lieberman, D. C. B. Marsh, Liselotte Miller, Norman Miller, D. E. Nixon & J. P. Thomas, Howard Penn, Robert Prener, Stanley Rabinowitz, Azriel Rosenfeld, G. F. Schumm, D. L. Silverman, Robin Spital, L. A. Steen, E. J. Wegman, John Wessner, P. C. Yang, and K. L. Yocom, several of whom note that the result is already contained in E 1812 [1967, 199].

Characteristic Roots of a Matrix

E 1859 [1966, 198]. *Proposed by Judith H. Hallman, University of North Carolina and Western Electric Company*

Let $k_1, k_2, \cdots, k_n$ be any real numbers different from zero, and let $A=(a_{ij})$ be the matrix $a_{ij}=k_i/k_j$. Find the n characteristic roots of A.

III. *Solution by Judith Richman, Drexel Institute of Technology.* The rows of the matrix A are proportional to each other, so that its rank is 1. It follows that $n-1$ of the characteristic roots are zeros. Since the diagonal elements of A are unity, the trace is n, and the sum of the characteristic roots is n. Thus the roots are 0 of multiplicity $n-1$, and n.

Also solved by H. D. Abramson, W. R. Allaway, D. A. Blaeuer, J. L. Brenner, Martin Brown, R. B. S. Brooks & E. M. Scheuer, J. F. Burke, John Burslem, J. P. Celenza, P. L. Claypool, Red Cougar, R. W. Feldman, R. O. Fisher, A. V. Geramita, M. G. Greening (Australia), Eldon Hansen, J. E. Homer, Jr., Edward Hook, M. S. Klamkin, J. D. E. Konhauser, J. A. Lambert (Australia), E. S. Langford, T. J. Lee, M. W. Legg, Arthur Lieberman, D. C. B. Marsh, C. P. McCarty, Lieselotte Miller, M. G. Murdeshwar, Dave Nixon, Stanton Philipp, Stanley Rabinowitz, Steven Russ M.S.R.K. Sastry, Perry Scheinok, A. J. Schneider, R. Sivaramakrishnan (India), J. B. Skinner, Sidney Spital, Rory Thompson, W. G. Tuel, Jr., John Wessner, J. E. Wilkins, Jr., H. H. Wong, and K. L. Yocom.

Four Trigonometric Inequalities

E 1861 [1966, 199]. *Proposed by T. R. Curry, Bay Shore, N. Y.*

Given a triangle ABC with the usual notation for sides, angles, area, circumradius and inradius, prove the following inequalities, with equality holding if and only if the triangle is equilateral:

$$(1)\qquad 4\Delta\sqrt{3} \leqq \frac{9abc}{a+b+c}, \qquad (2)\qquad 2\Delta\sqrt{3} \leqq 9rR,$$

$$(3)\qquad \cot A + \cot B + \cot C \geqq \frac{(a^2+b^2+c^2)(a+b+c)\sqrt{3}}{9abc}.$$

$$(4)\qquad \csc A + \csc B + \csc C \geqq 2\sqrt{3}.$$

Solution by Leon Bankoff, Los Angeles, California. In any triangle, as is well known, $\sum \sin A$ is a maximum when $A=B=C$, so that $\sum \sin A \leqq 3\sqrt{3}/2$ or

$$(*)\qquad a+b+c \leqq 3R\sqrt{3}.$$

From (*) and $R=abc/4\Delta$ we have at once (1). Again, (*) and $2\Delta=r(a+b+c)$ give (2).

We have $2R\sum ab\cos C = abc\sum \cot A$ in which the left member may be replaced, by the law of cosines, to give $R(a^2+b^2+c^2)=abc\sum \cot A$, which with (*), proves (3).

Since $(a+b+c)(1/a+1/b+1/c) \geqq 9$, and $\sum \csc A = 2R(1/a+1/b+1/c)$, (4) follows at once, again using (*).

Also solved by A. N. Aheart, Louise S. Grinstein, M. G. Greening (Australia), M. H. Hayamizu, M. S. Klamkin, D. C. B. Marsh, Norman Miller, Stanley Rabinowitz, Stanton Philipp, Simeon Reich (Israel), M. S. R. K. Sastry, R. Sivaramakrishnan (India), Stephen Spindler, Sidney Spital, J. L. Standig, P. D. Thomas, and J. Wesley.

Radius of Curvature

E 1863 [1966, 199]. *Proposed by R. G. Albert, West Newton, Mass.*

The size and shape of a conic with positive eccentricity are determined by two parameters, the distance d from a focus to the nearest directrix and the eccentricity e. Evaluate the radius of the osculating circle at a vertex as a function of d and e.

Solution by P. D. Thomas, Naval Research Laboratory, Washington, D.C. It is known that the radius of curvature of a conic at a vertex is equal to the length of the semilatus rectum. But the length of the latus rectum is $2de$, whence the desired radius equals de.

Otherwise: the polar equation of the conic in terms of d and e is $r=de/(1+e\cos\theta)$. The radius of curvature is given by

$$R = (r^2 + r'^2)^{3/2}/(r^2 + 2r'^2 - rr'') = de(1 + 2e\cos\theta + e^2)^{3/2}/(1 + e\cos\theta)^3$$

which becomes, for a vertex ($\theta=0, \pi$), $R=de$.

Also solved by Michael Goldberg, P. F. Hultquist, J. D. E. Konhauser, R. C. Lyness (England), D. C. B. Marsh, Liselotte Miller, C. S. Ogilvy, Simeon Reich (Israel), Robin Robinson, Perry Scheinok, Sidney Spital, W. G. Tuel, Jr., W. K. Viertel, and Charles Wexler.

Group Whose Elements Satisfy $A^2 = I$

E 1864 [1966, 200]. *Proposed by R. E. Mikhel, Tri-State College, Angola, Ind.*

If G_i is an abelian group of involutoric matrices ($A^2=I$) prove that the order of G_i is of the form 2^n.

Solution by Douglas Lind, University of Virginia. Suppose a prime p is a divisor of the order of G_i. By Cauchy's theorem for abelian groups, there is an $A \in G_i$ whose order is p. But $A^2=I$, so that $p \leqq 2$, implying the result.

Also solved by I. K. Abruob, D. P. Ambrose, Joe Beckely, D. C. Eckert, R. C. Freiwald, L. D. Haugh, G. A. Heuer, J. E. Homer, Jr., Roman Kaluzniacki, M. S. Klamkin, D. C. B. Marsh, J. M. Petro, Simeon Reich (Israel), Stephen Rhodes, Michael Schulz, R. Sivaramakrishnan (India), and Dalton Tarwater.

Notes. Without appropriate restrictions the statement is false, for if F is an infinite field of characteristic 2, then

$$\left\{\begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} : x \in F\right\}$$

is an infinite abelian group of involutoric matrices. Perhaps the notation G_i implies a finite group.—*Petro.*

The assumption that G is abelian is superfluous; it follows from $(AB)^2 = I = A^2B^2$—*Abruob.*

The problem is stated and solved in V. I. Smirnov, *Linear Algebra and Group Theory*, ex. 17, p. 377. It also is a special case ($p=2$) of a theorem on p. 129 of Paley and Weichsel, *A First Course in Abstract Algebra—Homer.*

Smallest Circle Containing n Given Points

E 1866 [1966, 309]. *Proposed by Michael Fried, University of Michigan*

Given n points in the Euclidean plane. Find a ruler and compass construction for the smallest circle containing these n points.

Solution by C. B. A. Peck, Ordnance Research Laboratory, State College, Pa. If a circle contains the n points and does not pass through any of them, it can be replaced by a smaller concentric circle containing the n points and passing through at least one of them; call the desired circle O and this point A. If a circle passes through A, contains the n points and does not pass through another of them, it can be replaced by a smaller circle containing the n and tangent to the first circle at A; thus O passes through two of the n points; call them A and B. If a circle passes through A and B, contains the n points and does not pass through any other of them, it can be replaced by a smaller circle containing the n points and passing through A and B, *unless* A and B are on the same diameter of the first circle. Therefore, either O passes through three of the n points or O has two of them at opposite ends of a diameter. Ruler and compass constructions of the circles determined by these conditions are routine. The trick is to do it efficiently.

Also solved by D. J. G. Baron, Michael Goldberg, Andrew Jarosak, Norman Miller, W. L. Mrozek, and Oswald Wyler.

Mrozek notes that it is shown in Rademacher and Toeplitz, *The Enjoyment of Mathematics*, 1957, pp. 103–110, that the desired circle is unique, has the properties described above, and has radius no greater than $(d/3)\sqrt{3}$, where d is the largest distance between any two of the points of the set.

An Inequality for the Inverse Tangent

E 1867 [1966, 309]. *Proposed by R. E. Shafer, Lawrence Radiation Laboratory*

Show that for $x>0$,

$$\tan^{-1} x > \frac{3x}{1 + 2\sqrt{1 + x^2}}.$$

I. *Solution by Louise S. Grinstein, New York, N.Y.* Direct computation gives

$$\frac{dF}{dx} = \frac{(\sqrt{1 + x^2} - 1)^2}{(1 + x^2)(1 + 2\sqrt{1 + x^2})^2},$$

where $F(x) = \tan^{-1}x - 3x/(1+2\sqrt{1+x^2})$. Now dF/dx is positive for all $x \neq 0$,

whence F is an increasing function. Since $F(0)=0$, it follows that $F(x)>0$ for $x>0$.

II. *Solution by D. C. B. Marsh, Colorado School of Mines.* It follows from $(\cos\phi-1)^2\geqq 0$ that

$$1 \geqq \frac{3+6\cos\phi}{(\cos\phi+2)^2}.$$

The desired result is obtained directly upon inetgration of the latter inequality with respect to ϕ from 0 to $\tan^{-1}x$ $(x>0)$.

III. *Solution by J. D. E. Konhauser, University of Minnesota.* The substitution $x=\tan y$ transforms the given inequality into $y>3\sin y/(\cos y+2)$, which is a special case of an inequality discussed on pp. 105–6 of D. S. Mitrinovic, *Elementary Inequalities.*

Also solved by V. S. Ananthachar (India), A. Behr, G. Di Antonio, W. G. Dotson, Jr., E. P. Emerson, Marco Ettrick & Stanley Rabinowitz, H. J. Fletcher, R. E. Giudici, P. L. Gore, H. A. Greenbaum, Robert Groover III, G. A. Heuer, A. S. Howard, J. E. Joseph & O. G. Smith, D. G. Kabe, Geoffrey Kandall, B. W. King, Kenneth Kramer, Arthur Lieberman, Beatriz Margolis, Charles McCracken, Renate McLaughlin, Lieselotte Miller, Norman Miller, N. B. Murray Larry Ortloff & John Knox, Stanton Philipp, Dante Pingenot, Joel Pitcairn, George Purdy (England), Simeon Reich (Israel), M. S. R. K. Sastry, Perry Scheinok, J. G. Slagle, Sidney Spital, J. L. ADVANCED PROBLEMS

All solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be submitted on separate, signed sheets and should be mailed before December 31, 1967. Any contributor wishing acknowledgment of his solution should include a self-addressed stamped postcard. (Solvers outside the United States omit the stamp.)

5500. *Proposed by W. A. McWorter, University of British Columbia*

Let H be a nontrivial finite group. Then there exists a finite group G in which H is properly embedded as its own normalizer in G.

5501. *Proposed by Harsh Pittie, Princeton University*

Let S be a σ-finite measure space. Prove that $L^p(S)$ is τ sequentially complete, where τ is any locally convex Hausdorff topology such that the conjugate of $L^p(S)$ under τ is L^q, $(q=p/(p-1))$.

5502. *Proposed by Roy O. Davies, The University, Leicester, England*

Is it possible for the Cauchy product $\sum_{n=1}^{\infty}c_n$ of two conditionally convergent series $\sum_{n=1}^{\infty}a_n$, $\sum_{n=1}^{\infty}b_n$ to be absolutely convergent? $(c_n=a_1b_n+a_2b_{n-1}+\cdots+a_nb_1.)$

5503. *Proposed by M. T. L. Bizley, London, England*

Prove or disprove the following conjecture. The number of lattice paths from $(0, 0)$ to (km, kn) where m, n are coprime integers and k is any integer, having just r lattice points below the line $y/x = n/m$ (not counting the endpoints) is:

$$\psi_k + \psi_{k-1}\phi_1 + \psi_{k-2}\phi_2 + \cdots + \psi_p\phi_{k-p}, \quad \text{for } (p-1)(m+n) \leqq r < p(m+n),$$

$(p = 1, 2, \cdots, k)$, where ϕ_k, ψ_k are respectively the coefficients of x^k in $\phi \equiv \exp(F_1x + F_2x^2 + \cdots) - 1$ and $\psi = 1 - \exp(-F_1x - F_2x^2 - \cdots)$, and where

$$F_j = \frac{1}{j(m+n)}\binom{jm+jn}{jm}.$$

5504. *Proposed by Erwin Just, Bronx Community College*

Let f be a function defined on $(0, 1)$ such that $f'(x) = 1$ at each point of an infinite subset of $(0, 1)$. Must there exist a point at which $|f|$ is differentiable?

5505. *Proposed by Erwin Just, Bronx Community College*

If p is a prime and $p > m^{1/2}$, prove that any group of order p^2m is not simple.

5506. *Proposed by J. D. Aczel, University of Waterloo, Canada*

Find all real functions satisfying

$$f(xy) = f(x)f(y) \qquad \text{and} \qquad f(x + k) = f(x) + f(k)$$

for all real x, y and for one real $k \neq 0$.

5507. *Proposed by B. S. Yadav, Sardar Vallabhbhai Vidyapeeth, India*

If $\{\delta_n\}$ is a sequence of real numbers such that

$$\sum_{\nu=1}^{\infty} \frac{\log \nu}{\nu^2}\left\{\sum_{k=1}^{\nu} k^2\delta_k^2\right\}^{1/2} + \sum_{\nu=1}^{\infty} \frac{\log \nu}{\nu}\left\{\sum_{k=\nu+1}^{\infty} \delta_k^2\right\}^{1/2} < \infty.$$

Prove or disprove that $\sum_{n=2}^{\infty}\delta_n^2 \log n < \infty$.

5508. *Proposed by Albert Wilansky, Lehigh University*

Let X be a topological space which has a one-point compactification Y and a two-point compactification Z such that Y and Z are homeomorphic. Show that for every natural number n, X has an n-point compactification homeomorphic with Y; and give an example of a space X with this property, where Y is Hausdorff.

5509. *Proposed by A. K. Dewdney, University of Michigan*

Prove or disprove the following statement: C is a continuous curve from the point $(0, 0)$ to the point $(n, 0)$ in R^2. Denote by $T: R^2 \to R^2$ the translation $(x, y) \to (x+1, y)$ of the plane. Then $C \cap T(C) \neq \varnothing$, i.e., the translated curve intersects the original curve at some point.

SOLUTIONS OF ADVANCED PROBLEMS

The Coefficients of $(\Sigma c_i x^i)^n$

5325 [1965, 913; 1966, 901; 1967, 329]. *Proposed by D. J. Newman, Yeshiva University, and W. E. Weissblum, AVCO Research*

Suppose $0 \leqq c_i \leqq 1$ and $\sum c_i = 2$. Prove that all the coefficients of $(\sum c_i x^i)^n$ are $\leqq \binom{n}{q}$, where $q = [n/2]$.

III. *Completion of Solution I by C. B. A. Peck, Ordnance Research Laboratory, State College, Pa.* The final inequality in Solution I [1966, 901–2] is correct only for n odd, when it is an equality. For the induction from n even to $n+1$ odd, we let $n = 2m$ and put

$$\left(\sum c_i x^i\right)^m = \sum d_i x^i$$

with

$$d_i \leqq \binom{m}{q} \quad \text{and} \quad q = [m/2].$$

$(\sum c_i x^i)^{n+1} = \sum e_i x^i$ then yields

$$e_N = \sum_{i+j+k=N} d_i d_j c_k \leqq \binom{m}{q}^2 \sum c_k = 2\binom{m}{q}^2 < \binom{2m+1}{m} = \binom{n+1}{q'}$$

with $q' = [(n+1)/2]$. To establish the last inequality consider the cases m even and m odd separately. We use the identity

$$\binom{a}{0}\binom{b}{c} + \binom{a}{1}\binom{b}{c-1} + \cdots + \binom{a}{c}\binom{b}{0} = \binom{a+b}{c}.$$

(See, e.g., Feller, *An Introduction to Probability Theory and Its Applications*, Vol. 1, equation (12.9).) For m odd,

$$2\binom{m}{q}^2 = \binom{m}{q}\binom{m}{q+1} + \binom{m}{q+1}\binom{m}{q} \leqq \binom{2m}{m} < \binom{2m+1}{m},$$

where we have used $a = b = c = m$. For m even

$$\binom{m}{q}^2 < \binom{m+1}{q}\binom{m}{q}$$

and

$$\binom{m}{q}^2 \leqq \binom{m+1}{q-1}\binom{m}{q+1} + \binom{m+1}{q+1}\binom{m}{q-1}$$

hold and thus

$$2\binom{m}{q}^2 < \binom{2m+1}{m},$$

where we have used $a=m+1$ and $b=c=m$. Since Solution I gives the induction from odd to even, starting at $n=1$, we do not need to prove the case $n=2$. However, it is simple to do so:

$$e_N = \sum_{i+j=N} c_i c_j \leqq \sum c_j = 2 = \binom{2}{1}.$$

The Sequence Function $x_n=f(x_{n+1}, x_{n+2}, \cdots)$

5348 [1965, 1136; 1966, 1131]. *Proposed by Fred Galvin, St. Paul, Minnesota*

Show that there is a function f such that for any sequence $(x_1, x_2, \cdots)$ we have $x_n=f(x_{n+1}, x_{n+2}, \cdots)$ for all but finitely many n.

Editorial Note. It has been pointed out by the proposer that the "stronger result" claimed in the printed solution is incorrect. B. L. D. Thorpe cites the following counterexample to the argument as presented. Select a well ordering in which the first element is the sequence $(2, 1, 0, 1, 0, 1, 0, \cdots)$. Consider the sequence $(x_1, x_2, \cdots)=(1, 0, 1, 0, 1, 0, \cdots)$. Then $f(x_3, x_4, \cdots)=f(1, 0, 1, 0, \cdots)=2\neq x_2$, and $f(x_5, x_6, \cdots)=f(1, 0, 1, 0, \cdots)=2\neq x_4$, etc. Clearly $f(x_{n+1}, x_{n+2}, \cdots)$ fails to equal x_n for infinitely many values of n.

Dr. Silverman has, accordingly, withdrawn his submission with apologies. We offer instead:

II. *Solution by B. L. D. Thorp, York University, Toronto.* This problem can be generalized as follows: Let S denote the set of all real sequences $x=(x_1, x_2, \cdots)$ and let ϕ be a strictly increasing mapping of the positive integers N into itself. If the mapping T on S is defined by

$$Tx = (x_{\phi(1)}, x_{\phi(2)}, x_{\phi(3)}, \cdots),$$

characterize those functions ϕ for which there exists a function f on S satisfying

$$x_n = f(T^n x) \quad (x \in S)$$

for all but finitely many n.

It is shown that f exists if and only if the complement of $\phi(N)$ in N consists of exactly one point. Suppose that $N\backslash\phi(N)$ is empty. Then T is the identity mapping and no f exists. If $N\backslash\phi(N)$ is infinite, the sequence

$$x_i = \begin{cases} 0 & i \in \phi(N) \\ 1 & i \notin \phi(N) \end{cases}$$

fails to satisfy the condition for any function f. Suppose that $N\backslash\phi(N)$ consists of the points $k_1<k_2<\cdots<k_p$, where $p>1$. The sequence

$$x_i = \begin{cases} 1 & \text{for } i \geqq k_p \text{ and } i - k_p \equiv 0 \pmod{p} \\ 0 & \text{otherwise} \end{cases}$$

fails to satisfy the condition for any function f on S. The necessity of the condition is established.

Suppose that $\{k\} = N \backslash \phi(N)$. Define an equivalence relation on S by writing $x \sim y$ if there exist $p, q \in N$ such that $T^p x = T^q y$. Clearly $x \sim y$ if and only if there exist positive integers p, q such that $x_{p+i} = x_{q+i}$ for $i \geqq k$ and $x_i = y_t$ for $1 \leqq t \leqq k-1$. Suppose that the equivalence class A contains an element which is eventually periodic. An element x in A can be chosen and $r \geqq k$ determined such that $x_i = x_{i+r}$ for $i \geqq k$. Define f on A by

$$f(y) = \begin{cases} x_{r+n} & \text{if } y = T^n x \quad (n = 0, 1, 2, \cdots) \\ 0 & \text{otherwise.} \end{cases}$$

f is well-defined on A and satisfies the required condition. If B is an equivalence class which does not contain an element which is eventually periodic, choose an element x of B and define f on B by

$$f(y) = \begin{cases} 0 & \text{if } y = x \\ x_n & \text{if } y = T^n x \quad (n = 1, 2, \cdots) \\ 0 & \text{otherwise.} \end{cases}$$

Sums and Composition of Legendre Symbols

5388 [1966, 421]. *Proposed by L. Carlitz, Duke University*

Let p be an odd prime and put

$$K(a, b) = \sum_{x=1}^{p-1} e(ax + bx') \qquad (e(x) = e^{2\pi x i/p}), \quad xx' \equiv 1 \pmod{p},$$

$$J(a) = \sum_{x=1}^{p-1} \psi(x)\psi(x^2 - a),$$

where $\psi(x) = (x/p)$, the Legendre symbol. Show that, for $p \equiv 1 \pmod 4$,

$$\sum_{a=1}^{p-1} K(a, b)J(4a) = \begin{cases} 0 & (\psi(b) = -1) \\ 2pG(c) & (b = c^2, \quad c \neq 0), \end{cases}$$

where $G(c) = \sum_{x=1}^{p-1} \psi(x)e(cx)$.

I. *Solution by R. A. Smith, University of Toronto.* We prove the following more general result: Let p be an odd prime and let $\psi(x) = (x/p)$, the Legendre symbol. For any integer z co-prime to p, define z' by $zz' \equiv 1 \pmod p$. Put

$$K(a, b) = \sum_{x=1}^{p-1} e(ax + bx'), \qquad (b, p) = 1,$$

(since $\psi(-1)=1$). We have therefore, for $b=c^2$, $c\neq 0$,

$$\sum_{a=1}^{p-1} K(a, b)J(a) = 2pG(c).$$

Also solved by M. G. Greening (Australia), and K. S. Williams.

Nonisomorphic Ordered Fields

5400 [1966, 673]. *Proposed by W. C. Waterhouse, Harvard University*

Find, or disprove the existence of, two (totally) ordered fields which are isomorphic as fields and isomorphic as ordered sets, but not isomorphic as ordered fields.

Solution by G. A. Heuer, University of California at Berkeley. We exhibit three ordered fields, two of which are Archimedean ordered and the third non-Archimedean ordered, all three of which are isomorphic as fields, all three isomorphic as ordered sets, and no two of which are isomorphic as ordered fields.

Let Q be the field of rationals, and $F_1=Q(\alpha)$, $F_2=Q(\beta)$, and $F_3=Q(t)$, where t is an indeterminate. (α and β are algebraically independent transcendentals over the rationals.) F_1 and F_2 are ordered as subfields of the ordered field R of real numbers. In F_3 a polynomial is positive if and only if its leading coefficient is positive, and a quotient of polynomials is positive iff numerator and denominator are both positive or both negative. F_3 is a well-known example of a non-Archimedean ordered field; F_1 and F_2, as subfields of R, are Archimedean. That all three are isomorphic fields is familiar; that all are isomorphic as ordered sets follows from the fact that any two denumerably infinite dense ordered sets without first or last elements are order isomorphic. That F_3 is not isomorphic to F_1 or F_2 as ordered fields is already clear; that F_1 and F_2 are not isomorphic ordered fields is seen as follows. The only field isomorphisms of F_1 and F_2 are those generated by $\alpha\to a\beta+b$, where a and b are rational. Let $\beta'=a\beta+b$, and let m and n be integers such that m/n lies between α and β', and $n>0$. Then $m-n\alpha$ and $m-n\beta'$ lie on opposite sides of 0, so no field isomorphism of F_1 onto F_2 maps positives to positives.

Various generalizations to larger sets of such fields are more or less immediately noticed. In particular, one may have an infinite sequence $\{K_0, K_1, \cdots\}$ of such fields, with each $K_i\subset K_{i+1}$ and K_{i+1} non-Archimedean over K_i (i.e., possessing infinitely large elements over K_i). Let $\{a_1, a_2, \cdots\}$ be an algebraically independent, denumerably infinite set of transcendental real numbers, and $\{t_1, t_2, \cdots\}$ a denumerably infinite set of indeterminates. The fields $K_0=Q(a_1, a_2, \cdots)$, $K_n=K_{n-1}(t_n)$ for $n=1, 2, \cdots$, where the order in K_0 is induced by that in R, and K_n gets its order from K_{n-1} as F_3 did from Q, are all isomorphic as fields and as ordered sets, but no two are isomorphic as ordered fields.

Matrices of Rank 2

5401 [1966, 674]. *Proposed by Charles Wells, Duke University*

Let ϵ be a primitive nth root of unity. Define a matrix $A=(a_{ij})$ by $a_{rs}=\epsilon^r-\epsilon^s$ for $r, s=1, 2, \cdots, n$. Find the rank of A.

Solution by Dennis A. Hejhal, Student, University of Chicago. For $n\geqq 2$, the rank of A is 2. More generally, this is also true of $a_{rs}=x_r-y_s$ if $\{x_r\}$, $\{y_s\}$ are nonconstant. To see this, note that if the first column is subtracted from the kth column, the result is the constant column y_1-y_k; this implies that the rank of A cannot exceed 2. The identity

$$\begin{vmatrix} x_j - y_t & x_j - y_u \\ x_k - y_t & x_k - y_u \end{vmatrix} = (x_j - x_k)(y_t - y_u)$$

and the nonconstancy of $\{x_r\}$, $\{y_s\}$ now imply that the rank of A is precisely 2.

Gibson & J. A. Marlin, Eldon Hansen, W. E. Hoff, Thomas Jefferson, Jr.,GeoffreyKandall, Daniel Marcus, J. G. Mauldon (England), M. D. Mavinkurve (India), Ka Menehune, Norman Miller, J. P. Muskat, Dave Nixon, Vishnu Parkash (India), Alfred Pietrowski, J. R. Purdy, Sister Marion Beiter & Robert DeCarli, Sidney Spital, J. E. Wilkens, Jr., and the proposer.

A Pair of Oscillatory Functions

5402 [1966, 674]. *Proposed by David Shelupsky, The City College, New York*

For $N>-1$ let the functions f and g be defined by the expansions

$$f(x) = \sum_{m=0}^{\infty} (-1)^m \frac{x^{2m+N+1}}{(2m+N+1)!(2m+1)!},$$

$$g(x) = \sum_{m=0}^{\infty} (-1)^m \frac{x^{2m+N}}{(2m+N)!(2m)!},$$

which somewhat resemble the expansions of the trigonometric functions. Prove that each of these functions has, in common with the trigonometric functions, an infinite number of real zeros.

I. *Solution by H. C. Howard, University of Wisconsin at Milwaukee.* A simple calculation yields the following equations for $f(x)$, $g(x)$:

$$xf''(x) - (N-1)f'(x) = g(x)$$
$$xg''(x) - (N-1)g'(x) = -f(x).$$

From these it follows that both $f(x)$ and $g(x)$ are solutions of

$$[x^{-N-2}y''(x)]'' + x^{-N}y(x) = 0.$$

Thus f and g are solutions of an ordinary differential equation of the form $(r(x)y''(x))''+p(x)y(x)=0$, with $r(x)$ and $p(x)$ positive as $x\to\infty$. Oscillatory properties of solutions of such equations have been studied by Leighton and Nehari in their paper, *On the oscillatory solutions of self-adjoint linear differential equations of the fourth order*, Trans. A. M. S., v. 89 (2), (1958) 325–377. The solution of the present problem is contained in

THEOREM 11.1: *If there exists a real number* α *such that* $\limsup_{x\to\infty}x^{-2-\alpha}r(x)<1$, *and* $\liminf_{x\to\infty}4x^{2-\alpha}p(x)>\alpha^2$, *then every nontrivial solution of the equation* $(ry'')''+py=0$ *possesses an infinite number of distinct real zeros.*

Thus, choosing $\alpha=-(N-1)$ for example, and noting $\limsup_{x\to\infty}x^{-2+N-1}x^{-N+2}=0$, and $\liminf_{x\to\infty}4x^{2+N-1}x^{-N}=\infty$, an application of this theorem yields the desired result.

II. *Solution by L. E. Ward, Sr., Escondido, Cal.* The identity

$$e^{-N\pi i/4}x^{N/2}J_N(2\sqrt{ix}) = g(x) - if(x)$$

yields, for large positive x, the asymptotic relations

$$f(x) \sim p(x)\cdot\sin(\sqrt{2x} - N\pi/4 - \pi/8),$$
$$g(x) \sim p(x)\cdot\cos(\sqrt{2x} - N\pi/4 - \pi/8),$$

where $p(x)=e^{\sqrt{2x}}x^{N/2-1/4}/2\sqrt{\pi}$. The result of the problem follows from these relations. It is to be noted that the restriction $N>-1$ is not needed. The functions f, g are closely related to Thompson's functions; see, e.g., Watson, *Bessel Functions*, rev. ed., section 3.8.

III. *Solution by A. Jakimovski, University of Tel-Aviv, Israel.* We shall prove that $f(x)$ and $g(x)$ have an infinite number of zeros and that all the zeros are real. The functions $z^{-N-1}f(z)$ and $z^{-N}g(z)$ are entire functions of order $1/2$. Therefore they have an infinite number of real or complex zeros. (See Titchmarsch, *The Theory of Functions* (Oxford, 1939), Section 8.26, p. 252.) By applying the theorem of Section 8.62 in Titchmarsch (which is true for $a\geqq 0$) to the pair of functions

$$f_1(z) = \sum_{n=0}^{\infty}\frac{z^n}{(2n)!} = \cos i\sqrt{z} = \prod_{n=0}^{\infty}\left(1+\frac{z}{(n-1/2)^2\pi^2}\right),$$

$$\phi_1(z) = \frac{1}{\Gamma(2z+N+1)}, \quad (N>-1),$$

it follows that all the zeros of the function

$$\sum_{n=0}^{\infty} \frac{z^n}{(2n+N)!(2n)!}$$

are real and negative. Hence all the zeros of $g(z)$ are real. Similarly, by applying the same theorem to the pair of functions

$$f_2(z) = \sum_{m=0}^{\infty} \frac{z^m}{(2m+1)!} = \frac{\sin i\sqrt{z}}{i\sqrt{z}} = \prod_{n=0}^{\infty}\left(1 + \frac{z}{\pi^2 n^2}\right),$$

$$g_2(z) = \frac{1}{\Gamma(2z+N+2)}, \quad (N > -2),$$

it follows that all the zeros of $f(z)$ are real.

IV. *Solution by F. W. Steutel, Technische Hogeschool Twente, Netherlands.* The Laplace transforms ϕ and γ of f and g (restricted to $x \geqq 0$) are

$$\phi(\tau) = \tau^{-N-1} \sin\frac{1}{\tau}, \qquad \gamma(\tau) = \tau^{-N-1} \cos\frac{1}{\tau}.$$

If $f(x)$ has no zeros on (x_0, ∞) then in

$$\phi(\tau) = \int_0^{x_0} e^{-\tau x} f(x)\,dx + \int_{x_0}^{\infty} e^{-\tau x} f(x)\,dx$$

the first integral remains bounded if $\tau \downarrow 0$ while the second is monotone. It would follow that $\phi(\tau)$ either has a limit (finite or infinite) for $\tau \downarrow 0$ or remains bounded. As this clearly contradicts the facts, $f(x)$ (and in the same way, $g(x)$) has zeros exceeding x_0 for every x_0. Therefore $f(x)$ and $g(x)$ have infinitely many zeros.

Also solved by M. D. Mavinkurve (India), J. J. Roseman, and the proposer.

Primitive Simple Rings

5403 [1966, 674]. *Proposed by Kwangil Koh, North Carolina State University*

It is known that a simple ring is not necessarily primitive. Prove that if R is a simple ring such that for each right (or left) ideal I of R, $IR = I (RI = I)$, then R is primitive.

Solution by Ram N. Gupta, Ramjas College, Delhi, India. It is sufficient to show that R has a maximal right ideal. Let $x \neq 0$ be in R. Let $\bar{x}$ be the right ideal of R generated by x. Then $\bar{x}R = \bar{x}$, so $xR = \bar{x}$. $xe = x$ for some $e \in R$. $ey - y \in x^r$ for every $y \in R$ and $e \notin x^r$. Use Zorn's lemma to show that there exists a maximal member J of the family $\{I: I$ right ideal of R, $e \notin I$, $I \supseteq x^r\}$. J will in fact be a maximal right ideal of R.

REMARK. The above argument can be used to prove that a simple ring for which there exists M, a strictly cyclic ($xR = M$ for some $x \neq 0$ in M) right R module, is primitive.

Also solved by R. A. Howland, and by the proposer.

Almost-Pythagorean Triples

5404 [1966, 674]. *Proposed by George Grossman, Board of Education, New York City*

By an almost-Pythagorean triangle we mean one whose sides are natural numbers satisfying $a^2+b^2=c^2\pm 1$. Derive formulas for determining a, b, c. In particular, show that if (a_1, b_1, c_1) is a solution, then there are infinitely many solutions (a, b, c) with $a/c=a_1/c_1$ and infinitely many with $a/b=a_1/b_1$.

I. *Solution by Charles Wexler, Arizona State University.* Given

$$a^2 \pm 1 = (c + b)(c - b), \tag{1}$$

we assume there are integral solutions, and put $r=c+b$, $s=c-b$, so that $c=\frac{1}{2}(r+s)$, $b=\frac{1}{2}(r-s)$. We note that

$$rs = a^2 \pm 1, \qquad r \geqq s, \qquad r \equiv s \pmod 2. \tag{2}$$

Conversely, if r, s satisfy (2) for some choice of a, then $b=\frac{1}{2}(r-s)$, $c=\frac{1}{2}(r+s)$ are integers satisfying (1). Now, in case $a^2-1=rs$, we see that for every $a\geqq 2$ there always exist natural numbers r, s, given by (2) (excluding the trivial case $a+1=r=s+2$), which produce satisfactory values of b, c. In case $a^2+1=rs$, $r\equiv s \pmod 2$ implies a is even. Hence for every even a there exist r, s, and, hence, b, c.

If (a_1, b_1, c_1) is a solution, we seek integers k, b such that (ka_1, b, kc_1) is a solution of (1). Substitution in (1) gives $k^2a_1^2-1=k^2c_1^2-b^2$ or $b^2-k^2(b_1^2-1)=1$. This is a Pell equation of the form $x^2-Dy^2=1$, where $D=b_1^2-1$ is nonsquare, which is known to have infinitely many solutions in integers b, k.

If we wish solutions (a, b, c) with $k=a/a_1=b/b_1$, we obtain similarly $c^2-(c_1^2+1)k^2=-1$. Again c_1^2+1 is nonsquare. This type of Pell equation does not always have solutions, but when it has one solution, as in our case, it also has infinitely many, as required.

II. *Solution by Michael Goldberg, Washington, D. C.* A solution for $a^2+b^2=c^2+1$ is obtained as a special case of the equation $a^2+b^2=c^2+d^2$, for which the general solution is given in L. E. Dickson, *History of the Theory of Numbers*, v. 2, p. 254. It is

$$2a = uv + xy, \qquad 2b = ux - vy, \qquad 2c = ux + vy, \qquad 2d = uv - xy.$$

If we choose arbitrary sets u, v, x, y subject to the condition that $2d=uv-xy=2$, then all solutions of the special case may be obtained.

Solutions for $a^2+b^2=c^2-1$ are obtained as a special case of the equation $a^2+b^2+d^2=c^2$. The general solution of this equation is given (loc. cit. p. 269). It is

$$a = 2(ux + vy), \qquad b = 2(uy - vx), \qquad c = u^2 + v^2 + x^2 + y^2,$$

$$d = u^2 + v^2 - x^2 - y^2.$$

If we choose arbitrary sets u, v, x, y subject to the condition

$$d = (u + x)(u - x) - (y + v)(y - v) = 1,$$

then all the solutions of the special case may be obtained.

Since, in both cases there are four variables connected by the relation $d=1$, the imposition of the condition $a/c=k$, or $a/b=k$, still leaves two variables in a Diophantine equation, and this permits an infinity of solutions.

Also solved by V. S. Ananthachar (India), Walter Bluger, Julia Caspino, M. A. Ettrick, M. G. Greening (Australia), K. E. Hirst (England), Norman Miller, C. Stanley Ogilvy, Vishnu Parkash (India), and A. Thyagaraja (India).

Editorial Note. Thyagaraja, in his solution, shows that $(2mn+1, mn^2-m+n, mn^2+m+n)$ is a solution of $a^2+b^2=c^2+1$.

Bluger shows that if (a, b, c) is a solution of $a^2+b^2=c^2-1$, then so is $(2ac, 2bc, 2c^2-1)$, establishing infinitely many solutions with constant ratio a/b. Likewise if (a, b, c) is a solution of $a^2+b^2=c^2+1$, then so is $(2ab, 2b^2-1, 2bc)$.

Ogilvy referred to another recent appearance of the problem. See *The New York State Mathematics Teachers Journal*, 16 (1966) 19.

Solution I above meets the stated requirements of the problem but is not quite satisfactory as a complete solution of (1). Factorization of $a^2\pm1$ is required, and it may be entirely impossible to find all possible values of r and s when a is large. In solution II where we must solve $uv-xy=2$, we can start with arbitrary values of u and x, with $(u, x)|2$, and solve the resulting linear Diophantine equation for v, y, of which there are infinitely many sets. A similar comment applies to the condition on d in the second case.

Normal Subgroups in a Finite Group of Even Order

5406 [1966, 674]. *Proposed by C. C. Lindner, Coker College, Hartsville, S. C.*

Prove that a finite group of order $2n$ which contains an element of order n has at least $\tau(n)+1$ normal subgroups. $\tau(n)$ is the number of divisors of n.

Solution by Gomer Thomas, University of Illinois. Let G have order $2n$, let x be an element in G of order n, and let $\langle x\rangle$ be the cyclic group generated by x. Then $|G:\langle x\rangle| = 2$, so $\langle x\rangle$ is normal in G. For every integer m dividing n there is exactly one subgroup of $\langle x\rangle$ of order m, namely the subgroup generated by $x^{n/m}$. Thus $\langle x\rangle$ has exactly $\tau(n)$ subgroups, each of which is characteristic in $\langle x\rangle$ and hence normal in G, so the number of normal subgroups of G (including G itself) is at least $\tau(n)+1$.

Also solved by W. O. Alltop, J. L. Berggren, J. L. Brenner, P. R. Chernoff, Eleanor G. Dawley, J. F. Dillon, Annabel Fong, N. Ganesan (India), Kenneth Gehner, H. A. Gindler, Myron Goldberg & Gautam Pandya, Agatha Himmelfarb, E. C. Hook, Erwin Just, R. S. Kaluzniacki, Geoffrey Kandall, Betty Kvarda, Arthur Lieberman, A. F. Long, Jr., M. D. Mavinkurve (India), Jagan M. Mital (India), Wanda J. Mourat, Vishnu Parkash (India), Donald Quiring, W. R. Scott, K. N. Sigmon, C. H. Toll, Qazi Zameeruddin (India), and the proposer.

Note. As observed by several solvers, the critical aspect of this problem is contained in I. N. Herstein, *Topics in Algebra*, p. 45, ex. 13.

A Nondecreasing Indicator Function

5407 [1966, 674]. *Proposed by S. W. Golomb, University of Southern California*

Let $f(n)$ be a function with both range and domain the positive integers, and define $g(n)$ to be the number of values of m such that $f(m)=n$. If $f(n)$ is monotone nondecreasing and satisfies $f(n)=g(n)$ for all n, then $f(n)$ is uniquely determined. Find an asymptotic expression for $f(n)$ as $n\to\infty$.

I. *Solution by Daniel Marcus, Student, Adelphi University.* First notice that the sequence defined by $a_n=f(n)$ is 1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, 6, 6, 6, 6, $\cdots$. It follows from the properties of f that the kth block of consecutive equal entries (all equal to k) has length a_k. Now suppose that h is a continuous, differentiable function defined for all positive x, such that h agrees with f at the terminal point of each block, that is, $h(n)=f(n)$ for n satisfying $n=\sum_{k=1}^{f(n)}f(k)$. Then by the mean value theorem, there must exist, for each n, ξ_n in the open interval $(\sum_{k=1}^{f(n)-1}f(k),\ \sum_{k=1}^{f(n)}f(k))$ such that $h'(\xi_n)=1/f(f(n))$. Allowing $h'(\xi_n)\approx h'(n)$, this leads us to suspect that an asymptote F of f satisfies the differential equation $F'(x)=1/F(F(x))$. One solution is easily obtainable. Setting $F(x)=ax^r$, we find that $a=(\phi-1)^{-1/(\phi+1)}$ and $r=\phi-1$, where $\phi=\frac{1}{2}(1+\sqrt{5})$. Therefore as $n\to\infty$, $f(n)$ is approximated by $((\sqrt{5}+1)/2)^{(3-\sqrt{5})/2}n^{(\sqrt{5}-1)/2}$.

II. *Solution by N. J. Fine, Pennsylvania State University.* We shall prove that $f(n)\sim\delta^{\delta-1}n^{\delta}$, where $\delta=(\sqrt{5}-1)/2$.

Let $k(0)=0$ and for $M\geqq 1$, let $k(M)$ be the greatest j for which $f(j)=M$. Thus

$$k(M-1)<n\leqq k(M)\Leftrightarrow f(n)=M\quad(M\geqq 1). \tag{1}$$

Since the number of n's for which (1) holds is $f(M)$, we have

$$f(M)=k(M)-k(M-1)\quad(M\geqq 1). \tag{2}$$

Therefore

$$k(M)=\sum_{n=1}^{M}f(n). \tag{3}$$

We need some preliminary estimates. Since $f(n)\geqq 1$, we have $k(M)\geqq M$, so $M=f(k(M))\geqq f(M)$. By (3),

$$k(M)\leqq\sum_{n=1}^{M}n=\frac{M^2+M}{2}\leqq M^2.$$

Hence, for all $n\geqq 1$, by (1), $n\leqq k(f(n))\leqq f^2(n)$. That is

$$f(n)\geqq\sqrt{n}\quad(n\geqq 1). \tag{4}$$

From (3) again,

$$k(M)\geqq\sum_{n=1}^{M}\sqrt{n}\geqq\int_0^M x^{1/2}dx=\tfrac{2}{3}M^{3/2}\quad(M\geqq 1). \tag{5}$$

Now suppose that N is an integer >1 and that A and B are positive numbers such that

$$Aj^{\delta} \leqq f(j) \leqq Bj^{\delta} \quad (j \leqq N). \tag{6}$$

Then, for all $M \leqq N$,

$$k(M) = \sum_{j=1}^{M} f(j) \leqq B \sum_{j=1}^{M} j^{\delta} \leqq B \int^{M+1} x^{\delta} dx = \frac{B}{1+\delta} (M+1)^{1+\delta}$$

and

$$k(M) \geqq A \sum_{j=1}^{M} j^{\delta} \geqq A \int_{0}^{M} x^{\delta} dx = \frac{A}{1+\delta} M^{1+\delta}.$$

Using the fact that $1+\delta = 1/\delta$, we have

$$A\delta M^{1/\delta} \leqq k(M) \leqq B\delta(M+1)^{1/\delta} \quad (M \leqq N). \tag{7}$$

If $n \leqq k(N)$, then $f(n) \leqq N$, so we can put $M = f(n)$ and $M = f(n)-1$ in (7) to get $k(f(n)) \leqq B\delta(f(n)+1)^{1/\delta}$, $k(f(n)-1) \geqq A\delta(f(n)-1)^{1/\delta}$. By (1), $k(f(n)-1) < n \leqq k(f(n))$, so

$$A\delta(f(n)-1)^{1/\delta} < n \leqq B\delta(f(n)+1)^{1/\delta}, \quad (n \leqq k(N)). \tag{8}$$

Now if $n > N$, we have by (4), $1/f(n) \leqq 1/f(N) \leqq 1/\sqrt{N}$, and

$$f(n) + 1 = f(n)\left(1 + \frac{1}{f(n)}\right) \leqq f(n)\left(1 + \frac{1}{\sqrt{N}}\right),$$

$$f(n) - 1 = f(n)\left(1 - \frac{1}{f(n)}\right) \geqq f(n)\left(1 - \frac{1}{\sqrt{N}}\right).$$

Hence, from (8),

$$A\delta\left(1 - \frac{1}{\sqrt{N}}\right)^{1/\delta} f(n)^{1/\delta} < n \leqq B\delta\left(1 + \frac{1}{\sqrt{N}}\right)^{1/\delta} f(n)^{1/\delta}, \quad (N < n \leqq k(N)).$$

Therefore

$$(B\delta)^{-\delta}\left(1 + \frac{1}{\sqrt{N}}\right)^{-1} n^{\delta} \leqq f(n) \leqq (A\delta)^{-\delta}\left(1 - \frac{1}{\sqrt{N}}\right)^{-1} n^{\delta}, \quad (N < n \leqq k(N)).$$

Since $(1+1/\sqrt{N})^{-1} > (1-1/\sqrt{N})$, we have

$$(B\delta)^{-\delta}\left(1 - \frac{1}{\sqrt{N}}\right) n^{\delta} \leqq f(n) \leqq (A\delta)^{-\delta}\left(1 - \frac{1}{\sqrt{N}}\right)^{-1} n^{\delta}, \quad (N < n \leqq k(N)).$$

For $x > 0$, define $\psi(x) = cx^{-\delta}$, where $c = \delta^{-\delta}$. Also write $\lambda(N) = 1 - 1/\sqrt{N}$. Then

$$\psi(B)\lambda(N)n^{\delta} \leqq f(n) \leqq \psi(A)\lambda^{-1}(N)n^{\delta} \quad (N < n \leqq k(N)). \tag{9}$$

Let us say that (A, B) is a *stable pair* if

$$0 < A \leqq \psi(B), \qquad \psi(A) \leqq B. \tag{10}$$

If (A, B) in (6) is a stable pair, then from (9) and (10),

$$A\lambda(N)n^{\delta} \leqq f(n) \leqq B\lambda^{-1}(N)n^{\delta} \quad (N < n \leqq k(N)). \tag{11}$$

Since $\lambda(N) < 1$, $\lambda^{-1}(N) > 1$, so from (6) and (11),

$$A'n^{\delta} \leqq f(n) \leqq B'n^{\delta} \quad (n \leqq k(N)), \tag{12}$$

where

$$A' = A\lambda(N), \qquad B' = B\lambda^{-1}(N). \tag{13}$$

Now, observe that if (A, B) is a stable pair and if $0 < \lambda \leqq 1$, then $(\lambda A, \lambda^{-1}B)$ is also a stable pair. For

$$\psi(\lambda^{-1}B) = \lambda^{\delta}\psi(B) \geqq \lambda\psi(B) \geqq \lambda A > 0,$$
$$\psi(\lambda A) = \lambda^{-\delta}\psi(A) \leqq \lambda^{-1}\psi(A) \leqq \lambda^{-1}B.$$

Thus we have the basis for an induction. If we define $N_0 = N$, $N_{r+1} = k(N_r)$, $(r \geqq 0)$, and $\lambda_{r+1} = \lambda(N_r)$, $(r \geqq 0)$, the hypothesis that (A, B) is a stable pair and that (6) holds leads to

$$A\lambda_1\lambda_2 \cdots \lambda_r n^{\delta} \leqq f(n) \leqq B(\lambda_1\lambda_2 \cdots \lambda_r)^{-1}n^{\delta}, \quad (n \leqq N_r) \tag{14}$$

for every $r \geqq 1$.

To begin the induction, we take $N_0 = 2$, $A = 1$, $B = \delta^{-1}$. It is easily verified that (6) holds and that (A, B) is a stable pair, so (14) holds. Now we use (5) to get a lower bound for N_r. For $M \geqq 3$, $\frac{2}{3}M^{3/2} > M^{1.1}$. Since $N_1 = k(2) = 3$, we have $N_2 > 3^{1.1}$, $N_3 > 3^{(1.1)^2}$, and for all $r \geqq 1$,

$$N_r > 3^{(1.1)^{r-1}}.$$

Hence in (14) the products $\lambda_1\lambda_2 \cdots \lambda_r$ are bounded away from 0, and there are positive constants A_0, B_0 such that

$$A_0 n^{\delta} \leqq f(n) \leqq B_0 n^{\delta} \quad (n \geqq 1). \tag{15}$$

Thus, if we define

$$\alpha = \liminf f(n)n^{-\delta}, \qquad \beta = \limsup f(n)n^{-\delta},$$

we have $0 < \alpha \leqq \beta < \infty$. It remains to show that $\alpha = \beta$ and to evaluate this constant. Now

$$\limsup N^{-1/\delta}k(N) = \limsup \frac{1}{N^{1+\delta}} \sum_{j=1}^{N} f(j) \leqq \frac{1}{1+\delta} \limsup f(j)j^{-\delta} = \beta\delta.$$

Since $n \leqq k(f(n))$,

$$\limsup f(n)^{-1/\delta}n \leqq \beta\delta, \qquad \limsup f(n)^{-1}n^{\delta} \leqq (\beta\delta)^{\delta},$$

so

$$\alpha^{-1} = (\liminf f(n)n^{-\delta})^{-1} \leqq (\beta\delta)^{\delta},$$

that is,

$$\alpha\beta^{\delta} \geqq \delta^{-\delta}. \tag{16}$$

Similarly, we find $\liminf N^{-1/\delta}k(N) \geqq \alpha\delta$. Since $n > k(f(n)-1)$,

$$\liminf (f(n) - 1)^{-1/\delta}n \geqq \alpha\delta.$$

Therefore $\beta^{-1} = (\limsup (f(n)-1)n^{-\delta})^{-1} = \liminf (f(n)-1)^{-1}n^{\delta} \geqq (\alpha\delta)^{\delta}$, that is,

$$\delta^{-\delta} \geqq \beta\alpha^{\delta}. \tag{17}$$

From (16) and (17) we see that

$$\left(\frac{\alpha}{\beta}\right)^{1-\delta} = \frac{\alpha\beta^{\delta}}{\beta\alpha^{\delta}} \geqq 1,$$

so $\alpha \geqq \beta$. Since $\alpha \leqq \beta$, equality holds. Putting $\beta = \alpha$ in (16) and (17), we get $\alpha^{1/\delta} = \alpha^{1+\delta} = \delta^{-\delta}$, so $\alpha = \delta^{-\delta^2} = \delta^{\delta-1}$. Hence finally, as promised,

$$\lim_{n\to\infty} f(n)n^{-\delta} = \alpha.$$

Also solved by J. H. van Lint, and by the proposer.

Collections of Sets of Positive Measure

5408 [1966, 674]. *Proposed by Thaddeus Dankel, Princeton University*

Let C be any infinite collection of distinct Lebesgue-measurable subsets of $[0, 1]$ each having measure $\geqq \epsilon$, where ϵ is a fixed positive number <1. Show that there exists an infinite subcollection $C_0 \subset C$ of distinct sets E such that $m(\bigcap_{E\in C_0} E) > 0$.

I. *Solution by P. R. Chernoff and W. C. Waterhouse, Harvard University.* The stated result is false no matter how close ϵ is to 1. Indeed, let S_n be the set of numbers in $(0, 1)$ whose nth digit in the b-ary expansion is not 0. The intersection of any k of these has measure $((b-1)/b)^k$. Hence the intersection of any infinite subcollection has measure zero.

On the other hand, if 1 is an accumulation point of $\{m(E) : E \in C\}$ there is an infinite subset $C_0 \subset C$ such that $\sum_{E\in C_0}(1-m(E)) < 1$. Hence $m(\bigcap_{E\in C_0} E) > 0$.

II. *Comment by J. Gillis, The Weizmann Institute of Science, Israel.* If C is nondenumerable then the result is true. Indeed it is then known that for any $\eta > 0$ we can find an infinite subcollection of C whose intersection has measure

$>\epsilon-\eta$ [cf. J. Gillis, Quart. J. Math., 7 (1936) 191–198]. Without this additional condition it has been shown that for any $\eta>0$ and natural number r we can always find r distinct sets E whose intersection has measure $>\epsilon^r-\eta$ and that this result is best possible [cf. J. Gillis, J. London Math. Soc., 11(1936)139–141].

Also solved by T. V. Fossum, Frank Gilfeather, A. Jakimovski (Israel), J. G. Mauldon (England), David Preiss (Czechoslovakia), W. R. Scott, Yam-Tung Siu, and L. J. Wallen.

Fossum shows that there exists an infinite subcollection C_0 such that $\cap_{E\in C_0} E$ is nonempty, under the hypothesis of the problem as stated.

Subrings of Direct Sums of Copies of I_k

5409 [1966, 675]. *Proposed by R. A. Melter, University of Massachusetts*

Let k be a square-free positive integer greater than 1 and let R be a subring of the complete direct sum of an arbitrary number of copies of I_k, the ring of integers modulo k. Show that R is the direct sum of a finite number of p-rings. (A p-ring is a ring in which the identities $px=0$ and $x^p=x$ are satisfied for all x and for some positive prime p.)

Solution by G. A. Heuer, University of California at Berkeley. Let $k=p_1\ p_2 \cdots p_r$, where the p_i are distinct and prime. Let P_i be the subring of I_k generated by k/p_i. P_i is isomorphic to the field I_{p_i}, which is clearly a p_i-ring. Moreover, it is readily seen that I_k is the internal direct sum of the P_i.

Let S be the complete direct sum of a family of copies of I_k (indexed by A, say). If S_i is the complete direct sum of a family of copies of P_i indexed by A, then each S_i is a p_i-ring, and S is isomorphic to $S_1\oplus \cdots \oplus S_r$. R is a subring of S; if we identify S with $S_1\oplus \cdots \oplus S_r$, and put $R_i=R\cap S_i$, we have $R=R_1\oplus \cdots \oplus R_r$, where each R_i, being a subring of a p-ring, is a p-ring.

Also solved by N. J. Fine, Wanda J. Mourant, and the proposer.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto, 5, Canada. Correspondence about reviews is welcomed.

Algèbre linéaire et géométrie élémentaire. By Jean Dieudonné. Hermann, Paris, 1964. 233 pp. 36 F.

It would be an exciting experiment to have a couple of living mathematicians each write a book on elementary linear algebra. I guess that it would not be difficult to find criteria to compare the results systematically. The most striking feature and perhaps a means to arrange them in a linear order would probably be the amount of regard or disregard of the author for the reader. There are textbook writers who believe that a mathematical exposition without logical gaps explains itself to the presumed reader who faith-

fully follows the author step by step, and that the secret about what the whole thing means need not to be told by the author explicitly, but has to be grasped by the reader from the details he has swallowed. There are other guides who prefer to take the guided ones into confidence, to tell them where the road goes and why this one is better than another. The main stream textbook writer sails between Scylla and Charybdis. As a mathematician he is possessed by systematism, and as a teacher he is plagued by didactic scruples. Indeed, systematism is a nondidactical attitude which often turns antididactical. A common way out is to give rein to one's passion for systematism in the main part and to give full credit to didactic goals in the problems set after every chapter. This way out is as old as Euclid, who during centuries puzzled his readers by the seemingly crazy, because unmotivated, arrangement of his theorems and proofs, while, on the other hand, he used to introduce his so-called constructions by motivations called analysis.This Euclidean spirit still prevails in many textbooks, and so it does in Dieudonné's.

The inventor of the slogan "A bas Euclide" a follower of Euclid? It looks odd, but it does so simply because few slogans have been misunderstood as badly as this one. Partly, it was Dieudonné's own fault. When he cried "A bas Euclide," he actually meant "A bas 'Euclide'," (viz. the Euclid of French lycée textbooks), but in oral discussions it is a hard thing to pronounce quotation marks.

To come back to our experimental couple of textbook writers, one can easily imagine many respects in which their productions would diverge from each other, from the dreary examples of French typography to some highlights of international snobism. As a typographical product Dieudonné's book, though still difficult to read, is much superior to the average French production. As to the content proper and its arrangement the couple of authors would not probably disagree very much. Their interpretations of what elementary linear algebra means, would be as identical as they can be. So there is some reason to ask why Dieudonné wrote a book which could have been written by many other people. Of course Dieudonné performed much better than other people would have done, but probably not so much better that it would justify his preoccupation with this subject.

Dieudonné has tried to answer this question in the preface, which faithfully reflects Dieudonné's sympathetic image as a forceful defender of all possible inconsistencies. According to the second paragraph of the preface this book is a teacher's textbook, and to prove this pretention, he hammers at the educational merits of its subject matter and the educational flaws of any other one, only to finish with the anticlimatical last paragraph where suddenly he declares that he has no personal interest in problems of secondary education. "I simply wished to add to the files of the future historian an example of what one could do in this matter if one would try to act in a rational way." I do not understand this emphatic utterance, and I doubt whether anybody, Dieudonné included, can explain it. Does it mean that the teacher's textbook being written, Dieudonné retires into an ivory tower to have teachers who do not agree to accept it as their textbook, judged by history?

However, it is by no means clear in which sense Dieudonné has meant this book as a teacher's textbook. He emphasizes that it is the solid mental basis on which the teacher should develop his teaching, but he does not tell to whom this book addresses itself, whether to the teacher who does not know anything about linear algebra and who has to learn it from this book, or to the more advanced one who knows the subject perfectly well and will use the book to brush up his knowledge or to check it on some details. The level of this book is in between both, though even the experienced reader may be puzzled by some detail on some page n, which on page $n+100$ may be justified as a necessity of the design or as conditioned by a whim of the author.

For instance, the field of reals is introduced as an ordered field, in which real square and cube roots exist. The author admits and stresses that stronger axioms have been

omitted because they will not be needed. This is perfectly legal. However, it is not the whole truth. In the Introduction the author said that he curtailed the axiomatic system of reals in order to make it *impossible* that angles in the usual intuitive sense could be defined on the strength of the axioms. Even if the reader is able to connect a strange feature of Dieudonné's axiomatic system to that remark in the introduction, he has to wait till Appendix I to understand things clearly. But that is still not yet the whole story. Even an experienced reader may have difficulties with the secret why Dieudonné just allows the solutions of quadratic and cubic equations but of no higher ones. Faithful to the euclidean spirit, he reveals the secret only implicitly, in the last chapter where eigenvalues of 3-3-symmetric matrices are needed.

Another example: Some teacher might wonder what linear algebra can tell about areas and volumes. He will not find these words in the index or anywhere in the book. Of course Dieudonné knows what alternating bilinear forms and Gram's determinants have to do with these intuitive notions. Did he trust in some magic link by which this very essential connection would be transferred from the unconscious of the writer to that of the reader? What is the reason, a principle or a whim?

I feel embarrassed that I have to bother a mathematician I agree with in all principles of mathematical education, with such silly questions. I believe that Dieudonné's basic ideas on teaching mathematics are sound and healthier than the classical ones (if there are any) and than most of the current attempts at modernizing. It is a great pity that they are often uttered in a bizarre, preposterous and misleading way. It is more than a pity, it is a danger to base good ideas on bad arguments, particularly if it is done with Dieudonné's authority. There are people who pick up his wrong arguments to use them for bad ideas, and there are other ones who reject all good ideas which look like Dieudonné's, because Dieudonné's were based on bad arguments.

Dieudonné is completely right when attacking a kind of plane geometry instruction which can be characterized by such terms as Stewart's theorem, nine-point-circle, construction of triangles from three fanciful data, though I cannot believe that there are many class rooms in the world where such geometry is still taught. He is definitely wrong if he uses such exaggerations and degenerations, which have been the final result of a bad educational system and a wrong educational philosophy, in a way that can be understood as an argument against classical plane geometry (though it is not meant so). If one considers how in a much shorter time the same kind of excesses have developed in secondary school text books on set theory, one is inclined to conclude that it is not the subject that is wrong in our mathematics teaching but something else.

Dieudonné admits that the student has to learn geometrical constructions though he warns against the *peste* of what he calls "le plus gigantesque canular" of traditional instruction, the postulate of construction with ruler and compasses. This is a boomerang argument. The classical construction postulate means algebraically restricting to square root adjunctions. Is it much more liberal, is it an essentially less gigantic "canular" to admit both square and cube roots only as did Dieudonné, particularly if he did so with the sole aim to block the measure of angles? Of course, neither is a canular, but both are expressions of the same dogmatic spirit, which often turns antididactical, the spirit of methodical purity and systematism. There is some difference too; the classical construction postulate, though symptom of a bad philosophy, has been a source of beautiful results, while Dieudonné's is no more than a whim, even—I believe—in his own eyes.

Sometimes Dieudonné lends his ear to critical remarks. His much too complicated treatment of plane rotations is the same as given in many lectures, but finally he has yielded to criticism and at least added a paragraph on complex numbers, which was badly needed though obviously it sins gravely against methodical purity. But mostly he pretends to be blind and deaf though I firmly believe he is not. The worst example is angles.

It is a fact that in traditional instruction the word angle covers quite different notions (as the word "point" does in many different deductive systems). First, there is Euclid's notion of angle, restricted to the interval between 0 and 180 degrees, but nevertheless added up to $(n-2)\cdot 180°$ for the angles of an n-gon. There are the oriented or non-oriented angles of straight lines in "analytic" geometry which are magnitudes mod 180° and those of vectors in trigonometry which are counted mod 360°, and finally there are a few others in the geometry of space. It is a necessity that the student learns to analyze these notions and to understand their interrelations, and of course the teacher should be prepared to guide the student to this analysis. (For simplicity's sake I use designations as 180° and 360° though the foregoing has nothing to do with measuring angles.) *Measuring* angles is a quite different problem within a deductive system of geometry. If the measure is to be multiplicative, it arises easily by algebraic means from any algebraization of geometry. The usual measure, however, is additive and has to be obtained from the multiplicative one by taking logarithms. It is quite improbable that analysis (or topology) as far as needed for logarithms exceeds secondary school level, though certainly it is a heavy blow for systematism and methodical purity. So additive angle measures are banned by people who believe in these principles.

However one thinks about this point, measuring angles has nothing to do with the problems tackled in the last paragraph. After so many oral discussions and a few written explanations it is a sad thing to have them again mixed up in Dieudonné's introduction, though it is unthinkable that he should not know what is wrong in this confusion. Adding up angles beyond 360° has nothing to do with any angle measure. It simply means passing over to the universal covering group of the cyclically ordered group of angles; to construct the universal covering one needs no topology but only the cyclic order. This is as clear as it can be and it justifies in the most elementary way the usual operations on angles exorcized by Dieudonné. It is hard to understand how after all Dieudonné can propagate again and again such a confusion.

Dieudonné's activity, and particularly the present book, adds a tragedy to the challenge of modernizing mathematical education. I call it a tragedy, because Dieudonné's educational principles are the soundest of all, but instead of elaborating them he dwells on the brink of the field, where some curiosities have drawn his attention. He knows and he stresses that geometry cannot be taught by linear algebra alone, whereas many modernizers believe they can do without intuitively based geometry. Likewise Dieudonné firmly opposes those who refuse to teach more mathematics at secondary level than can be taught by the most exacting mathematical methods, which means a small amount of calculus or even no calculus at all. Instead he is realistic enough to insist on teaching as much mathematics as is needed in applications, which means, more calculus, and at an earlier age than hitherto. It is a pity that he calls the methods by which this should be done "experimental" or "physical." He still does not acknowledge that psychologically there are different levels of exactness in mathematical reasoning, and that assigning a lower bound to what may be called mathematical exactness is an artificial procedure in education. For instance, today quite a few people would not be satisfied with Dieudonné's loose use of bound variables as constants (such as ϵ in the field axioms: R7, there is an $\epsilon \neq \omega$ such that $\epsilon\zeta = \zeta$ for all ζ, and R8, for any $\zeta \neq \omega$ there is a ζ'' such that $\zeta\zeta'' = \epsilon$).

Without doubt Dieudonné would be a most competent and authoritative mathematician to tell which kind of geometry besides linear algebra and which kind of calculus should be taught and in which way it should be done. Instead he always comes back to teaching linear algebra or rather a system of linear algebra featuring mainly some oddities. He even never explains what linear algebra surrounded by all the other mathematics taught in an "experimental" way actually means. One would expect that he conceives it as an example of strictly deductive mathematics with a certain formal educa-

tional value. But the only argument Dieudonné gives, is the dogmatic statement that this is the minimum of knowledge a "bachelier ès-sciences" is expected to have when he enters the "classes propédeutiques de l'enseignement supérieur." Such statements only add to the tragic embarrassment of people who fight for modernizing mathematical instruction.

H. FREUDENTHAL, Utrecht University

Rational Mechanics. By C. W. Kilmister and J. E. Reeve. American Elsevier, New York, 1966. xi+354 pp. $9.75.

Two generations ago, every mathematician was familiar with classical mechanics, the higher parts of the subject usually were taught by mathematics departments, and some of the finest mathematicians published textbooks on analytical dynamics. Mathematicians trained since the war may well have had no contact with mechanics past a chapter or two in a required freshman physics course, and often they suffer from fantastic misconceptions regarding the contents and objectives of mathematical theories in which force, rather than mere geometry or probability, plays a part. The authors of the book under review lay blame on the textbooks, with their "completely nineteenth-century emphasis on techniques for the solution of special problems, . . . a collection of tricks with no great intellectual value. . . . "

While mechanics has almost totally disappeared from mathematics teaching and training, it has been revived as a field of modern research. This new work, some of it at a high level of mathematical abstraction, is often described by the revived term "rational mechanics," which seems to have been used little in English between the publication of Gibbs' *Statistical Mechanics* in 1901 and the foundation of the *Journal of Rational Mechanics and Analysis* in 1952. The authors' title suggests, and their preface encourages us to expect, that they will present mechanics "as the fascinating and strikingly beautiful mathematical theory that it is, . . . persuading the reader that dynamics is very much a living subject. . . . "

In fact, while some areas such as existence theory receive fuller and more scrupulous treatment than in most books, the authors do not give evidence of any contact with recent research. Even within the almost completely standard scope they have chosen, they themselves admit the logical weaknesses that any critical reader will see at once. On p. 129 they define a rigid body as a certain kind of finite system of mass points; on p. 130 they give a second definition, allowing the number of particles to be nondenumerable, and they then state that the difficulty of passing from the former theory, in which they have proved some theorems, to the latter, which most of the rest of their book concerns, is "more or less insuperable," and the matter is not made clearer when they discuss strings and chains at the end. While it comes as a welcome relief when authors of a textbook reject Newton's laws as "vague and obscure, and expositions which appear to be based on Newton's laws are really based on the unstated assumptions made in interpreting the laws," in the present case the unpromising choice of Mach as a guide for a mathematical book seems responsible for some statements vaguer and obscurer than most traditional writing, e.g.:

"Axiom 2. There exists a finite set of N particles, $N>1$, and these particles can influence each other's motion. A *particle* is an entity whose motion is completely specified by a continuous point."

There are not many mathematicians who will find this new book clearer than the standard ones, e.g. Osgood's *Mechanics* for beginners and Whittaker's *Analytical Dynamics* for the advanced. In fact, the authors make the difficulties more difficult than need be. If we can teach set theory to kindergarteners, abstract algebra to freshmen,

and functional analysis to seniors, why should the "satisfactory treatment . . . based on the theory of continuous media" be "outside the scope of the normal undergraduate syllabus" (p. 130)?

There are many special problems compactly stated, set up, and solved at various points. The main departure from older courses seems to lie in the frank discussions of some difficulties concerning constraints and friction, and in the brief treatment of the theory of impulses as a partly independent discipline. Despite the authors' intention to the contrary, the book remains a loosely connected set of interesting special cases, tastefully selected, very British and closely tied to examinations for an "honours course." It will be a welcome addition to many private and institutional libraries.

C. TRUESDELL, The Johns Hopkins University

MAA Studies in Mathematics, Vol. 3. Studies in real and complex analysis. Edited by I. I. Hirschman, Jr. Prentice-Hall, Englewood Cliffs, N. J., 1965. 213 pp. $4.00.

Volume 3 of this outstanding series of mathematical expositions more than meets the high standard set by the previous volumes.

The contents are: 1. Several Complex Variables, by H. J. Bremermann; 2. Nonlinear Mappings Between Banach Spaces, by L. M. Graves; 3. What is a Semi-group? by Einar Hille; 4. The Laplace Transform, the Stieltjes Transform and their Generalizations, by I. I. Hirschman and D. V. Widder; 5. A Brief Introduction to the Lebesgue-Stieltjes Integral, by H. H. Schaefer; 6. Harmonic Analysis, by Guido Weiss; 7. Toeplitz Matrices, by Harold Widom.

The articles are written by highly competent contributors to current mathematical developments, who have apparently given a great deal of time and thought to expressing their subjects. The incipient mathematician is fortunate, indeed, in having available this richness of material in such readable form. Moreover, the book is highly recommended reading for the professional mathematician, who will find it enjoyable and informative.

The paper by Weiss on harmonic analysis is a remarkable exposition of one of the vital areas of mathematics. It takes the reader from the beginning to an introduction to some ideas that are at the forefront today. The papers by Schaefer and Graves are beautiful presentations, quite self-contained, of important but smaller mathematical topics. The papers by Widom and by Hirschman and Widder, although narrower in scope, give the reader a feeling for the mathematical heartbeat. Those of Bremerman and Hille are elegantly written surveys of larger topics.

Finally, thanks are due to Richard V. Andree without whose persevering efforts this series would never have been started.

CASPER GOFFMAN, Purdue University

Inverse Functions. By William K. Smith. Macmillan, New York, 1966. 98 pp. $2.95.

Although the author achieves his stated purpose: "to make available to students (primarily of calculus) a reasonably complete, self-contained treatment of inverse functions, a subject which is discussed in most calculus books with distressing brevity," his book will have little appeal to the audience for whom it is intended. The fault, I think, lies in the choice of topic: whereas Professor Smith's earlier book, *Limits and Continuity*, helped clarify a concept that universally worries calculus students, few beginners are aware of gaps in the standard textbook treatment of inverse functions.

The material is uneven. The first twenty pages overexplain elementary properties of sets and functions. A student in need of such hand-holding would find the later sections too abstract. Sections 3–7, constituting the heart of the discussion, treat inverse functions both analytically and geometrically. The final section (pp. 60–80) is devoted to

trigonometric functions and the nonexistence of f^{-1}. The author's style makes his arguments easy to follow. Problems are plentiful, as are clearly-marked diagrams. Certainly a beginner in analysis would benefit from the practice provided on manipulation of functions and functional notation and from additional exposure to concepts such as monotonicity, symmetry and continuity.

WINIFRED ASPREY, Vassar College

Discourse on Fourier Series. By Cornelius Lanczos. Hafner, New York, 1966. viii+255 pp $9.85.

The subject of Fourier series is germinal. To an unusual extent, the interplay between theory and practical use has produced a growing body of knowledge with wide appeal. This discourse (and it is not a treatise nor a handbook nor a textbook but a discourse) prepared for students of mathematics, physics, and engineering on the half-graduate and graduate level is a mathematically careful history of this exciting interplay.

Especially in the beginning, very close attention is paid to elementary concepts such as 'limit,' 'uniform convergence,' and 'function.' For example, he considers in what senses 0.33333 . . . is a sum and a limit and a number. This careful keeping to the foundations pays off later. Examples that seem mere formula substitution with some authors become in his hands fresh and intuitive.

The first hundred pages include simple Sturm-Liouville problems, Fejér means, the Gibbs phenomenon, local smoothing of a series, an interesting comparison of Fourier series and Taylor series, and the usual elementary matters known to anyone who has worked with the classical vibrating string problem.

The next fifty pages include curve fitting problems, the discovery by Fourier analysis of 'hidden' properties of data, and methods of improving convergence.

The last hundred pages are on the Fourier integral and the Fourier and Laplace transforms. This last section is more difficult and the reader could profitably bring to it stronger tools such as a knowledge of asymptotic series, uniform convergence of infinite integrals, and the Cauchy integral theorem.

This good book will be of most value to those many students who know a little about Fourier series and want to know what has been happening in other aspects of the field. In attitude and content, the closest book to it is Langer's 1947 Slaught Memorial Paper, "Fourier's Series; The Genesis and Evolution of a Theory," now, lamentably, out of print. Langer has a fuller discussion of the very early history but Lanczos has a more extensive volume and includes many interesting problems. Neither book considers Lebesgue integrals or trigonometric series fitted into the setting of function spaces.

DAVID DICKINSON, University of Massachusetts

Introduction to Matrices and Linear Transformations. By Daniel T. Finkbeiner. Freeman, San Francisco and London, 1966. xi+297 pp. $7.75.

The first edition of this book has been used with great success by many graduate students as a primary reference for linear algebra. These same students may have at one time felt that the book was too simple, but continued use has shown them the depth of material in it. The second edition follows the essential format of the first, with some very useful additions.

In choosing a text for a linear algebra course, an important consideration is the background of the students. Those with limited experience in abstract mathematics should probably be introduced to linear algebra by means of familiar techniques, such as solving simultaneous linear equations. However, many present undergraduates have been exposed to "new math" and hence should be able to take a formal, axiomatic approach in stride. This text does utilize the axiomatic approach, which is particularly desirable for

those students with a serious interest in mathematics. The book is primarily a development of the *theory* of linear algebra, and not of techniques of application.

Nonetheless, both in the text and in the exercises, the applications of the theory are illustrated much more frequently than is usually found in essentially theoretical texts. For example, matrix applications in quantum mechanics, special relativity, Markov processes, linear equations, and differential equations are mentioned. The applications of linear algebra to linear programming are given the most attention. In particular, one expanded section of the second edition is on combinatorial equivalence and its role in the theory of linear programming.

Other important changes in this edition are the expansion of the discussion of metric concepts and the inclusion of some of the theory of normal matrices and transformations. And a new appendix, treating the notation appropriate to right and left hand operations, seems particularly valuable, in view of the fact that the student will likely encounter both notational systems.

K. R. REBMAN, University of Michigan

Number Theory. By Z. I. Borevich and I. R. Shafarevich. Translated by Newcomb Greenleaf for Scripta Technica. Academic, New York, 1966. x+435 pp. $12.95.

This is quite a distinctive and valuable book because it overlaps very little the other available texts on the subject in English. Written with verve and sophistication, it offers a high-level second course on the subject. (The translator's preface to the book takes a somewhat different view. "While some results from elementary number theory are occasionally used, a previous course in number theory is certainly not necessary, although the reader without such a course may have a few occasions for consulting a more elementary text.")

It is not possible to list the subject matter of the book in a brief way because of the many techniques, primarily algebraic, that are developed at great length to attack the purely number-theoretic questions. Aside from the final chapter, the topics discussed come under the headings of congruences, divisibility, and Diophantine equations, especially representation by forms. It should be added at once that these are treated in a broad framework going far beyond the discussion of integers or rational numbers. For example consider a polynomial $F(x_1, x_2, \ldots, x_n)$ with integral coefficients. At the outset of the book it is pointed out that if $F=0$ has a solution in integers, then $F\equiv 0 \pmod{m}$ is solvable for every value of the modulus m, but that the converse holds for some polynomials F but not others. To study this converse proposition the writers use such methods as the embedding of the base field of rational numbers in p-adic number fields, in algebraic fields, or in the real field, and then examining the question in the wider context. Such methods, while far from new in the literature, are not given much attention in many of the standard books on number theory.

Although algebraic techniques are central, geometric methods are also used, and in the last of the five lengthy chapters, analytic methods. The principal topic in the final chapter is the class number problem in algebraic fields.

There is an algebraic supplement of 32 pages, partly with proofs and partly without. There are many problems throughout the book, even in the algebraic supplement, most of which amount to nontrivial extensions of the theory.

IVAN NIVEN, University of Oregon

Mathematical Analysis. By L. A. Lyusternik and A. R. Yanpol'skii. Pergamon Press, Long Island City, N. Y., 1965. 404 pp. $10.00.

According to the editors, the book has been designed for the reader acquainted with the fundamentals of mathematical analysis and it will serve both as a source of information in new branches of the subject and as a digest of those with which he is already familiar. This is a correct assertion. A person who has some background in analysis

should find this a refreshing book to read, in that it develops many important topics in a precise and understandable manner. There is a clear development of ideas along with many helpful examples from which one can learn without going through the logical details of long proofs.

In the development, precise definitions are given and theorems are stated without proof. The examples given to illustrate the ideas are usually good, but a few more in crucial places would improve the book. A skillful and knowledgeable teacher could use the book effectively as a text in a course in which the techniques and methods of mathematical analysis are taught. There are no exercises.

In each chapter there is a blend of classical and modern mathematics, bringing together ideas that are not found in any one volume. Chapter I, "The Arithmetical Linear Continuum and Functions Defined There," deals in a rather sophisticated way with properties of real numbers and convergence of sequences of real numbers and of functions. Chapter II, "n-Dimensional Spaces and Functions Defined There," gives much of the material necessary for a study of functional analysis. Chapter III, "Series," on both numerical series and series of functions, gives various methods of summing series. Chapter IV, "Orthogonal Series and Orthogonal Systems," brings together many important results and includes a discussion of the classical orthogonal systems. Chapter V is an especially useful chapter on continued fractions which includes important results involving matrix methods. The last chapter is entitled, "Some Special Constants and Functions."

This volume should prove to be popular as a reference book for the mathematics teacher and for the physicist and engineer who uses the techniques of mathematical analysis.

W. G. JOHNSON, Hiram College

Some basic problems of the mathematical theory of elasticity. By N. I. Muskhelishvili Noordhoff, Groningen, Holland, 1963. xxxi+718 pp. Dfl. 57, 50.

This is a translation, by J. R. M. Radok, of the fourth Russian edition published in 1954. The first English version of the original work appeared in 1953. This edition contains numerous additions and changes, most of which are small, but at times essential. We shall list a few of the more important additions.

1. Section 41, entitled "Reduction of the fundamental problems to problems of complex function theory" has been completely rewritten and now contains an additional subsection clarifying the results for multiply connected regions.

2. In section 42, proofs of the uniqueness of regular solutions have been added.

3. Section 84, entitled "General solution of the fundamental problems for regions, mapped on to the circle by help of polynomials," contains an additional note describing how one can obtain an existence theorem in this case.

4. Section 139, some general formulas on the torsion of compound bars, now contains a proof of the fact that when the torsion function satisfies the boundary conditions, the resultant forces on the ends are zero.

This translation is admirably done and assists considerably in spreading the methods and results of Muskhelishvili outside the Soviet Union. There are, however, some annoying printers' errors in this second addition. In particular, (at least in the reviewer's copy), pages 326–327, 330–331, 334–335, and 372–373 are completely blurred. Only one part of section 138a, page 606 appears, while page 607 is exactly the same as page 620 in section 140a. Also, throughout the text various pages (i.e. 139, 460) appear in faint print. It is hoped that these errors are easily remedied.

MORTON LOWENGRUB, Wesleyan University

Introduction to functional analysis for scientists and technologists. By B. Z. Vulikh. Addison-Wesley and Pergamon Press, Reading, Mass., 1963. 397 pp. $10.00.

This book is a translation of the Russian book entitled "*Vredeniye v funktsional'nyi analiz*" published in Moscow by Fizmatgy in 1958. The title of the book is a bit misleading. There are no examples drawn from science or technology. The text appears to lack any motivational material necessary to arouse the interest of potential scientists and engineers in North American universities. Barring some rather serious translational difficulties, the text is far more suitable for the mathematics major than for a student of science or technology, but one must be extremely careful in assigning this book for students to read. There is serious misuse of the definite articles "the" and "a" throughout the book. A typical example is in the following definition found on page 165,

"DEFINITION: The complete orthonormal system of elements is said to be *the orthonormal basis* of the Hilbert space."

Chapter 6 is particularly poor in this respect.

There are many additional mistranslations or awkward translations of mathematical terms. An example of this is found in the third sentence of page 21. Also, one finds such statements as "functions of an interval" being used for a function defined over an interval, (see page 177).

In the reviewer's opinion, the book is not a total loss. There is a very nice section on the application of functional analysis to the solution of infinite dimensional linear equations, Fredholm integral equations, and Sturm-Liouville systems of differential equations.

The book is divided into thirteen chapters covering the following material: finite and infinite dimensional Euclidean spaces, metric spaces, normed linear spaces, Hilbert space, L^2 spaces, linear operators and functionals, adjoint and self-adjoint operators in Hilbert space, completely continuous operators, approximate solution of functional equations, and partially ordered normed spaces. There is a short but impressive bibliography.

MORTON LOWENGRUB, Wesleyan University

Partial Differential Equations of Mathematical Physics. By S. L. Sobolev. Translated from the third Russian edition by E. R. Dawson. English translation edited by T.A.A. Broadbent. ADIWES International Series in Mathematics. Pergamon Press, Oxford, 1964. x+427 pp. $14.00.

This is an excellent exposition of classical methods in partial differential equations. The presentation is clear, and in many instances the author goes to great length to prepare the unfamiliar reader. Only a knowledge of advanced calculus is assumed. Topics such as multiple integrals, Lebesgue integration, integrals depending on a parameter, and integral equations are developed as needed. The concept of generalized solutions is explained and motivated.

The translation is faithful; errors are few. Under present standards the book can only be recommended as an undergraduate text. It is unfortunate that it was not translated many years ago when there was a great need for books on this topic in English. In spite of the fact that the original Russian editions were published so long ago, the book remains a fine introduction to the subject.

MARTIN SCHECHTER, Institute for Advanced Study

General Theory of Functions and Integration. By Angus E. Taylor. Blaisdell, Waltham, Mass., 1965. 437 pp. $12.50.

Since there are many texts on the theory of functions and integration, another one must answer a few questions. Is it sufficient in scope? Are the examples and problems adequate? Finally and perhaps most important: in what mathematical or pedagogical way does this book differ from its predecessors?

The scope of Professor Taylor's book is certainly adequate. The basic tools of analysis are well covered. One might regret the omission of Borel structures, measures on arbitrary products, and measurability of the composition of a Borel function of k variables with a k-vector of measureable functions.

A forte of this book is its selection of examples and problems to teach and challenge. In many cases when new material is introduced, the solutions of the problems are outlined and references to the literature are given.

There are several pedagogical novelties. The theory of integration is developed twice, once through outer measures and once through the Daniell approach. Then the complete relationship between these two methods is shown. There are two chapters on general topology which would make an excellent outline for a brief undergraduate course. Chapter 9 on functions of one variable includes such things as Helly's theorem and Lebesgue's theorem on the differentiation of functions of bounded variation. It can be read independently and serve as a bridge between an elementary and more advanced course.

If a student were to choose one book from which to study integration, this book would be a good choice. He should be warned that, as with all books, the work appears of uniform color and that the short paragraph devoted to Fatou's lemma will be as important as many of the complex theorems he will encounter.

FRANK HAHN, Yale University

A Course of Higher Mathematics, Vol. V (Integration and Functional Analysis). By V. I Smirnov. Translated by D. E. Brown. Translation edited by I. N. Sneddon. Addison-Wesley (distributor for Pergamon Press), Reading, Mass., 1964. xiv+635 pp. $17.50.

The main headings in the table of contents are the following: Chapter I: The Stieltjes integral. Chapter II: Set functions and the Lebesgue integral (section 1: Set functions and the theory of measure; section 2: Measurable functions; section 3: The Lebesgue integral). Chapter III: Set functions; absolute continuity; generalization of the integral. Chapter IV: Metric and normed spaces. Chapter V: Hilbert space (section 1: The theory of bounded operators; section 2: Spaces l_2 and L_2; section 3: Unbounded operators).

The chapter on Hilbert space is by far the longest. Starting from scratch with the axioms of Hilbert space, this chapter includes a treatment of a Fredholm theorems for completely continuous (compact) operators, the spectral theorem for self-adjoint operators (bounded first, unbounded later), the corresponding operational calculus, the extension of closed symmetric operators via the Cayley transform, and Friedrichs extensions of semi-bounded operators. The treatment is classical in spirit, detailed, and illustrated with excellent, nontrivial examples. Among works covering roughly the same ground, the chapter is unusual in that it makes use of Hellinger integrals (in discussing the continuous spectrum) and generalized derivatives (in discussing examples of unbounded operators).

If the translation were improved, the exposition for the most part would be clear, detailed, and easy to follow; nevertheless, by withholding examples and explanations at strategic places, the author often does not let the reader know what is really going on.

The translation and editing are bad. Among other things, the style is wooden, many meanings are not conveyed accurately, many terms are mistranslated, many statements are mangled, typographical errors abound, the index is poor. The book is not a pleasure to read.

There are no exercises.

R. R. CHRISTIAN, The University of British Columbia

Differential Geometry on Complex and Almost Complex Spaces. By K. Yano. Pergamon Press, Macmillan, New York, 1965. xii+326 pp. $12.50.

This book is intended to serve as an introduction to differential geometry on complex and almost complex spaces, and in all respects this intention has been fully realized. Stylistically it resembles the author's earlier book on Lie derivatives, but contextually they are quite different. The notation used is fairly standard, and throughout the book free use is made of the notion of Lie derivatives.

Chapter I is a concise review (not an introduction) of the basic elements of Riemannian geometry; chapter II includes a discussion of harmonic Killing, projective Killing, and conformal Killing vectors, along with the theorem of Green. In chapter III complex spaces are introduced; the structure tensor and linear connections are defined, then a metric, leading to Hermite and Kähler spaces. Chapter IV is devoted to Kähler spaces, including a discussion of the various types of vectors and a theorem of Matsushima on the decomposition of a contravariant analytic vector, followed by a generalization by Lichnerowicz. Almost complex spaces, in particular almost Hermite and almost Kähler spaces, are introduced in chapter V, while chapter VI is concerned with linear connections on the various types of spaces. Chapters VII, VIII, and IX are devoted, respectively, to almost Kähler, almost Tachibana, and almost Hermite spaces together with the various vectors on these spaces. Chapter X deals with locally product spaces where the square of the structure tensor is $+1$ rather than -1 as in the complex case; chapter XI covers almost product spaces. The final chapter is a study of holomorphically projective transformations. Here F-connections, semisymmetric and half-symmetric connections are discussed, and other concepts such as holomorphic projective flatness and curvature are examined in this context, with applications to almost Kähler and Kähler-Einstein spaces.

The only defect that mars an otherwise excellent presentation is the number of typographical errors that occur, especially in the early chapters where the average rate is about 1 every 10 pages. Since the book is intended primarily as a reference, there are no problems or exercises included. The bibliography is extensive.

A. L. Hilt, Temple University and General Electric Co.

Linear Geometry. By Rafael Artzy. Addison-Wesley, Reading, Mass., 1965. ix+273 pp. $9.75.

This is a fine introduction to linear geometry, suitable at the advanced undergraduate and graduate levels. It is "modern" in several ways. The vocabulary and the notations are often of 20th century origin; a certain amount of algebra and algebraic methods developed in the last fifty years are presented; and the treatment has most of the time an axiomatic, hence in some sense an "abstract" and "most general" character.

The first three chapters contain an introduction to projective, affine, euclidean, elliptic, hyperbolic geometries. Coordinates over given fields are used and transformation groups play the central role in the spirit of Klein's Erlangen program. The fourth and last chapter develops geometries from geometric axioms in the spirit of Hilbert's classic "Foundations of Geometry." Of course, algebra is quickly used again. Ternary rings and loops appear. The connections between algebraic laws and geometric theorems (Desargues, Pappus) are explained. This amounts to a rather concentrated introductory text into the theory of rudimentary planes and the algebra of ternary rings. Many references are given, and I hope the interested student will be eager to use them after the study of Artzy's stimulating text.

The limitations of the book are obvious. The bulk of the work is done in two dimen-

sions. Analysis exists (the reals are introduced) but does not flourish. The geometry is linear, in some places bilinear, and the conics serve principally as sets of points which are infinitely far away, hence Pascal, Brianchon and Steiner have nothing to say. These restrictions, however, are well justified. The author offers a book of manageable size to be used as a text in a course on linear geometry treated in the algebraic way.

Finally, I cannot help but add a remark on a point which struck me and which might be of general interest apart from this particular book on linear geometry. The author refers in the text to "the German mathematician C. F. Gauss (p. 255), "the British mathematician Arthur Cayley" (p. 174), "the French mathematician Henri Poincaré" (p. 55), etc. A man's nationality is mentioned in about thirty cases, and you begin to be interested in the score (the Germans lead with 11 quotations, happily followed by 7 Americans). Should a man's nationality be mentioned in a text book of this type? In my opinion, in most cases it is not necessary and I would like to suggest not doing it at all. The repeated use of national labels might generate micro-gaullistic feelings of all sorts.

ALFRED AEPPLI, University of Minnesota

Elementary Methods in Analytic Number Theory. By A. O. Gelfond and Yu. V. Linnik. Revised and edited by L. J. Mordell. Rand McNally, Chicago, 1965. xii+242 pp. $8.75.

As the authors state in the preface, many problems of analytic number theory can be treated today by elementary methods. The object of the book is to present elementary solutions of a number of famous problems. The wealth of material treated is best indicated by the following summary. Chapter 1. Additive properties. Schnirelman's method. Theorems of Mann and Erdös. Chapter 2. Elementary solution of Waring's problem and the Hilbert-Kamke problem. Chapter 3. Distribution of primes in arithmetic progressions. The prime number theorem. Chapter 4. Distribution of Gaussian primes. Chapter 5, 6. Methods of V. Brun and A. Selberg. Chapter 7. Distribution of the fractional parts of numerical sequences. Chapter 8. Lattice point problems. Chapter 9. Distribution of power residues. Chapter 10. Yu. I Manin's proof of Hasse's theorem on the number of solutions of the congruence $y^2 \equiv x^3+ax+b \pmod{p}$. Chapter 11. Siegel's theorem concerning the number of classes of binary quadratic form with negative discriminant. Chapter 12. Transcendence of e^{ω} and α^{β}. Chapters 5 and 6 were written by A. I. Vinogradov; Chapter 10 was written by Yu. I. Manin.

It will be evident from the above that the book will be of great value to all who are interested in number theory. It is also pleasant to mention that the book is very attractive in appearance.

L. CARLITZ, Duke University

Recherches sur la Théorie Générale des Systèmes Formels. By J. Porte. Collection de Logique Mathématique, Serie A, N° 18, Gauthier-Villars, Paris, and E. Nauwelaerts, Louvain, 1965. 146 pp. 30 F.

This book starts off as a study of formal systems: deductional systems (based upon a deducibility relation), logistic systems (axioms and rules of inference), and thetic systems (theorems), in order of increasing generality. The topics covered at this level include various notions of equivalence of systems, derivability and independence of rules and axioms, properties roughly equivalent to the validity of *modus ponens* and the deduction theorem, extensions of systems, and congruence relations in the set of formulas. Then the rest (well over half) of the book is devoted to propositional calculi. Here the abstract notions of the first part are studied in concrete situations and are related to the semantic notion of a model: a set B (truth values), a subset of designated truth values, and a set of truth functions on B (corresponding to connectives of formal

systems). A chapter is given over to classical propositional calculi, especially the Łukasiewicz-Tarski system, and there is also brief mention of intuitionistic, implicational, and modal systems. Quantification theory and other more advanced topics are not treated at all.

For the most part, only simple and straightforward results are proved. For the many difficult problems which suggest themselves and for solutions of some of these problems, the reader is supplied with copious references to the literature. Nevertheless, the author's labor of definition and clarification serves a useful purpose; there are many places in logic (for example, equivalence of propositional systems involving different connectives) where a little carelessness leads to unexpected errors.

ELLIOTT MENDELSON, Queens College, Flushing, N. Y.

A Treatise on Trigonometric Series. By N. K. Bary. Translated from the Russian by Margaret F. Mullins. Macmillan, New York, 1965. Volume I, xx+553 pp. $12.00; Volume II, xv+508 pp. $15.00.

This treatise on trigonometric series appeared in Russian in 1961 and was preceded in 1959, by the two-volume second edition of Zygmund's "Treatise on Trigonometric Series." The reviewer does not propose to make any major comparison of these two standard works.

The book opens with an introductory chapter followed by an exhaustive Chapter I on the basic concepts. The material here is the standard introductory one and the 165 pages comprising it should perhaps be read by all mathematicians. The next chapter is on the nature and properties of Fourier coefficients of functions which are of bounded variation or of a Lipschitz class and includes such standard results as the Hausdorff-Young Theorem, generalized Parseval equation in L^2, and necessary conditions for a sequence to be one of Fourier coefficients. Chapter III gives, in detail, various tests for the convergence of a Fourier series at a point, while Chapter IV continues the study of the convergence of Fourier series of continuous functions and gives constructions of continuous functions whose Fourier series diverge at a set of points of cardinality $\aleph_0$ or c. Chapter V is devoted primarily to the various standard results, mainly those of Kolmogorov and Plessner, Beurling and Salem and Zygmund, and gives also examples due to Kolmogorov (respectively, Marcinkiewicz) for the existence of functions whose Fourier series are a.e. unbounded (bounded) and diverge a.e.

Chapter VI merits special attention since it gives information, not found in other books, on the following main problem: given a measurable function f and an $\epsilon>0$, is it possible to alter the function f over a set of measure $<\epsilon$ so that the new function g will have a Fourier series which converges a.e. or everywhere or uniformly? The extensive work of Menshov and his associates is summarized there.

Chapters VII thru XIII, again, contain detailed surveys of known results on the summability or strong summability, by standard summation processes, of Fourier series and conjugate trigonometric series and on the absolute convergence of Fourier series, general properties of sine and cosine series with decreasing coefficients, general trigonometric series and their convergence, divergence, etc. and lacunary series are also discussed in those chapters.

Chapters XIV and XV are again worthy of special mention. They are of a very special nature and contain several new concepts and results, many of which are those of the author herself. Chapter XIV is devoted to the problem of uniqueness of the expansion of functions by trigonometric series and the Fourier series of that sum function. A collection of open problems on this general topic is also presented at the end of the chapter. The problem of "representing" a function by trigonometric series is the theme of Chapter XV and extensive details of the works of Menshov and his associates (including the author) are found.

The first five chapters are within the reach of a specially interested first year graduate student; the value of the book to such a student is enhanced by the inclusion, at the end of these chapters, of selected problems. The remainder of the book is meant for a research worker. The principal virtues of this comprehensive work are the systematic, though slow, development of the topics discussed and the clear manner in which they are presented. The book is exceptionally well written and is self-contained. An extensive bibliography is one of its major assets. Contrasted with Zygmund's book, this work contains no major notes at the end of any chapter. As one may expect, both works have a great deal in common; however, much of the material in chapters VI, XIV and XV seem to be found only in Bary's.

Miss Bary's treatise will remain long a monumental job excellently executed by the author and gratefully received by the workers in that field.

M. S. RAMANUJAN, The University of Michigan

Elementary Differential Equations and Boundary Value Problems. By W. E. Boyce and R. C. DiPrima. Wiley, New York, 1965. 485 pp. $8.95.

Elementary Differential Equations. By W. E. Boyce and R. C. DiPrima. Wiley, New York, 1965. 361 pp. $7.75.

The second book, consisting of the first eight chapters of the first, omits the chapters on boundary value problems, Fourier series, and partial differential equations. Therefore, this will be a review of the first book.

In this subject it is not easy to tread the middle of the road between rigor and practicality. In this case, the authors have been quite successful in doing so. To be sure, not all results are proved, but all theorems are carefully stated and in almost every case some indication of the proof is given. This should give the student a sense of security with the subject. He will appreciate the basis for most results and at least know where the difficulties lie otherwise. After this treatment there should be no reason to have to brainwash any student before he goes on to advanced topics in ordinary differential equations.

The chapter on first order equations has the standard techniques and applications. There is an appendix which derives the equation of motion of a body with variable mass, an interesting problem which has applications in rocketry. This chapter also has a proof of existence and uniqueness for the initial value problem for a single first order equation based on a condition slightly less general than a Lipschitz condition. The chapter on second order linear equations begins with a nice discussion of how solutions can be obtained from linearly independent solutions of the homogeneous equation. It also contains the usual discussions of constant coefficients, variation of parameters, and undetermined coefficients. There is a separate chapter on series solutions near ordinary and regular singular points, unfortunately without general proofs of convergence. The three different cases for the roots of the indicial equation are carefully delineated and illustrated using the Bessel equation. The next three chapters are on higher order linear equations, the Laplace transform, and systems of first order equations. Enough linear algebra is introduced to make the discussion of systems quite coherent, but the general existence theorem for systems is not proved. The method of the Laplace transform is illustrated for systems. The chapter on numerical methods is better than one finds in most books on elementary differential equations. The authors carefully distinguish between local formula error, accumulated formula error, and round-off error, and they compare the efficiency of several methods in terms of local formula error. The last three chapters are on boundary value problems, Fourier series, and the separation of variables method of solving certain second order partial differential equations.

Probably because of the lack of discussion of various special functions, there is a heavy emphasis in the last three chapters on problems which lead to trigonometric

eigenfunctions. Perhaps this is inevitable in an elementary course, but one wonders if it would be possible to introduce some additional problems based on the Bessel functions or the Legendre functions. Also, the concept of the Green's function seems so important that it should not be relegated to the problems. These are just minor criticisms of an otherwise well conceived and well executed book. The authors are to be commended for helping to upgrade the literature in an area where often in the past "cookbooks" have been all too common.

J. W. DETTMAN, Oakland University

Topics in Algebra. By I. N. Herstein. Blaisdell, Waltham, Mass., 1964. 350 pp. $8.50.

This is an excellent text designed for an honors section in algebra, but the manner in which it is written makes it possible to teach a course at several different levels. By amplifying the proofs, going over them thoroughly in class, and assigning the problems intended to illustrate the theory, one can gear the course to the average student. The above average student could be encouraged to work on the "not too obvious problems." Another good exercise is to have the students puzzle out the proofs for themselves.

The book has many attractive features. The problems are excellent, varying from the immediate to those one had best not assign unless he had a few weeks spare time to work on them himself. Many theorems are proved in two or three different ways and in varying degrees of generality depending upon the context in which they occur. Most important, the author demands a lot of the student; and, if the instructor supports the author in this demand, the student will learn a great deal from the book.

Most important of all, I enjoyed teaching a course with this text.

ROBERT ELLIS, Wesleyan University

Number Theory. By J. Hunter. Oliver and Boyd, Edinburgh and London, 1964. 149 pp. $2.75.

This elegant little book is one of the "University Mathematical Texts." In the introductory chapter there is an excellent, if brief, informal discussion of the systems of positive integers, all integers, rational numbers, equivalence relations, groups, rings and fields. There are six more chapters. They deal with division and factorization properties of the integers, congruences, algebraic congruences and primitive roots, quadratic residues, representation of integers by binary quadratic forms and some diophantine equations. An attempt is made in various parts of the book to exhibit the close relation between certain parts of number theory and properties of finite abelian groups and commutative rings.

The book developed out of lecture courses in number theory given to students of mathematics at Glasgow University at various stages of an honors course. A strong student who has had a course in modern algebra can read the little book on his own with profit. The author is not long-winded. His proofs on occasion are extremely terse. In my opinion the writing is too condensed for the usual number theory course given in this country, and there are not enough problems. Each chapter has only one problem list appearing at the end of the chapter.

SOLOMON HURWITZ, City College, City University of New York

Einführung in die Wahrscheinlichkeitsrechnung und mathematische Statistik. By D. Morgenstern. Springer-Verlag, Berlin-Göttingen-Heidelberg, 1964. 224 pp. DM 34.50.

This book has many virtues; among them are a clear and effective presentation of the standard material of mathematical statistics, numerous examples, a wealth of good exercises, and a method of presentation which stresses motivation and intuition.

It is organized in two parts, the first dealing with discrete distributions and the second

with continuous distributions. This leads to a certain amount of logical redundancy, but pays handsome dividends in readability and in keeping statistical motivation in the foreground. For example, the central limit theorem is proved for a number of special cases in part 1 and in a general form in part 2.

Anyone using this book, either as a textbook or for self study, might profitably supplement it with one of the standard texts on probability theory. The author does not usually state theorems separately, so they must be extracted from the body of the text; in fact, some of the hypotheses turn up in the footnotes.

The book contains more than the average number of misprints and inconsistencies of notation, and some of the references are rather incomplete. In spite of these difficulties the book is a valuable one and the minor irritations are more than outweighed by the author's insight into the basic problems of mathematical statistics.

TOM PITCHER, University of Southern California

Mathematical Theory of Connecting Networks and Telephone Traffic. By V. E. Beneš. Academic Press, New York, 1965. xiv+319 pp. $12.00.

This work would best be titled "A Selection of Reprints on Telephone Networks," since except for Chapter 3, it is an almost word for word reprint of papers published in the *Bell Systems Technical Journal* [Chap. 1, vol. 41, p. 1201; Chap. 2, vol. 41, p. 1249; Chap. 4, vol. 32, p. 406; Chap. 5, vol. 36, p. 939; Chap. 6, vol. 40, p. 117; Chap. 7, vol. 42, p. 567; Chap. 8, vol. 42, p. 2795]. This is unfortunate in several ways, especially since it is never explicitly mentioned and since Chap. 4 is essentially the writing of C. Clos. Of more concern to the reader are the facts that: (1) it is a bit hard to understand the beginning without having read the middle (notations are not clearly introduced until well into the book, etc.), (2) it is divided into somewhat isolated portions, (3) it is very specialized and omits alternate approaches (as graph theory synthesis) and applications (as to air traffic routes). On the other hand the ideas treated are fascinating and represent extremely useful applications of somewhat advanced mathematics. For example a typical portion of the book, Chap. 3, is concerned with representation of telephone connecting networks through permutation groups; if appropriate group factorizations were on hand this would lead to economical synthesis of such networks.

The work represents what appears as a conscientious effort to combine engineering concepts with a rigorous mathematical treatment. As such it is fairly successful, but the reader does need considerable background in probability and group theory with some knowledge of topology being useful.

In summary, the work will most likely become a useful reference to workers in the telephone industry. Still, the lack of editorial effort is regrettable; with relatively little editing it could become a classic reference on very practical uses of semiabstract mathematics.

R. W. NEWCOMB, Stanford University

Linear Equations and Matrices. By J. B. Johnston, G. B. Price and F. van Vleck. Addison-Wesley, Massachusetts, 1966. 308 pp. $8.50.

This is an elementary text with an emphasis on matrix algebra and its applications. Basic concepts are clearly defined and are accompanied by examples which give added meaning to the explanations. Considerable attention is given to computational procedures. Students interested in a good understanding of the mathematical development of the subject must pay close attention to the problems in the book.

The topics treated are: systems of linear equations, algorithms, flow charts, and matrices and their applications.

B. VISWANATHAN, University of New Brunswick

TELEGRAPHIC REVIEWS

The following abbreviations indicate suggested uses: T (textbook), S (supplementary student reading), P (professional reading for the teacher), TT (teacher training), L (library purchase), 15 (junior level)—18 (second graduate year).

Algebra

Lectures on Real and Complex Vector Spaces. By Frank S. Cater. Saunders, Philadelphia, 1966. x+167 pp. $5.00. Twenty-eight lectures, most followed by problems, divided into five subsets: fundamental concepts, matrices, determinants, operators, operators on vector spaces, finite dimensional vector spaces, finite-dimensional unitary spaces. T (15–17), S, P.

Linear Transformations and Matrices. By F. A. Ficken. Prentice-Hall, Englewood Cliffs, N. J. 1967. xii+398 pp. $10.95. Preliminaries (sets, logic, real numbers, classical algebra and geometry of vectors in "naive physical space," algebraic structures), linear spaces, transformations, functionals, duality, matrices, linear systems, matric equivalence, bilinear and guadratic functionals and forms, determinants, similar operators, unitary space, 760 problems, and bibliography. The publishers, a few years behind in their homework, announce on the dust jacket that the author has served as Associate Editor of this MONTHLY. T (13–15), S. P.

Algebraic Structures. By Serge Lang. Addison-Wesley, Reading, Mass., 1967. vii+169 pp. $6.95. Another in what is becoming a *lang* series of short books, this volume complements the author's *Linear Algebra* and could be used independently or for half (preferably the second half) of a year course. Topics include the integers, groups, rings, polynomials, vector spaces and modules, field theory, the real and complex numbers, sets (through cardinals, well-ordering, proof of Zorn's lemma). "The desire to avoid encyclopedic proportions, and specialized emphasis, and to keep the book short, explains the omission of some theorems which some teachers will miss and may want to include in the course." T (14–15).

The Abstract Theory of Groups. By the late O. U. Schmidt. Translated from the Russian by Fred Holling and J. B. Roberts. Edited by J. B. Roberts. Freeman, San Francisco, 1966. vi+174 pp. $5.00. This translation of Schmidt's classic work of 1916 is based on the 2nd edition of 1933 which differed from the first by "only insignificant editorial changes." The editor offers it for its "selection of topics . . . treatment . . . numerous historical references" and describes it as a "beautiful book." In his preface (1933) Schmidt observed that only one comprehensive treatise (Burnside) existed when he wrote in 1916 and that between the two editions there were only two "noteworthy books of general nature" (Speiser and Miller-Blickfeldt-Dickson). One notes that Schmidt signs his preface of 1933 on the Icebreaker Chelyuskin, and Roberts signs his of 1966 in Dar es Salaam, Tanzania. S. P. L.

Introduction to Linear Programming, with Applications. By William R. Smythe, Jr. and Lynwood A. Johnson. Prentice-Hall, Englewood Cliffs, N. J., 1966. vii+221 pp. $9.00. Topics from linear algebra, algebraic solutions of linear programming problems (simplex method), networks and flows, applications. T (14–15), S.

Analysis

Transcendental Functions Satisfying Nonhomogeneous Linear Differential Equations. By A. W. Babister. Macmillan, New York, 1967. xi+414 pp. $14.95. Methods of finding particular integrals and "a comprehensive treatment" of their properties, including results published for the first time in book form. Presupposes an elementary course in differential equations. There are problem sets. T, S, P.

Differential and Difference Equations. By Louis Brand. Wiley, New York, 1966. xvi+698 pp. $11.95. Not just another book on its subjects, but a parallel treatment of difference and differential equations bringing out similarities in both theory and methods of procedure. The inspiration of Maxime Bôcher's course at Harvard on linear differential equations of the second order is acknowledged by the author. Topics include the Laplace transform, solution in series, Mikusinski's operational calculus, existence and uniqueness theorems, and numerical methods. T (15–17), S, P, L.

Problems in Differential Equations. By J. L. Brenner. Freeman, San Francisco, 1966. ix+172 pp. $2.50. (paper). To the first edition have been added two appendices, one on the formalism of the Laplace transform and one giving a "logically complete discussion of the existence and uniqueness of the solution of a linear differential equation with constant coefficients . . . without using the ideas of Wronskian and linear dependence." T (14), S.

The Theory of Cluster Sets. By E. F. Collingwood and A. J. Lohwater, Cambridge University Press, New York, 1966. xi+211 pp. $8.50. An introductory treatise on cluster sets, a notion first introduced by Painlevé in 1895. (The cluster set of a function at a boundary point of its domain is the set of limit points of the function there.) Bibliography. P, L.

Introduction to Analysis and Abstract Algebra. By John E. Hafstrom. Saunders, Philadelphia, 1967. xii+344 pp. $6.50. Logic, the ordered field of real numbers and its subsets, completeness, sets, relations, mappings, operations, groups, rings, integral domains, fields, construction of the real numbers, sequences, point sets, limits, continuity, integration, polynomials and continuous functions—in short "what every young mathematician ought to know" by the end of his junior year at least. T (14–15), S.

Linear Differential Equations and Function Spaces. By José Luis Massera and Juan Jorge Schäff. Academic, New York, 1966. xx+404 pp. $16.00. A treatise "presenting in systematic and detailed form the recent studies of the authors concerning linear ordinary differential equations in the real domain" based "on an idea going back to the work of O. Perron (1930) . . . " Assumes no special knowledge of differential equations but a working acquaintance with Banach-space theory, both "soft" and "hard" (not including operatory theory). P.

Multiple Integrals in the Calculus of Variations. By Charles B. Morrey, Jr. Springer-Verlag, New York, 1966. xii+506 pp. $19.50. A comprehensive treatise based on the author's research over more than three decades. P, L.

Infinite Series. By Earl D. Rainville. Macmillan, New York, 1967. xii+265 pp. $7.95. The usual topics in an elementary introduction plus uniform convergence, orthogonal sets of functions, Fourier series, asymptotic series, infinite products and much material not included in the sketchy treatment offered in the usual calculus course. T (14–15), S.

Value Distribution Theory. By Leo Sario and Kiyoshi Noshiro. Van Nostrand, Princeton, N. J., 1966. xi+256 pp. $7.50. A "modern value distribution theory for complex analytic mappings between abstract Riemann surfaces" inspired by classical value distribution theory, which was initiated by Picard's celebrated theorem, "one of the most beautiful results in classical analysis," and was further developed by Borel, Hadamard, Valiron, Julia, Collingwood, Littlewood, and others. There are historical remarks and an extensive bibliography. P, L.

Introductory Complex Analysis. By Richard A. Silverman. Prentice Hall, Englewood Cliffs, N. J., 1967. xi+372 pp. $8.75. The author describes this as a scaled-down version of the three volume translation *Theory of Functions of a Complex Variable* by A. I. Markushevich of Moscow State University, published by Prentice-Hall under his editorship 1965–1967. The distillation is intended for the "usual one-year graduate course" given in the United States. T (17).

Applications

Space Mathematics, Parts I, II, III. Volumes 5, 6, 7 of Lectures in Applied Mathematics. American Mathematical Society, 1966. I: 315 pp. $12.80. II: 258 pp. $12.80. III: 315 pp. $12.80. Twenty-seven papers based mostly on lectures at the 1963 Summer Seminar in Applied Mathematics and covering "current state of research . . . pressing unsolved problems . . . mathematical techniques which are currently useful in attacking" problems on the behavior of non-propulsive space vehicles. P, L.

Fourier Transforms and the Theory of Distributions. By J. Arsac. Translated by Allen Nussbaum and Gretchen C. Heim. Prentice Hall, Englewood Cliffs, N.J., 1966. xv+318 pp. $12.75. ". . . I have tried to merge the viewpoints of the mathematicians and the physicists and run the middle course between extreme rigor and none at all . . ." Topics include transforms of summable functions and square-summable functions, modified distributions and their transforms, multidimensional space, diffraction at infinity, complex impedances, applications in mathematics physics, linear filters, numerical methods. S, P.

Mathematical Methods in the Physical Sciences. By Mary L. Boas. Wiley, New York, 1966. xix+778 pp. $11.95. ". . . coverage that includes nearly every area of mathematical physics needed in the junior, senior, and first year of graduate work . . ." Series, complex numbers, determinants and matrices, partial derivatives and multiple integrals, vector analysis, Fourier series, ordinary and partial differential equations, calculus of variations, special functions, transformations and tensor analysis, complex functions, series solutions, integral transforms, probability. T (14). Reviewed in *Science* 24 March 1967.

A Deductive Theory of Space and Time. By Saul A. Basri. North Holland, Amsterdam, 1966. xi+163 pp. $7.00. "The theory starts with the primitive concept of the class of living humans and ends with the derivation of the equations of motion of a particle in an arbitrary gravitational field." Making use of the "fruitful and exciting developments in mathematics during the last half century," particularly symbolic logic, that "have not been utilized in physics to the extent they could," the author "develops the concepts of particles, events, clocks, length measuring instruments, and all other concepts of space-time geometry in terms of only eight primitive concepts." P.

Mathematical Systems Theory. A new serial published quarterly by Springer Verlag, New York. Executive Editors: D. Bushaw, A. J. Lohwater, M. D. Mesarovic, and G. P. Szegö. ". . . will feature articles in such fields as topological dynamics, theory of dynamical polysystems, general systems theory, formal systems theory, mathematical theory of automata and algorithms, mathematical linguistics, algebraic systems theory, ergodic theory, several aspects of qualitative theory of differential equations and the like. In addition, papers in functional analysis, topology, algebra and logic directed related to the theory of mathematical systems will be published." Did they overlook anything?

Stochastic Processes. By M. Girault. Vol. III of Econometrics and Operations Research. Springer-Verlag, New York, 1966. ix+122 pp. $7.00. "The practical worker must . . . have at his disposal a set of original and varied stochastic models . . ." Poisson pro-

cesses, numerical processes with independent random increments, Markov processes, Laplace processes and second order processes, processes on continuous-time. S, P.

Mathematical Theory of Elementary Particles. Proceedings of the Conference held at Endicott House, in Dedham, Mass. Sept. 12–15, 1965. Edited by Roe Goodman and Irving Segal. M.I.T. Press, Cambridge, Massachusetts, 1966. vii+188 pp. $6.00. Thirteen papers representing "a quite broad spectrum of mathematical approaches" including papers by "quantum field theorists of both axiomatic and constructivist persuasions (some of whom have legs in both outposts): and group-theoretical single-particleers." The editors express the hope that the volume "has sufficient breadth, topicality, and elementary clarity to be useful for orientation purposes, as well as of interest to experts . . ." P.

An Introduction to Dynamic Programming. The Theory of Multistage Decision Processes. By O. L. R. Jacobs. Chapman & Hall, London, 1967. x+123 pp. Obtainable in U.S.A. only from Barnes and Noble, New York. $5.50. A simple introduction, requiring only elementary calculus and based on examples, to the theories initiated by the work of R. E. Bellman in the 1950's. S, P.

Econometric Techniques and Problems. By C. E. Leser. Hafner, New York, 1966. viii+119 pp. $4.45 (Paper). ". . . based on a course of lectures which were held . . . at the Economic Research Institute, Dublin, in the winter of 1963–64. Participants . . . were mainly university students of economics in their honours year and economics graduates in the public service, in business, and in research institutes . . . will be of interest to a wider public . . . who wish to get a good grasp of what econometrics is and how it is used." S, P.

Formulas and Theorems for the Special Functions of Mathematical Physics. By Wilhelm Magnus, Fritz Oberhettinger, and Raj Pal Soni. Third enlarged edition. Springer-Verlag, New York, 1966. vii+508 pp. $16.50. A new and enlarged English edition of the book that originally appeared in German in 1946. The gamma, hypergeometric, Bessel, Legendre, Kummer's, Whittaker, parabolic, parabolic cylinder, theta, elliptic and incomplete gamma functions, orthogonal polynomials, elliptic integrals, integral transforms, coordinate transformations. L.

The Mathematical Apparatus for Quantum-Theories, Based on the Theory of Boolean Lattices. By Otton Martin Nikodym. Springer-Verlag, New York, 1966. x+952 pp. $36.00. "The purpose of this book is to give the theoretical physicist a geometrical, visual and precise mathematical apparatus . . . based on the theory of Boolean lattices, whose elements are closed subspaces in the separable and complete Hilbert-Hermite-space." This is a systematic synthesis of the author's work beginning with his paper of 1947 (see *Zentralblatt*, vol. 37 (1951) 278). The price of 3.7¢ per page for quality printing and binding of material with a high density of formulas and special symbolism contrasts favorable with the 7¢ a page charged for some recent books produced by cheaper methods. P, L.

The Method of Summary Representation for Numerical Solution of Problems of Mathematical Physics. By G. N. Polozhii. Translated from the Russian by G. J. Tee. Translation edited by K. L. Stewart. Pergamon, New York, 1965. xx+283 pp. $10.00. "The book will be useful to scientific workers and engineers who are interested in the numerical solution of problems of mathematical physics and technology, particularly in those cases where the accuracy of an approximate solution is a matter of great importance." P.

Great Ideas in Information Theory, Language and Cybernetics. By Jagjit Singh. Dover, New York, 1966. ix+338 pp. $2.00 (paper). A popularization of interest to mathe-

maticians by the author of *Great Ideas of Modern Mathematics* and of *Great Ideas and Theories of Modern Cosmology*, which were honored by the UNESCO Kalinga Prize for outstanding achievement in the dissemination of science. S, P, L.

Boundary Value Problems of Mathematical Physics. Vol. I. By Ivar Stakgold. Macmillan, New York, 1967. viii+340 pp. $12.95. This first volume deals with the mathematics required for the methods of eigenvalue expansion and Green's function and with applications to ordinary differential and integral equations. The second will deal with partial differential equations. Prerequisites are advanced calculus and elementary complex variables. T (17, science and engineering), P.

Applied Methods of the Theory of Random Functions. By A. A. Sveshnikov. Translated by J. Berry. Translation edited by L. Haller. Pergamon, New York, 1966. ix+321 pp. $10.00. ". . . methods are presented of random functions analysis with their applications in various branches of technology: in the theory of ships, in the theory of automatic regulation and control, in radio engineering and so on . . . the mathematical rigour of the treatment has been pursued only to the extent to which it is necessary for understanding the text and for obtaining a mastery of the methods given . . . intended for engineers and scientists . . ." General properties, spectral theory, optimal dynamical systems, experimental methods for determining characteristics, method of envelopes. P.

Mathematics of Automatic Control. By Toshie Takahashi. Translated by Scripta Technica, Inc. Translation edited by George M. Kranc. Holt, Rinehart and Winston, New York, 1966. xx+454 pp. $14.50. Transient response, frequency response, functions of complex variables, Laplace transformation, transfer functions, stability. ". . . for beginners intending to understand the essential interconnection between the mathematical theory of complex functions and dynamical theory of linear control systems. This book has grown out of my lectures on applied mathematics for students of mechanical engineering . . ." T (15–16), S, P.

Spacetime Physics. By Edwin F. Taylor and John Archibald Wheeler. Freeman, San Francisco, 1966. 208 pp. $4.75. Though "developed for the first month of a freshman physics course," it is of interest because it provides "an introduction to relativity and brings closer the time when the student of physics will be as much at home with the geometry of spacetime as the student in an earlier century was with Euclidean geometry." P, L.

Topology

Topology Seminar Wisconsin. Edited by R. H. Bing and R. J. Bean. Princeton Univ. Press, Princeton, N.J. 1966. 246 pp. $5.00. "This volume contains the proceedings of the topology seminar held under the direction of R. H. Bing at the University of Wisconsin in the summer of 1965. Most of the articles were presented as talks to the topologists assembled, then expanded to make expository articles with the details of proofs frequently omitted . . ." P, L.

Elements of Mathematics, General Topology, Parts 1 and 2. ByNicolas Bourbaki. Addison-Wesley, Reading, Mass., 1966. I: 438 pp. $18.50. II: 368 pp. $18.50. The first two of eight planned volumes in which the publishers, with the gracious permission of M. Bourbaki, plan to issue an English revised version of the thirty-one paperbound booklets in which *Les Eléments* has appeared piecemeal and profoundly affected contemporary mathematical thinking. The identical price for volumes of significantly different size illustrates once more the arbitrary pricing policies of publishers when

offering books that they estimate (correctly in this case!) must be bought by libraries. (Addison-Wesley informs us that the price was set by the French publisher and is approximately equal to the total cost of the original edition when bought in separate pamphlets.) P, L.

First Concepts of Topology. The Geometry of Mappings of Segments, Curves, Circles, and Disks. Number 18 in the New Mathematical Library. By W. G. Chinn and N. E. Steenrod. Random House and Singer, New York, 1966. viii+160 pp. $1.95 (paper). Although written for high school students and laymen, this series is of such high quality that it belongs in any mathematician's library. This volume deals with existence theorems in one and two dimension in order to "show how topology arose, develop a few of its elements, and present some of its simpler applications." P, L.

Topological Groups. By L. S. Pontryagin. Translated from the Russian by Arlen Brown. Gordon & Breach, New York, 1966. xv+543 pp. $32.50 (ref) $17.50 (pro). ". . . does not demand . . . a broad mathematical knowledge . . . (only) significant mathematical maturity . . . a knowledge of the most elementary mathematical material, such as analytic geometry, the theory of matrices, the theory of ordinary differential equations, etc." For a cheaply produced photo-offset book the price of 6¢ a page is outrageous!

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Dr. S. M. Ulam, Professor of computing science and mathematics at the University of Colorado, has received an Alfred Jurzykowski Foundation Polish Millennium Award for science.

Arizona State University: Mr. C. W. Arnquist, University of California, has been appointed Assistant Professor; Associate Professors J. B. Kelly and N. W. Savage have been promoted to Professors.

California State Polytechnic College: Assistant Professor T. J. Cullen, California State College, has been appointed Assistant Professor; Mr. Albert Konigsberg has been promoted to Assistant Professor; Assistant Professor E. J. Vought has been promoted to Associate Professor; Associate Professors K. B. Kriege and H. F. Simmons have been promoted to Professors.

City College of New York: Associate Professors Solomon Hurwitz and Abraham Schwartz have been promoted to Professors.

Dartmouth College: Associate Professor R. Z. Norman has been promoted to Professor; Assistant Professor W. E. Slesnick has been promoted to Associate Professor; Assistant Professor G. W. Day has been appointed Assistant Professor at the University of Wyoming; Dr. J. E. Graver has been appointed Assistant Professor at Syracuse University.

University of Dayton: Mr. J. W. Friel, University of Nebraska, has been appointed Assistant Professor; Dr. T. E. Gantner, Purdue University, has been appointed Assistant Professor; Dr. R. C. Steinlage, Ohio State University, has been appointed Assistant Professor.

Dominican College: Sister Agnes Rose Kokke has been promoted to Assistant Professor and Chairman of the Mathematics Department; Assistant Professor Sister Mary David Kutchey has been appointed Chairman of the Mathematics Department at St. Catherine's High School.

Eastern Kentucky University: Associate Professor B. R. Lane, George Peabody College, has been appointed Professor and Chairman of the Mathematics Department; Associate Professor F. G. Scorsone has been promoted to Professor.

Louisiana State University: Dr. W. L. Bynum, University of North Carolina, has been appointed Assistant Professor; Dr. R. L. Pendleton, Massachusetts Institute of Technology, has been appointed Assistant Professor; Assistant Professor J. R. Retherford has been promoted to Associate Professor.

New York University: Associate Professor Melvin Hausner has been promoted to Professor; Dr. V. G. Vitale, New York University, has been appointed Assistant Professor.

Ohio University: Dr. I. A. Barnett, University of Cincinnati, has been appointed Visiting Professor; Mr. Hari Shankar has been promoted to Assistant Professor.

University of Oregon: Dr. L. C. Grove, John Wesley Young Research Institute, has been appointed Assistant Professor; Assistant Professors G. W. Struble and C. R. Wright have been promoted to Associate Professors; Associate Professor F. W. Anderson has been promoted to Professor.

St. John Fisher College: Assistant Professor D. L. Muench, U. S. Naval Academy, has been appointed Associate Professor; Miss Helen B. Boulas has been promoted to Assistant Professor and Acting Chairman of the Mathematics Department.

San Diego State College: Dr. E. J. Howard, Idaho State University, has been appointed Assistant Professor; Dr. R. P. Kopp, University of Michigan, has been appointed Assistant Professor; Assistant Professors H. A. Gindler and Betty Kvarda have been promoted to Associate Professors; Associate Professor Margaret F. Willerding has been promoted to Professor.

Southern Illinois University: Assistant Professor R. E. Hughs, Carleton College, has been appointed Associate Professor; Mr. L. S. Holden has been promoted to Assistant Professor; Assistant Professor R. B. Rutledge has been promoted to Associate Professor.

State University of New York at Binghamton: Assistant Professor E. P. Rozycki, Canisius College, has been appointed Assistant Professor; Dr. N. J. Sterling, Syracuse University, has been appointed Assistant Professor; Professor W. R. Transue, Kenyon College, has been appointed Professor.

Professor Emeritus V. G. Grove, Michigan State University, died on January 23, 1967. He was a member of the Association for forty-seven years.

Dr. Jack Indritz, University of Minnesota, died on November 30, 1966. He was a member of the Association for fourteen years.

Professor Emeritus Eugenie M. Morenus, Sweet Briar College, died on October 15, 1966. She was a Charter Member of the Association.

Mr. G. A. Seubert, Supervising Principal, Unity Township School District, died on December 3, 1966. He was a member of the Association for forty-four years.

Professor C. A. Shook, Lehigh University, died on December 28, 1966. He was a member of the Association for fifty years.

Professor A. K. Snyder, Valley Forge Military Jr. College, died on December 29, 1966. He was a member of the Association for seventeen years.

PUBLICATION OF *EDUCATION IN APPLIED MATHEMATICS*

The Society for Industrial and Applied Mathematics has available reprints of the proceedings of a Conference sponsored by SIAM under a grant from the National Science Foundation at Aspen, Colorado, May 24–27, 1966. The proceedings were published as part of the April 1967 issue of the *SIAM Review*. Topics include: Objectives of Applied Mathematics Education; The Mathematics Curriculum; The Science Curriculum; Training in Applied Mathematics Research; The Research Program in Applied Mathematics; and, Post Doctoral Experience. Only a limited number of reprints are still available at the special price of $2.40 each. Orders should be addressed to: SIAM, 33 S. 17th Street, Philadelphia, Pa. 19103. Payment should accompany order.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

MARCH MEETING OF THE SOUTHERN CALIFORNIA SECTION

The forty-seventh meeting of the Southern California Section of the MAA was held at San Diego State College, San Diego, California, on March 11, 1967. The registered attendance was 128, including 107 members of the Association. Professor V. C. Harris, Chairman of the Section, presided at the morning and afternoon sessions.

At the business meeting Dr. R. E. Horton, Chairman of the Nominating Committee, reported the election of the following officers, who are to serve beginning July 1, 1967: Chairman, Professor F. A. Valentine, University of California, Los Angeles; Vice-Chairman, Professor C. W. Seekins, Occidental College; Secretary-Treasurer, Professor D. H. Potts, San Fernando Valley State College. The Chairman and Vice-Chairman will serve for one year; the Secretary will serve for three years. The following members of the Program Committee for the 1968 meeting of the Section were also elected: Professor Richard Dean, Cal Tech, Chairman; Professors Courtney Coleman, William Lambert, L. J. Paige, and Sidney Spital.

Professor R. C. James reported as Governor for the Section on items and actions of the Board of Governors for the January, 1967 meeting at Houston, Texas. Dr. J. M. Huffman of the Office of Schools for San Diego County, reported on the National High School Mathematics Contest, as conducted in the Section by the Committee on the High School Contest. There was increased participation on the part of schools and their students in southern California, especially in the San Diego area. Many schools are benefitting from the program.

It was announced that the next meeting of the Section is scheduled to be held on March 9, 1968, at Loyola University of Los Angeles.

The following program was presented:

1. *Distributions in n-dimensions whose support is a point*, by Leon Nower, San Diego State College, introduced by the Secretary.

The concepts of distribution and support, and associated fixed-point theorems, were discussed for two-dimensional examples, and for higher dimensions.

2. *Digital bracelets*, by Dean C. W. Trigg, retired, Los Angeles City College.

A bracelet is one period of a simply periodic series considered as a closed sequence with terms equally spaced around a circle. Application to exhaustion of the 100-pair set of ordered digits by $u_{n+2}=u_n+u_{n+1}$ produces six digital bracelets. Operation of one bracelet on another by addition (reduced modulo ten) causes rotation or conversion. The recurrence $u_{n+2}=au_n+bu_{n+1}$ produces plain bracelets when $a=1, 3, 7, 9$. Bracelet digits have 1-digit charms attached for even a, and odd b. Charms are bifurcated for a, b even. Bracelet digits are multicharmed when $a=5$, $b\neq 5$, with quinfurcation of charms when $a=b=5$. In systems with prime number bases, all bracelets are plain.

3. *Remarks on Banach's contraction mapping principle*, by J. B. Diaz, University of California, Riverside, introduced by the Secretary.

The talk was based on the paper: "Remarks on a generalization of Banach's principle of contraction mappings," by Sherwood C. Chu and J. B. Diaz, Journal of Mathematical Analysis and Applications, Vol. 11, 1965, pp. 440–446, where it is shown that a generalization of Banach's principle of contraction mappings is a special case of an elementary fact. The contraction mapping principle appears in the book: *Elements of the Theory of Functions and Functional Analysis*, Volume I, *Metric and Normed Spaces*, by S. Banach.

4. *Course work for the general college student*, a panel discussion chaired by C. J. A. Halberg, Jr., University of California, Riverside, concerning recommendations of the W. L. Duren panel of CUPM.

The discussion centered around a three-page report which had been submitted to members of the Section. In general the Committee concurs with the Duren Panel, but it suggests that problems peculiar to the junior college and to students qualified for advanced placement, are in need of further study, with regard to the area of mathematics in general education.

5. *Correlation properties of sequences*, by L. R. Welch, University of Southern California.

This talk iilustrated applications of finite fields and quadratic forms over finite fields, to communication theory. Sequences defined by linear recurrences with constant coefficients over $GF(2)$ are of interest to communications engineers, and the analysis of such sequences is a natural extension of the customary analysis over the field of real numbers. Properties of interest are periodicity, autocorrelation, and cross-correlation for sequences. The first two properties are easily predicted, using extension fields of $GF(2)$. Although the last property is generally more difficult, for a special class of cross-correlations, it can be reduced to considering quadratic forms over $GF(2^n)$.

6. *Dihedral groups arising in Fourier transform theory*, by R. W. Preisendorfer, Research Mathematician, Scripps Institute of Oceanography, University of California, San Diego.

The operations of taking a Fourier transform T, complex conjugator C, and reversal in the real line R, with $T\cdot T=R$, form a *dihedral group* of order eight. The elements of the group are in the set, $\{I, T, R, R\cdot T, C, T\cdot C, R\cdot C, \text{and } C\cdot T\}$. There are two related groups of four elements: a cyclic group generated by T, and a *four group*, $\{I, R, T\cdot C, C\cdot T\}$. The dihedral group has been used to generate many variations of convolution, Parseval, and power spectrum theorems.

R. B. HERRERA, *Secretary-Treasurer*

SUMMER DUES PAYMENTS

Since dues in the Association are payable on a calendar year basis, the Buffalo office is faced each year with a great overload of work in December and January since so many members pay their annual dues at that time.

It would help to spread the work of the office and to reduce the cost of operation if most members would pay dues in advance during the preceding summer. We suggest, therefore, that members plan to pay their 1968 dues of $8 sometime this summer. Payments should be sent to: Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, N. Y. 14214.

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN

ILLINOIS

INDIANA

IOWA, Wartburg College, Waverly, Spring 1968.

KANSAS

KENTUCKY

LOUISIANA-MISSISSIPPI, Mississippi State College for Women, Columbus, February 16–17, 1968.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA

MISSOURI

NEBRASKA, Nebraska Center for Continuing Education, Lincoln, April 26–27, 1968.

NEW JERSEY

NORTHEASTERN

NORTHERN CALIFORNIA

OHIO

OKLAHOMA-ARKANSAS, Federal Aviation Agency, Oklahoma City, March 29–30, 1968.

PACIFIC NORTHWEST

PHILADELPHIA, University of Delaware, Newark, Delaware, November 18, 1967.

ROCKY MOUNTAIN

SOUTHEASTERN, East Carolina College, Greenville, North Carolina, March 29–30, 1968.

SOUTHERN CALIFORNIA, Loyola University of Los Angeles, Los Angeles, March 9, 1968.

SOUTHWESTERN, New Mexico State University, University Park, Spring 1968.

TEXAS, Texas A&M University, College Station, April 19–20, 1968.

UPPER NEW YORK

WISCONSIN

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, New York, December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, Toronto, Ontario, Canada, August 29–Sept. 1, 1967.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION

ASSOCIATION FOR COMPUTING MACHINERY Sheraton-Park, Washington, D. C., August 29–31, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC, Sheraton-Boston Hotel, December 27–28, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, McGill University, Montreal, August 21–24, 1967.

OPERATIONS RESEARCH SOCIETY OF AMERICA, Sheraton-Chicago Hotel, November 1–3, 1967.

PI MU EPSILON, Toronto, Ontario, Canada, August 29–30, 1967.

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, University of California at Santa Barbara, November 29–December 2, 1967. (Symposium on combinatorial mathematics.)

Paperback Supplements for Fall Classes

Probability

John Lamperti, Dartmouth College
152 Pages Paper $.95/$3.16 prepaid*
Cloth: $8.00/$6.40 prepaid*

This short survey for graduate students gives an overview summation of independent random variable, and introduces current problems concerning stochastic processes.

Calculus on Manifolds

Michael Spivak, Brandeis University
158 Pages Paper: $2.95/$2.36 prepaid*
Cloth: $7.00/$5.60 prepaid*

This sophomore-junior text centers about a modern approach to Stokes' theorem and presents parts of advanced calculus influenced by modern differential geometry.

Plateau's Problem

Frederick J. Almgren, Jr.,
Princeton, University
88 Pages Paper: $2.95/$.36 prepaid*
Cloth: $7.00/$5.60 prepaid*

The new language for the expression of many geometric concepts provided by measure theoretic surfaces called "varifolds" is introduced through an examination of "Plateau's Problem."

An Introduction to Fourier Series and Integrals

Robert T. Seeley, Brandeis University
120 Pages Paper: $2.95/$2.36 prepaid*
Cloth: $7.00/$5.60 prepaid*

This text introduces Fourier series in approximately the way Fourier used them, as solutions of the heat equation in a disk.

MAA Studies in Mathematics

A series intended to bring to the mathematical community expository articles at the collegiate and graduate level on recent developments in Mathematics. This new volume will be published in the summer of 1967.

Volume 4: *Studies in Global Geometry and Analysis*

Edited by S. S. Chern

Introduction	S. S. Chern
What is analysis in the large?	Marston Morse
Curves and surfaces in euclidean space	S. S. Chern
Differential forms	Harley Flanders
On conjugate and cut loci	S. Kobayashi
Surface area	Lamberto Cesari
Integral geometry	L. A. Santalo

Each individual member of MAA may purchase one copy of Volume 4, as well as one copy of each of Volumes 1, 2, 3 for $3 per volume. Orders with payment should be sent to:

Mathematical Association of America
SUNY at Buffalo (University of Buffalo)
Buffalo, New York 14214

Additional copies and copies for nonmembers may be purchased for $6 from Prentice-Hall, Inc., Englewood Cliffs, New Jersey 07631.

UNIQUE IN MATHEMATICS BOOKS

Mathematics and Computing:
with FORTRAN Programming

By WILLIAM S. DORN, *International Business Machines; and*
HERBERT J. GREENBERG, *University of Denver.*

UNIQUE because it introduces computer programming and computing in the context of a course in mathematics. The book covers essential topics in linear systems of equations and inequalities with optimization, intuitive calculus, probability and logic. The book is full of problems based on realistic applications. The use of the computer in the context of mathematics allows the reader to solve problems, develop insights, and make discoveries in mathematics which otherwise would not be possible.

A few of the book's special features: uses the computer to further mathematical understanding; the programming is simple FORTRAN and will run on *any* computer with a FORTRAN compiler; an Instructor's Manual with marginal notes and solutions to *all* exercises including programming exercises. *1967. 595 pages. $8.95.*

Calculus
An Intuitive and Physical Approach
In two parts

By MORRIS KLINE, *The Courant Institute of Mathematical Sciences, New York University*

UNIQUE because it presents the subject intuitively and relates it as closely as possible to science. The book is consistently intuitive—in the justification of the theorems and techniques; in the use of geometrical, physical, and heuristic arguments and generalizations from concrete cases; and in the emphasis on discovery in mathematics. And the book is strong on applications with real problems to motivate and introduce the mathematics; applications to genuine physical problems once the mathematics is developed; and an organization that allows applications to be introduced almost from the beginning. Yet no knowledge of science is presupposed.

The style of writing is informal and the mathematical steps are given in great detail so the reader should be able to follow the development with ease. Part 1: *1967. 574 pages. $9.95.* Part 2: *1967. 415 pages. $8.95.*

THE AMERICAN MATHEMATICAL MONTHLY

(FOUNDED in 1894 BY BENJAMIN F. FINKEL)

R. A. ROSENBAUM, *Editor*

EDITORIAL CORRESPONDENCE AND MANUSCRIPTS OF PAPERS should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

THIS IS THE OFFICIAL JOURNAL OF THE

MATHEMATICAL ASSOCIATION OF AMERICA, INC.

(Devoted to the Interests of Collegiate Mathematics)

General Office: SUNY at Buffalo, Buffalo, N. Y. 14214. *Executive Director:* H. M. GEHMAN

OFFICERS OF THE ASSOCIATION

President, E. E. MOISE, Harvard University
Past-President, R. L. WILDER, University of Michigan
First Vice-President, G. S. YOUNG, Tulane University
Second Vice-President, R. J. WALKER, Cornell University
Editor, R. A. ROSENBAUM, Wesleyan University
Secretary, H. L. ALDER, University of California, Davis
Treasurer, H. M. GEHMAN, State University of New York at Buffalo
Associate Secretary, RAOUL HAILPERN, State University of New York at Buffalo

Additional Members of the Board of Governors: R. W. BALL, JOSHUA BARLAZ, R. G. BARTLE, GRACE BATES, DOROTHY L. BERNSTEIN, R. H. BING, D. W. BLAKESLEE, R. N. BRADT, PAUL BURCHAM, E. A. CAMERON, E. J. CAMP, R. B. DEAL, K. W. FOLLEY, D. B. GOODNER, EMIL GROSSWALD, C. J. A. HALBERG, JOSEPH HASHISAKI, A. P. HILLMAN, P. S. JONES, VICTOR KLEE, H. M. MACNEILLE, N. H. MCCOY, D. W. MILLER, J. M. H. OLMSTED, F. D. PARKER, C. R. PHELPS, G. B. PRICE, P. K. REES, ABRAHAM SCHWARTZ, L. L. SCOTT, M. F. SMILEY, F. M. STEIN, A. F. STREHLER, A. W. TUCKER, C. J. VANDERLIN, JR., D. W. WALL, G. N. WOLLAN, MARTIN WRIGHT.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00 ($8.00 in 1968). For nonmembers the subscription price is $10.00 ($15.00 in 1968).

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July,
August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

THE WILLIAM LOWELL PUTNAM MATHEMATICAL COMPETITION

J. H. McKAY, Oakland University and University of California, Berkeley

The following results of the twenty-seventh William Lowell Putnam Mathematical Competition held on November 19, 1966, have been determined in accordance with the regulations governing the Competition. This competition is supported by the William Lowell Putnam Intercollegiate Memorial Fund left by Mrs. Putnam in memory of her husband and is held under the auspices of the Mathematical Association of America.

The first prize, five hundred dollars, is awarded to the Department of Mathematics of Harvard University, Cambridge, Massachusetts. The members of the team were Douglas E. Burke, Irwin Gaines, and Neal I. Koblitz; to each of these a prize of fifty dollars is awarded.

The second prize, four hundred dollars, is awarded to the Department of Mathematics of Massachusetts Institute of Technology, Cambridge, Massachusetts. The members of the team were Theodore C. Chang, Gerald S. Gras, and Michael R. Rolle; to each of these a prize of forty dollars is awarded.

The third prize, three hundred dollars, is awarded to the Department of Mathematics of University of Chicago, Chicago, Illinois. The members of the team were James Coulthard, Louis L. Crane, and Dennis A. Hejhal; to each of these a prize of thirty dollars is awarded.

The fourth prize, two hundred dollars, is awarded to the Department of Mathematics of University of Michigan, Ann Arbor, Michigan. The members of the team were Ronald J. Evans, Robert L. Scott and Paul E. Weiss; to each of these a prize of twenty dollars is awarded.

The fifth prize, one hundred dollars, is awarded to the Department of Mathematics of Princeton University, Princeton, New Jersey. The members of the team were James K. Baker, Daniel I. A. Cohen and Robert J. Weber; to each of these a prize of ten dollars is awarded.

The five persons ranking highest in the examination, named in alphabetical order, are Marshall W. Buck, Harvard University; Theodore C. Chang, Massachusetts Institute of Technology; Robert E. Maas, University of Santa Clara; Richard C. Schroeppel, Massachusetts Institute of Technology; and Robert S. Winternitz, Massachusetts Institute of Technology. To each of these a prize of seventy-five dollars is awarded.

The ten persons ranking second highest in the examination, named in alphabetical order, are Gerald S. Gras, Massachusetts Institute of Technology; Ronald A. Hunsinger, Humboldt State College; Neal I. Koblitz, Harvard University; William L. Lepowsky, Harvard University; Theodore S. Martner, University of Colorado; Roger E. Poore, Carleton College; William F. Prange, University of Nebraska; Robert L. Scott, University of Michigan; John C. Stewart, Virginia Polytechnic Institute; and William G. Unruh, University of Manitoba.

The following teams, named in alphabetical order, won honorable mention: California Institute of Technology, the members of the team being Glenn E. Engebretsen, Kim D. Gibson and Stacy G. Langton; Clarkson College of Technology, the members of the team being John G. Alvord, David Boss, and Philip C. Washburn; Dartmouth College, the members of the team being J. Lawrence Carter, Sidney W. Marshall, and David L. Salsbury; Stanford University, the members of the team being A. Craig Franklin, Alan R. Siegel, and Andrew J. Vince; and Swarthmore College, the members of the team being Mary E. Kramer, John C. Mather and Stephen B. Maurer.

Honorable mention is given to the following twenty individuals, named in alphabetical order: Roger K. Alexander, University of Kansas; Clifton L. Anderson, Yale University; Douglas E. Burke, Harvard University; J. Lawrence Carter, Dartmouth College; James E. Coulthard, University of Chicago; Paul R. Dippolito, Kenyon College; Glenn E. Engebretsen, California Institute of Technology; Robert M. Ephraim, Columbia University; Gerald B. Folland, Harvard University; Robert S. Fowler, Swarthmore College; Irwin Gaines, Harvard University; Jacob B. Gross, Yeshiva University; Michael E. Grost, Michigan State University; Christopher A. Gurwood, New York University; John R. Hall, Jr., Brown University; Douglas A. Lind, University of Virginia; John M. Malcolm, Harvey Mudd College; Stephen B. Maurer, Swarthmore College; William C. Mitchell, California Institute of Technology; and Pieter B. Visscher, Harvard University.

One thousand five hundred twenty-six contestants from two hundred fifty-one colleges and universities participated in the examination on November 19, 1966.

A listing of the top five hundred contestants may be obtained from the Director. The list, which includes addresses and expected dates of graduation, may be helpful to departments of mathematics in selecting graduate students.

The Questions Committee, consisting of A. M. Garsia (chairman), R. E. Greenwood, and N. D. Kazarinoff, prepared the problems (listed below) for the competition.

PROBLEMS PART A

A-1. Let $f(n)$ be the sum of the first n terms of the sequence 0, 1, 1, 2, 2, 3, 3, 4, $\cdots$, where the nth term is given by

$$a_n = \begin{cases} n/2 & \text{if } n \text{ is even,} \\ (n-1)/2 & \text{if } n \text{ is odd.} \end{cases}$$

Show that if x and y are positive integers and $x>y$ then $xy=f(x+y)-f(x-y)$.

A-2. Let a, b, c be the lengths of the sides of a triangle, let $p=(a+b+c)/2$, and r be the radius of the inscribed cricle. Show that

$$\frac{1}{(p-a)^2}+\frac{1}{(p-b)^2}+\frac{1}{(p-c)^2}\geqq\frac{1}{r^2}.$$

A-3. Let $0<x_1<1$ and $x_{n+1}=x_n(1-x_n)$, $n=1, 2, 3, \cdots$. Show that

$$\lim_{n\to\infty} nx_n = 1.$$

A-4. Prove that after deleting the perfect squares from the list of positive integers the number we find in the nth position is equal to $n+\{\sqrt{n}\}$, where $\{\sqrt{n}\}$ denotes the integer closest to $\sqrt{n}$.

A-5. Let C denote the family of continuous functions on the real axis. Let T be a mapping of C into C which has the following properties:

1. *T is linear*, i.e. $T(c_1\psi_1+c_2\psi_2)=c_1T\psi_1+c_2T\psi_2$, for c_1 and c_2 real and ψ_1 and ψ_2 in C.

2. *T is local*, i.e. if $\psi_1 \equiv \psi_2$ in some interval I then also $T\psi_1 \equiv T\psi_2$ holds in I.
Show that T must necessarily be of the form $T\psi(x) = f(x)\psi(x)$ where $f(x)$ is a suitable continuous function.

A-6. Justify the statement that

$$3 = \sqrt{1+2\sqrt{1+3\sqrt{1+4\sqrt{1+5\sqrt{1+\cdots}}}}}.$$

PART B

B-1. Let a convex polygon P be contained in a square of side one. Show that the sum of the squares of the sides of P is less than or equal to 4.

B-2. Prove that among any ten consecutive integers at least one is relatively prime to each of the others.

B-3. Show that if the series

$$\sum_{n=1}^{\infty} \frac{1}{p_n}$$

is convergent, where $p_1, p_2, p_3, \cdots, p_n, \cdots$ are positive real numbers, then the series

$$\sum_{n=1}^{\infty} \frac{n^2}{(p_1 + p_2 + \cdots + p_n)^2} p_n$$

is also convergent.

B-4. Let $0 < a_1 < a_2 < \cdots < a_{mn+1}$ be $mn+1$ integers. Prove that you can select either $m+1$ of them no one of which divides any other, or $n+1$ of them each dividing the following one.

B-5. Given $n(\geqq 3)$ distinct points in the plane, no three of which are on the same straight line, prove that there exists a simple closed polygon with these points as vertices.

B-6. Show that all solutions of the differential equation $y'' + e^x y = 0$ remain bounded as $x \to \infty$.

SOLUTIONS. PART A

The number in parentheses, immediately following the problem number, is the number of participants who received a score of 8, 9 or 10 on the problem. The maximum possible score on a problem is 10.

A-1 (840) It is easily verified by induction that

$$f(n) = \begin{cases} n^2/4 & \text{when } n \text{ is even,} \\ (n^2 - 1)/4 & \text{when } n \text{ is odd.} \end{cases}$$

Therefore, since $x+y$ and $x-y$ always have the same parity, in any case we must have

$$f(x+y) - f(x-y) = \frac{(x+y)^2 - (x-y)^2}{4} = xy.$$

A-2 (34) The area of the given triangle can be calculated in two ways, $A = pr$ and $A = \sqrt{p(p-a)(p-b)(p-c)}$. Squaring and equating we get $p^2r^2 = p(p-a)(p-b)(p-c)$. Setting $x = 1/(p-a)$, $y = 1/(p-b)$, $z = 1/(p-c)$ we can write this equation in the form

$$\frac{1}{r^2} = pxyz = xyz\left(\frac{1}{x}+\frac{1}{y}+\frac{1}{z}\right).$$

Thus we need only show that $yz+xz+xy \leqq x^2+y^2+z^2$. However this follows from the trivial inequalities $y^2+z^2 \geqq 2yz$, $x^2+z^2 \geqq 2xz$, $x^2+y^2 \geqq 2xy$.

A-3 (6) Multiplying the defining relation by $(n+1)$ we get

$$(1) \qquad (n+1)x_{n+1} = nx_n + x_n - (n+1)(x_n)^2 = nx_n + x_n[1-(n+1)x_n].$$

To prove that nx_n is increasing, we need to show that $1-(n+1)x_n \geqq 0$. From the graph of $x(1-x)$ we note that $x_2 \leqq \frac{1}{4}$ and that $x_n \leqq a \leqq \frac{1}{2}$ implies $x_{n+1} \leqq a(1-a)$. So by induction,

$$(n+1)x_n \leqq (n+1)\frac{1}{n}\left(1-\frac{1}{n}\right) = 1-\frac{1}{n^2} \leqq 1.$$

Furthermore, $nx_n < (n+1)x_n \leqq 1$ and so nx_n is bounded above by 1. Thus nx_n converges to a limit α with $0 < nx_n < \alpha \leqq 1$. Now summing (1) from 2 to n we obtain

$$(2) \qquad \begin{aligned} 1 &\geqq (n+1)x_{n+1} \\ &= 2x_2 + x_2(1-3x_2) + x_3(1-4x_3) + \cdots + x_n[1-(n+1)x_n]. \end{aligned}$$

If $\alpha \neq 1$ then $[1-(n+1)x_n] \geqq (1-\alpha)/2$ for all large n and thus (2) would show that $\sum x_n$ is convergent. However $nx_n \geqq x_1$ and so $\sum x_n \geqq x_1 \sum(1/n)$.

A-4 (160) To prove the formula by induction, it suffices to show that the difference $\Delta = n+\{\sqrt{n}\}-(n-1+\{\sqrt{n-1}\}) = 1$ or 2, with the value 2 occurring if and only if the number $n+\{\sqrt{n-1}\}$ is a perfect square. For convenience, let $\{\sqrt{n-1}\} = q$. Then of course $q-\frac{1}{2} < \sqrt{n-1} < q+\frac{1}{2}$ or better $q^2-q+\frac{1}{4} < n-1 < q^2+q+\frac{1}{4}$. This gives $q^2+5/4 < n+\{\sqrt{n-1}\} < (q+1)^2+\frac{1}{4}$. Therefore the number $n+\{\sqrt{n-1}\}$ is a perfect square if and only if $n=(q+1)^2-q$. However, then and only then $\sqrt{n} > q+\frac{1}{2} > \sqrt{n-1}$. In other words then and only then $\{\sqrt{n}\}-\{\sqrt{n-1}\} = 1$, because this difference is never greater than 1.

A-5 (17) We shall show that $T\psi(x) = f(x)\psi(x)$ for all $\psi \in C$, where f is the image under T of the function 1 which sends x into 1. For each x_0 and ψ, define ψ' by

$$\psi'(x) = \begin{cases} \psi(x) & \text{if } x \leqq x_0, \\ \psi(x_0) & \text{if } x > x_0. \end{cases}$$

Since T is local we must have $T\psi'(x) = T\psi(x)$ for all $x \leqq x_0$. On the other hand, for $x > x_0$, $T\psi'(x) = \psi(x_0)T1(x) = \psi(x_0)\cdot f(x)$. By continuity of $T\psi'$, $T\psi(x_0) = \psi(x_0)\cdot f(x_0)$.

Comment: The condition (1) is needed only in the case where $c_2 = 0$. Also the interval I in condition (2) should be required to have positive measures since the problem is trivial if I can be taken as a point.

A-6 (1) We understand the statement to mean that

$$3 = \lim_{n\to\infty} \sqrt{1 + 2\sqrt{1 + 3\sqrt{1 + \cdots \sqrt{1 + (n-1)\sqrt{1+n}}}}}.$$

We see that

$$3 = \sqrt{1 + 2\cdot 4} = \sqrt{1 + 2\sqrt{16}} = \sqrt{1 + 2\sqrt{1 + 3\sqrt{25}}}$$
$$= \sqrt{1 + 2\sqrt{1 + 3\sqrt{1 + 4\sqrt{36}}}}.$$

This leads us to conjecture the relation

$$3 = \sqrt{1 + 2\sqrt{1 + 3\sqrt{1 + \cdots + \sqrt{1 + n\sqrt{(n+2)^2}}}}} \quad \text{for all } n \geqq 1.$$

Proceeding by induction we verify that $(n+2)^2 = n^2+4n+4 = 1+(n+1)(n+3)$ $= 1+(n+1)\sqrt{(n+3)^2}$. This given, we must have

$$3 \geqq \sqrt{1 + 2\sqrt{1 + 3\sqrt{\cdots \sqrt{1 + (n-1)\sqrt{(1+n)}}}}}.$$

To set an inequality in the other direction, observe that for any $\alpha > 1$

$$\sqrt{1 + n\alpha} \leqq \sqrt{\alpha}\sqrt{1+n}.$$

A repetition of this inequality gives then

$$3 \leqq (n+2)^a \sqrt{1 + 2\sqrt{1 + 3\sqrt{1 + \cdots \sqrt{1 + (n-1)\sqrt{1+n}}}}}, \quad \text{where} \quad a = 2^{1-n}.$$

SOLUTIONS. PART B

B-1 (278) Let $P_1, P_2, \cdots, P_n$ be the vertices of P. Let $P_1', P_2', \cdots, P_n'$ be the projections of $P_1, P_2, \cdots, P_n$ upon one of the sides of the squares, and let $P_1'', P_2'', \cdots, P_n''$ be the projections of $P_1, P_2, \cdots, P_n$ upon a side that is orthogonal to the previous one. Since P is convex, the first side will be covered at most twice by the segments $\overline{P_1'P_2'}, \cdots, \overline{P_{n-1}'P_n'}, \overline{P_n'P_1'}$. We thus deduce the inequality $\overline{P_1'P_2'}^2 + \cdots + \overline{P_n'P_1'}^2 \leqq 2$. Similarly $\overline{P_1''P_2''}^2 + \cdots + \overline{P_n''P_1''}^2 \leqq 2$. Adding these two inequalities and using the Pythagorean theorem the assertion follows.

B-2 (343) Any common factor of two of such numbers would have to be divisible by 2, 3, 5 or 7. So it is sufficient to prove that among any ten consecutive integers there is at least one that is not divisible by 2, 3, 5 or 7. We get such an integer by elimination as follows. Strike out those divisible by 3. There may be either 3 or 4 of them. Among these there is either at least one or two respectively that are divisible also by 2. Thus if we strike off also those that are divisible by 2 we will have eliminated at most seven of the integers. Note that by so doing we have stricken off at least one number divisible by five. Thus we are left with three integers only two of which can be divisible by 5 or 7.

B-3 (0) Set $q_n = p_1 + p_2 + \cdots + p_n (q_0 = 0)$. We are led to estimate $S_N = \sum_{n=1}^{N} (n/q_n)^2 (q_n - q_{n-1})$ in terms of $T = \sum_{n=1}^{\infty} 1/p_n$. Note that

$$S_N \leqq \frac{1}{p_1} + \sum_{n=2}^{N} \frac{n^2}{q_n q_{n-1}} (q_n - q_{n-1}) = \frac{1}{p_1} + \sum_{n=2}^{N} \frac{n^2}{q_{n-1}} - \sum_{n=2}^{N} \frac{n^2}{q_n}$$

$$= \frac{1}{p_1} + \sum_{n=1}^{N-1} \frac{(n+1)^2}{q_n} - \sum_{n=2}^{N} \frac{n^2}{q_n} \leqq \frac{5}{p_1} + 2\sum_{n=2}^{N} \frac{n}{q_n} + \sum_{n=2}^{N} \frac{1}{q_n}.$$

By Schwarz's inequality,

$$\left(\sum_{n=2}^{N} \frac{n}{q_n}\right)^2 \leqq \sum_{n=2}^{N} \frac{n^2}{q_n^2} p_n \sum_{n=1}^{\infty} \frac{1}{p_n}$$

and thus

$$S_N \leqq \frac{5}{p_1} + 2\sqrt{S_N T} + T.$$

This quadratic inequality implies that $\sqrt{S_N} \leqq \sqrt{T} + \sqrt{2T + 5/p_1}$.

B-4 (15) Let, for each $1 \leqq i \leqq mn+1$, n_i denote the length of the longest chain, starting with a_i and each dividing the following one, that we can select out of $a_i, a_{i+1}, \cdots, a_{mn+1}$. If no n_i is greater than n then there are at least $m+1$ n_i's that are the same. However, the integers a_i corresponding to these n_i's cannot divide each other, because $a_i \mid a_j$ implies that $n_i \geqq n_j + 1$.

B-5 (144) Let these points be denoted by $P_1, P_2, \cdots, P_n$. To every permutation $(\sigma_1, \sigma_2, \cdots, \sigma_n)$ of $(1, 2, 3, \cdots, n)$ we associate a closed polygon, namely $P_{\sigma_1}P_{\sigma_2} \cdots P_{\sigma_n}P_{\sigma_1}$. This way we obtain $(n-1)!$ distinct closed polygons some of which may have selfintersections. We claim that anyone of these polygons whose length is the shortest possible is simple. By the hypothesis that no three P_i's are on the same line, a selfintersection occurs if and only if two segments say $\overline{P_{\sigma_1}P_{\sigma_2}}$ and $\overline{P_{\sigma_m}P_{\sigma_{m+1}}}$ cross each other. However, then the closed polygon $P_{\sigma_2} \cdots P_{\sigma_{m-1}}P_{\sigma_m}P_{\sigma_1}P_{\sigma_n}P_{\sigma_{n-1}} \cdots P_{\sigma_{m+1}}P_{\sigma_2}$ would have shorter length. Thus there can't be a cross if the length of $P_{\sigma_1} \cdots P_{\sigma_n}P_{\sigma_1}$ is shortest possible.

Alternate solution: Take two points P_1 and P_2 such that all the other points $P_3, P_4, \cdots, P_n$ are on the same side of the line connecting P_1 and P_2. Each point P_i, $i>2$, determines an angle θ_i between P_1P_2 and P_1P_i, with $0<\theta_i<\pi$. By hypothesis, $\theta_i \neq \theta_j$ if $i \neq j$. Let $(i_3, i_4, \cdots, i_n)$ be the permutation of $(3, 4, \cdots, n)$ such that $\theta_{i_3} < \theta_{i_4} < \cdots < \theta_{i_n}$. Then $P_1P_2P_{i_3}P_{i_4} \cdots P_{i_n}P_1$ is a closed simple polygon.

B-6 (0) Multiplying the equation by $e^{-x}y'$ and integrating from 0 to T we get, after rearranging terms,

$$y^2(T) + 2\int_0^T e^{-x}y'y''\,dx = y^2(0).$$

Note then that for some $0 \leqq \zeta \leqq T$ we must have

$$2\int_0^T e^{-x}y'y''\,dx = 2\int_0^\zeta y'y''\,dx = \{y'(\zeta)\}^2 - \{y'(0)\}^2.$$

We then obtain $y^2(T)+\{y'(\zeta)\}^2=y^2(0)+\{y'(0)\}^2$.

METRIC POSTULATES FOR SPACE GEOMETRY

ROLAND BROSSARD, Université de Montréal

1. Introduction. Metric postulates for plane geometry have been given by Saunders MacLane in [4]. We shall show that it is also possible to define high school space geometry in a very similar way, leaving open the possibility of extension to higher dimensional spaces. More precisely, this is an attempt to find a simple and intuitive set of facts relating distances and angles which will suffice to characterize space geometry. The axioms are formulated in such a way as to exhibit a certain symmetry between the distance (measure of segments) and the measure of angles. They consist of four existence or incidence axioms, five axioms on distance, five axioms on angles, the continuity axiom, and the similarity axiom. We shall prove that the axioms in [5] are theorems or axioms in the axiomatic structure given here, and consequently the proof given in [5] for categoricity establishes the categoricity of the system of axioms given here. The development outlined below is oriented toward this proof of categoricity, and would have indeed no interest for high school teaching.

2. Primitive notions. *Points* are abstract undefined objects. Primitive terms are: point, distance, line, ray or half-line, half-bundle of rays, and angular measure. The set of all points will be denoted by the letter S and some subsets of S are called *lines*. The plane as well as the three-dimensional space shall not be taken as primitive terms but will be constructed.

3. Axioms on points, lines, and distance. The axioms on the points and on the lines are:

E_1. *There exist at least two points in S.*
E_2. *A line contains at least two points.*
E_3. *Through two distinct points there is one and only one line.*
E_4. *There exist points not all on the same line.*

A set of points is said to be *collinear* if this set is a subset of a line. Two sets are *collinear* if the union of these sets is collinear.

The axioms on distance are:

D_1. *If A and B are points, then $d(AB)$ is a nonnegative real number.*

D_2. *For points A and B, $d(AB)=0$ if and only if $A=B$.*

D_3. *If A and B are points, then $d(AB)=d(BA)$.*

For distinct points A,B,C, B is *between* A and C if and only if $d(AB)+d(BC)=d(AC)$. If B is between A and C we write $[A, B, C]$. If $A\neq B$, the class of points P between A and B is the *interval* AB. If $A\neq O$, the class of points $P\neq O$ such that $d(AP)=|d(OA)-d(OP)|$ is the *ray* OA (or *half-line* OA). O is the *end-point* of the ray OA. We have furthermore the two following axioms concerning the distance.

D_4. *Three distinct points belong to a line if and only if one of them is between the other two.*

D_5. *On each ray OA and for each positive real number β there exists a point B such that $d(OB)=\beta$.*

We have then in [4] the proof of the following theorem.

THEOREM 1. (a) *If $[O, A, B]$ then interval OA is contained in the interval OB,*

(b) *on each ray OA and to each positive real number β there exists exactly one point B such that $d(OB)=\beta$,*

(c) *if $A\neq O$ and $B\in$ ray OA, then ray $OA=$ ray OB,*

(d) *two rays with the same end-point are either equal or disjoint,*

(e) *if O is a point of a line l, then l contains exactly two disjoint rays with end-point O and each point $P\neq O$ of l belongs to exactly one of these rays,*

(f) *on a line l, for every distinct points O and A there exists a one-to-one mapping x of l onto the set of real numbers such that $x(O)=0$, $x(A)>0$, and for all points P, Q of l $d(PQ)=|x(P)-x(Q)|$,*

(g) *a point Q lies between P and R if and only if either $x(P)<x(Q)<x(R)$ or $x(R)<x(Q)<x(P)$.*

If O is a point of a line l, we know that there exist exactly two distinct rays with end-point O; any one is *opposite* to the other. If r is a ray, the opposite ray is denoted $\bar{r}$. Parts (f) and (g) of Theorem 1 imply that the betweenness relation has the usual properties. We shall group under Theorem 2 the properties of the betweenness relation that will be used later.

THEOREM 2. (a) $[A, B, C]$ *and* $[B, C, D]$ *imply* $[A, B, D]$,

(b) $[A, B, C]$ *and* $[B, D, C]$ *imply* $[A, B, D]$,

(c) $[A, B, C]$ *implies* $[C, B, A]$,

(d) $[A, B, C]$ *implies* $\sim[B, C, A]$ (*not* $[B, C, A]$),

(e) $[A, X, B]$ *and* $[A, Y, B]$ *imply* $[A, X, Y]$ *or* $[A, Y, X]$,

(f) *if $A\neq B$, then there exists a point C such that* $[A, B, C]$.

4. The axioms on angles, half-bundles, and the continuity axiom. An *angle* is an ordered couple of rays with the same end-point. The rays are the *sides* of the angle and the common end-point is the *vertex* of the angle. An angle is *flat* in case the sides are distinct and belong to a line. We shall introduce the measure $\angle rs$ of an angle rs with the axioms A_1, A_2, A_3. The measure of an angle is intuitively conceived as the number obtained with the use of a protractor. If $A \neq O$ and $B \neq O$, we write $\angle AOB$ for $\angle(\text{ray } OA)(\text{ray } OB)$.

A_1. *If rs is an angle, then $\angle rs$ is a real number such that $0 \leqq \angle rs \leqq 180$.*

A_2. *For an angle rs, $\angle rs = 0$ if and only if $r = s$.*

A_3. *If rs is an angle, then $\angle rs = \angle sr$.*

A *half-bundle* ab, where a and b are rays with the same end-point not belonging to a line, is the class of rays x such that $x \neq a$ and $\angle bx = |\angle ab - \angle ax|$. The common end-point of the rays is the *vertex* of the half-bundle. For the half-bundle ab we use the notation HB_{ab}. A ray b is *between* the rays a and c if and only if a, b, c have a common end-point, no two of them belong to a line, and $\angle ab + \angle bc = \angle ac$; if b is between a and c we write $[a, b, c]$. With those notations we have that $x \in HB_{ab}$ if and only if $[a, b, x]$ or $[a, x, b]$ or $x = b$.

The axioms on the half-bundles are:

A_4. *Three distinct rays a, b, c belong to a half-bundle if and only if one of them is between the other two.*

A_5. *If β is a real number between 0 and 180, then there exists on each half-bundle HB_{oa} one ray b such that $\angle ob = \beta$.*

We shall now add the so-called continuity axiom.

CONTINUITY AXIOM. *If $[a, b, c]$ and if A, C are points on rays a and c respectively, then there exists a point B on ray b such that $[A, B, C]$. Conversely, if a and c are noncollinear rays with the same end-point O, $A \in a$, $C \in c$, and if B is such that $[A, B, C]$ then the ray $OB = b$ is between the rays a and c (i.e. $[a, b, c]$).*

We have used the word "betweenness" for the ternary relation $[a, b, c]$; we shall now justify this terminology and prove that this relation defined on the elements of a half-bundle has the properties of the formal betweenness relation as defined for instance in [3]. Those properties coincide also with those of the betweenness relation for the points of a line as mentioned in section 3.

THEOREM 3. *The betweenness relation for the elements of a half-bundle has the characteristic properties of the formal betweenness relation, that is to say,*

(a) *$[a, b, c]$ implies that a, b, c are distinct and belong to a half-bundle,*

(b) *if a, b, c are distinct elements of a half-bundle, then $[a, b, c]$ or $[b, c, a]$ or $[c, a, b]$,*

(c) *$[a, b, c]$ implies $\sim[b, c, a]$,*

(d) *if $[a, b, c]$ then $[c, b, a]$,*

(e) $[a, b, c]$ *and* $[b, d, c]$ *imply* $[a, b, d]$,
(f) *if* $[a, b, c]$ *and* $[b, c, d]$ *then* $[a, b, d]$.

Proof. (a) and (b) are immediate consequences of axiom A_4, and the definition of the betweenness relation for the rays. To prove (c) and (d) we consider the rays a, b, c such that $[a, b, c]$. The continuity axiom implies the existence of points A, B, C on rays a, b, c respectively such that $[A, B, C]$. If $[a, b, c]$ and $[b, c, a]$, then $[A, B, C]$ and there exists a point $C' \in c$ such that $[B, C', A]$, but as A, B, C, C' are collinear points, $C = C'$ and we have a contradiction; consequently $[a, b, c]$ implies $\sim[b, c, a]$. Moreover $[A, B, C]$ implies $[C, B, A]$ and the continuity axiom implies $[c, b', a]$, but as B is on b and on b', then $b = b'$ and consequently $[a, b, c]$ implies $[c, b, a]$.

Let $[a, b, c]$ and $[b, d, c]$. $[a, b, c]$ and the continuity axiom imply the existence of points A, B, C on rays a, b, c respectively such that $[A, B, C]$, furthermore $[b, d, c]$ and the continuity axiom imply the existence of a point D on d such that $[B, D, C]$. But $[A, B, C]$ and $[B, D, C]$ imply $[A, B, D]$ and the continuity axiom finally gives $[a, b, d]$. This proves part (e).

We shall now give an indirect proof of the last part of the theorem. Let $[a, b, c]$, $[b, c, d]$, and $\sim[a, b, d]$. a, b, d being distinct elements of a half-bundle, part (b) implies that $\sim[a, b, d]$ is equivalent to $[b, d, a]$ or $[d, a, b]$.

If we have $[a, b, c]$, $[b, c, d]$, and $[b, d, a]$ we observe that parts (d) and (e) applied to $[a, b, c]$ and $[b, d, a]$ give $[c, b, d]$ which contradict $[b, c, d]$.

If we have $[a, b, c]$, $[b, c, d]$, and $[d, a, b]$, we observe first that $[b, c, d]$ implies the existence of points B, C, D on rays b, c, d respectively such that $[B, C, D]$. Moreover $[d, a, b]$ implies the existence of a point $A \in a$ such that $[D, A, B]$. But $[B, A, D]$ and $[B, C, D]$ imply $[B, C, A]$ or $[B, A, C]$ and consequently we have $[b, c, a]$ or $[b, a, c]$ which in either case contradict $[a, b, c]$. This completes the proof of Theorem 3.

We shall use from now on the properties of the betweenness relation for the elements of a half-bundle without further reference. In particular we shall use the following ones:

$[a, b, c]$ and $[b, d, c]$ imply $[a, d, c]$;
$[a, b, c]$ and $[a, b, d]$ imply $[a, d, c]$ or $[a, c, d]$, and $[b, c, d]$ or $[b, d, c]$;
$[a, b, c]$ and $[a, d, c]$ imply $[a, b, d]$ or $[a, d, b]$, and $[b, d, c]$ or $[d, b, c]$.

6. Properties of the half-bundles. If HB_{oa} is a half-bundle we shall call *opposite half-bundle* the class of rays x such that the opposite ray $\bar{x}$ is in HB_{oa}. The opposite half-bundle of HB_{oa} is denoted $\overline{HB}_{oa}$. We shall prove in Lemma 4 below that the opposite half-bundle of a half-bundle is itself a half-bundle.

LEMMA 1. *If b is an element of HB_{oa}, then $HB_{ob} = HB_{oa}$.*

Proof. If $b = a$ the lemma is obvious. If $b \neq a$, then $b \in HB_{oa}$ if and only if $[o, a, b]$ or $[o, b, a]$. But as "$[o, a, b]$ or $[o, b, a]$" is a symmetric sentence in a and b, $b \in HB_{oa}$ if and only if $a \in HB_{ob}$, and consequently it is sufficient to prove that $HB_{ob} \subset HB_{oa}$. Let $x \in HB_{ob}$ that is to say let x such that $[o, b, x]$ or $[o, x, b]$ or $x = b$.

Case I: $[o, a, b]$. $[o, a, b]$ and $[o, b, x]$ imply $[o, a, x]$ and $x \in HB_{oa}$. If we have $[o, a, b]$ and $[o, x, b]$ then $[o, a, x]$ or $[o, x, a]$ and again $x \in HB_{oa}$.

Case II: $[o, b, a]$. If $[o, b, a]$ and $[o, b, x]$, then $[o, a, x]$ or $[o, x, a]$and $x \in HB_{oa}$. Furthermore $[o, b, a]$ and $[a, x, b]$ imply $[o, x, a]$ and again $x \in HB_{oa}$.

Finally if $x = b$, then in both cases $x \in HB_{oa}$, and the proof is complete.

LEMMA 2. *On each half-bundle HB_{oa} and to each real number β between* 0 *and* 180 *there is only one ray b such that $\angle ob = \beta$.*

Proof. If b and b' are rays of HB_{oa} such that $\angle ob = \angle ob' = \beta$ then Lemma 1 implies that $HB_{oa} = HB_{ob}$ and consequently we have $[o, b', b]$ or $[o, b, b']$ or $b = b'$. But as $[o, b', b]$ or $[o, b, b']$ imply that $\angle ob' + \angle b'b = \angle ob$ or $\angle ob + \angle bb' = \angle ob'$ respectively, $\angle bb' = 0$, and $b = b'$.

LEMMA 3. *If a, b, c are distinct rays with the same end-point O, then*
(a) $[a, b, c]$ *is equivalent to* $[b, c, \bar{a}]$,
(b) $[a, b, \bar{c}]$ *if and only if* $[a, c, \bar{b}]$,
(c) $[a, \bar{b}, c]$ *is equivalent to* $[a, \bar{c}, b]$,
(d) $[a, \bar{b}, \bar{c}]$ *if and only if* $[\bar{a}, b, c]$.

Proof. $[a, b, c]$ and the continuity axiom imply the existence of points A, B, C on rays a, b, c respectively such that $[A, B, C]$. Let A' be on ray $\bar{a}$ (Fig. 1).

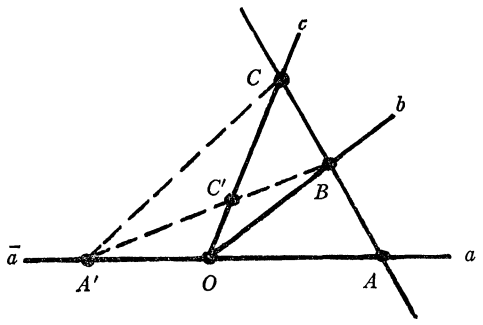

FIG. 1

Then we have $[A', O, A]$ (where O denotes the common end-point of the rays a, b, c) and the continuity axiom applied twice to the rays $A'A$, $A'B$, $A'C$ with end-point A' implies the existence of a point $C' \in c$ such that $[O, C', C]$. Furthermore, $C \notin$ line AA', $[A', O, A]$ imply $[CA', CO, CA]$, and consequently we have $[A', C', B]$. But $[A', C', B]$ implies $[b, c, \bar{a}]$ and the proof that $[a, b, c]$ implies $[b, c, \bar{a}]$ is complete. Five successive applications of this implication to $[b, c, \bar{a}]$ give $[a, b, c]$ and part (a) is proved.

Parts (b), (c), (d) result from part (a) and Theorem 3 part (d).

LEMMA 4. (a) $HB_{\bar{o}a} = HB_{oa}$ *and* $\bar{o} \notin HB_{oa}$,
(b) $HB_{o\bar{a}} = \overline{HB}_{oa}$,
(c) *the opposite half-bundle of a half-bundle is a half-bundle.*

Proof. (a) $x \in HB_{oa}$ if and only if $[o, x, a]$ or $[o, a, x]$ or $x = a$ and $x \in HB_{\bar{o}a}$ if and only if $[\bar{o}, x, a]$ or $[\bar{o}, a, x]$ or $x = a$, but as Lemma 3 implies that $[\bar{o}, x, a]$ and $[o, a, x]$ are equivalent as well as $[\bar{o}, a, x]$ and $[o, x, a]$ are equivalent $HB_{\bar{o}a} = HB_{oa}$. As $\bar{o} \notin HB_{\bar{o}a}$, then $\bar{o} \notin HB_{oa}$.

(b) $x \in HB_{o\bar{a}}$ if and only if $[o, x, \bar{a}]$ or $[o, \bar{a}, x]$ or $x = \bar{a}$, and $x \in \overline{HB}_{oa}$ if and only if $[o, \bar{x}, a]$ or $[o, a, \bar{x}]$ or $\bar{x} = a$. But Lemma 3 implies that $[o, \bar{x}, a]$ and $[o, \bar{a}, x]$ are equivalent; Lemma 3 implies also that $[o, a, \bar{x}]$ and $[o, x, \bar{a}]$ are equivalent. As we know that $\bar{x} = a$ if and only if $x = \bar{a}$, the proof of part (b) is complete.

(c) Part (c) is an immediate consequence of part (b).

We shall call o and $\bar{o}$ the *end-rays* of the half-bundle HB_{oa}.

THEOREM 4. *If x and o are two noncollinear rays with the same end-point, then* $\angle ox + \angle x\bar{o} = 180$.

Proof. Let y be an element of the half-bundle HB_{ox} distinct from x. We have either $[o, x\ y]$ or $[o, y, x]$ and we shall consider first the case $[o, x, y]$. $[o, x, y]$ implies $[x, y, \bar{o}]$ (Lemma 3); thus $\angle ox + \angle xy = \angle oy$ and $\angle xy + \angle y\bar{o} = \angle x\bar{o}$. Consequently $\angle ox + \angle x\bar{o} = \angle oy + \angle y\bar{o}$ and as $[o, y, x]$ leads to the same result we have that in the half-bundle HB_{ox} the sum of the measures of "supplementary" angles with sides o, $\bar{o}$ is a constant $\alpha = \angle ox + \angle x\bar{o}$. We shall now prove that $\alpha = 180$.

Let $\angle ox + \angle x\bar{o} = \alpha < 180$ and let z be an element of HB_{ox} such that $\angle oz = \alpha$ (axiom A_5). Then $\angle oz + \angle z\bar{o} = \alpha$, $\angle z\bar{o} = 0$ and $z \notin HB_{ox}$ which is a contradiction.

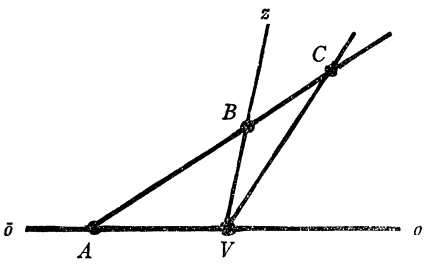

FIG. 2

Let now $\angle ox + \angle x\bar{o} = \alpha = 180 + \beta$ where $\beta > 0$, and let z be an element of HB_{ox} such that $\angle oz = \beta$. Then $\angle oz + \angle z\bar{o} = 180 + \beta$ so that $\angle z\bar{o} = 180$. If A and B are points of rays $\bar{o}$ and z respectively then there exists a point C such that $[A, B, C]$; consequently $[VA, VB, VC]$, where V is the vertex of the half-bundle HB_{ox}, and $\angle \bar{o}z + \angle z$ (ray VC) $= \angle \bar{o}$ (ray VC). But as $\angle \bar{o}z = 180$, $\angle \bar{o}$ (ray VC) > 180 which is a contradiction. This completes the proof of Theorem 4.

7. Bundles of rays. A *bundle* ab, denoted B_{ab}, is the class of rays $HB_{ab} \cup \overline{HB}_{ab} \cup \{a\} \cup \{\bar{a}\}$. We have immediately that $x \in B_{ab}$ if and only if

$$[a, b, x] \text{ or } [a, x, b] \text{ or } [a, b, \bar{x}] \text{ or } [a, \bar{x}, b] \text{ or } x = a \text{ or } \bar{x} = a \text{ or } x = b \text{ or } \bar{x} = b. \tag{1}$$

We shall use the notation $P(a, \bar{a}, b, \bar{b}, x, \bar{x})$ for this last sentence. In the following theorem we shall prove that a bundle is uniquely defined by two noncollinear rays. To simplify the proof we shall first establish four symmetries of the sentence $P(a, \bar{a}, b, \bar{b}, x, \bar{x})$.

LEMMA 5. *The sentence* $P(a, \bar{a}, b, \bar{b}, x, \bar{x})$ *is*: (a) *symmetric in the letters* $a, \bar{a}$, (b) *symmetric in the letters* $b, \bar{b}$, (c) *symmetric in the letters* $x, \bar{x}$, *and* (d) *symmetric in the letters* a, b.

Proof. It is sufficient to prove the symmetries only for the part "$[a, b, x]$ or $[a, x, b]$ or $[a, b, \bar{x}]$ or $[a, \bar{x}, b]$." The symmetry in $x, \bar{x}$ is obvious and, since $[\bar{a}, b, x]$, $[\bar{a}, x, b]$, $[\bar{a}, b, \bar{x}]$, $[\bar{a}, \bar{x}, b]$ are respectively equivalent to $[a, x, b]$, $[a, b, x]$, $[a, \bar{x}, b]$, and $[a, b, \bar{x}]$, we have the symmetry in the letters $a, \bar{a}$.

Furthermore, as $[a, \bar{b}, x]$, $[a, x, \bar{b}]$, $[a, \bar{b}, \bar{x}]$, $[a, \bar{x}, \bar{b}]$ are respectively equivalent to $[a, \bar{x}, b]$, $[a, b, \bar{x}]$, $[a, x, b]$, and $[a, b, x]$, we have the symmetry in the letters $b, \bar{b}$. Finally, as $[b, a, x]$, $[b, x, a]$, $[b, a, \bar{x}]$, $[b, \bar{x}, a]$ are respectively equivalent to $[a, b, \bar{x}]$, $[a, x, b]$, $[a, b, x]$, and $[a, \bar{x}, b]$, we have the symmetry in the letters a, b. All the above equivalences are readily obtained with Lemma 3 and Theorem 3 part (d).

THEOREM 5. *If* x *and* y *are noncollinear elements of a bundle* B_{ab}, *then* $B_{ab} = B_{xy}$.

Proof. With the given hypothesis on the rays a, b, x, y, we have to prove that

$$P(a, \bar{a}, b, \bar{b}, x, \bar{x}) \,\&\, P(a, \bar{a}, b, \bar{b}, y, \bar{y}) \,\&\, P(a, \bar{a}, b, \bar{b}, z, \bar{z}) \Rightarrow P(x, \bar{x}, y, \bar{y}, z, \bar{z})$$

and

$$P(a, \bar{a}, b, \bar{b}, x, \bar{x}) \,\&\, P(a, \bar{a}, b, \bar{b}, y, \bar{y}) \,\&\, P(x, \bar{x}, y, \bar{y}, z, \bar{z}) \Rightarrow P(a, \bar{a}, b, \bar{b}, z, \bar{z}).$$

Using the symmetry of $P(a, \bar{a}, b, \bar{b}, x, \bar{x})$ in the letters $x, \bar{x}$, in the letters $b, \bar{b}$ and in the letters a, b, we can easily show that $P(a, \bar{a}, b, \bar{b}, x, \bar{x})$ reduces to

$$x = a \quad \text{or} \quad [a, b, x]. \tag{2}$$

Using the symmetry in the letters $a, \bar{a}$, and the symmetry in the letters $y, \bar{y}$, we can also show that $P(a, \bar{a}, b, \bar{b}, y, \bar{y})$ reduces to

$$y = a \quad \text{or} \quad y = b \quad \text{or} \quad [a, y, b]. \tag{3}$$

The symmetry in the letters $z, \bar{z}$, implies that the sentences $P(a, \bar{a}, b, \bar{b}, z, \bar{z})$ and $P(x, \bar{x}, y, \bar{y}, z, \bar{z})$ reduce respectively to

$$z = a \quad \text{or} \quad z = b \quad \text{or} \quad [a, b, z] \quad \text{or} \quad [a, z, b], \tag{4}$$

and

(5) $$z = x \quad \text{or} \quad z = y \quad \text{or} \quad [x, y, z] \quad \text{or} \quad [x, z, y].$$

We have then to prove that (2), (3), (4) imply $P(x, \bar{x}, y, \bar{y}, z, \bar{z})$ and conversely that (2), (3), (5) imply $P(a, \bar{a}, b, \bar{b}, z, \bar{z})$. We shall now prove the first of these implications, that is to say, $B_{ab} \subset B_{xy}$.

If z is collinear with a or b then we have the following possible cases ($x = y = a$ should be excluded):

$$x = a \quad \text{and} \quad y = b \quad \text{and,} \quad z = a \quad \text{or} \quad z = b,$$
$$x = a \quad \text{and} \quad [a, y, b] \quad \text{and,} \quad z = a \quad \text{or} \quad z = b,$$
$$[a, b, x] \quad \text{and} \quad y = a \quad \text{and,} \quad z = a \quad \text{or} \quad z = b.$$
$$[a, b, x] \quad \text{and} \quad y = b \quad \text{and,} \quad z = a \quad \text{or} \quad z = b,$$
$$[a, b, x] \quad \text{and} \quad [a, y, b] \quad \text{and,} \quad z = a \quad \text{or} \quad z = b.$$

In the four first cases, we can easily see that $z \in B_{xy}$. In the last case we have $[x, y, z]$ or $[x, z, y]$ and consequently $z \in B_{xy}$.

If z is not collinear with a or b then we have the five following cases ($x = y = a$ should also be excluded):

(6) $$x = a \quad \text{and} \quad y = b \quad \text{and,} \quad [a, b, z] \quad \text{or} \quad [a, z, b],$$

(7) $$x = a \quad \text{and} \quad [a, y, b] \quad \text{and,} \quad [a, b, z] \quad \text{or} \quad [a, z, b],$$

(8) $$[a, b, x] \quad \text{and} \quad y = a \quad \text{and,} \quad [a, b, z] \quad \text{or} \quad [a, z, b]$$

(9) $$[a, b, x] \quad \text{and} \quad y = b \quad \text{and,} \quad [a, b, z] \quad \text{or} \quad [a, z, b],$$

(10) $$[a, b, x] \quad \text{and} \quad [a, y, b] \quad \text{and,} \quad [a, b, z] \quad \text{or} \quad [a, z, b].$$

If $x = a$, $y = b$, and $[a, b, z]$ or $[a, z, b]$, then $[x, y, z]$ or $[x, z, y]$ and $z \in B_{xy}$. If $x = a$, $[a, y, b]$, and $[a, b, z]$ or $[a, z, b]$, then $[x, y, z]$ or $[x, z, y]$ and in each case $z \in B_{xy}$. If $y = a$, $[a, b, x]$, and $[a, b, z]$ or $[a, z, b]$, then we have $[x, y, \bar{z}]$ or $[x, z, y]$ and $z \in B_{xy}$. In case (9), $y = b$, $[a, b, x]$, and $[a, b, z]$ or $[a, z, b]$ imply $[x, y, \bar{z}]$ or $[x, z, y]$ or $[x, y, z]$ and consequently $z \in B_{xy}$.

Finally in case (10): $[a, b, x]$ and $[a, y, b]$ imply $[y, b, x]$; moreover $[a, y, b]$ and $[a, b, z]$ imply $[y, b, z]$; $[y, b, z]$ and $[y, b, x]$ imply $[x, y, \bar{z}]$ or $[x, z, y]$ and $z \in B_{xy}$. Furthermore $[a, b, x]$ and $[a, z, b]$ imply $[z, b, x]$. Then $[y, b, x]$ and $[z, b, x]$ imply $[x, y, z]$ or $[x, z, y]$ and again $z \in B_{xy}$. This completes the proof of $B_{ab} \subset B_{xy}$.

In a very similar way we prove that $B_{xy} \subset B_{ab}$.

8. Triangles, parallel lines, and the concept of plane. A *triangle* is an unordered set of three distinct points; the points are the *vertices* of the triangle. The three closed intervals or segments defined by the vertices of a triangle are the *sides* of the triangle. We shall denote by AB (or BA) the distance between the points A and B of the side AB. The three angles defined by the sides of a triangle are the *angles* of the triangle. In the context of triangles, for instance in a triangle ABC, the measure of an angle, say angle ABC with vertex B, will be

denoted $\angle B$ instead of $\angle ABC$. Two triangles are *similar* if the vertices can be labelled A, B, C and A', B', C' in such a way that

$$AB/A'B' = BC/B'C' = CA/C'A',$$

and $\angle A = \angle A'$, $\angle B = \angle B'$, $\angle C = \angle C'$. A triangle is *proper* if the vertices are noncollinear.

SIMILARITY AXIOM. *If two triangles ABC and $A'B'C'$ are such that $AB/A'B' = BC/B'C'$ and $\angle B = \angle B'$, then they are similar.*

THEOREM 6. *The sum of the measures of the angles of a proper triangle is equal to* 180.

The proof of this theorem can be found in [2]. The following four lemmas correspond to Lemmas 1, 2, 4, and 5 in [2] but the proofs are somewhat different. From now on it will be convenient to use also for the bundles the notation B_0 where the right subscript denotes the vertex of the bundle.

LEMMA 6. *Let l be an element of a bundle B_0 and let α, β be two numbers between* 0 *and* 180. *If m is a ray of B_0 such that $\angle lm = \alpha$, then there exists a ray n of B_0, more precisely of $\overline{HB}_{lm}$, with the following properties*: (a) $\angle ln = \beta$, (b) *for all points $M \in m$ and for all points $N \in n$ the interval MN has a point P in common with the unique line containing the ray l.*

Proof. Let l, m be two rays of B_0 such that $\angle lm = \alpha$. Let n be an element of $\overline{HB}_{lm}$ such that $\angle ln = \beta$. But $n \in \overline{HB}_{lm}$ if and only if $[l, m, \bar{n}]$ or $[l, \bar{n}, m]$ or $\bar{n} = m$ that is to say if and only if $[m, l, n]$ or $[n, \bar{l}, m]$ or $\bar{n} = m$. If $M \in m$ and if $N \in n$, then the continuity axiom implies the existence of a point P such that $P \in l$ or $P \in \bar{l}$ if $[m, l, n]$ or $[n, \bar{l}, m]$; if $\bar{n} = m$ then P is the vertex of the bundle.

Two distinct lines having a point in common determine four angles for which the sides are noncollinear; if those angles have all the same measure then the lines are *perpendicular*. It is easy to show that this common measure is 90.

LEMMA 7. *If l is a line and if P is a point not on the line l, then there exists one and only one line containing P and perpendicular to l.*

Proof. Let A be a point of l, and let h be one of the rays defined by A on l. Furthermore let HB_{ha} (where a denotes the ray AP) be the half-bundle defined by h and a (Fig. 3). If b is a ray of $\overline{HB}_{ha}$ such that $\angle bh = \angle ha$, and if P' is the point of ray b such that $AP' = AP$ then Lemma 6 implies that the interval PP' has a point I in common with the line l. If $I = A$ the points P, A, and P' belong to a line and this line is perpendicular to l. If $I \neq A$, the similarity axiom together with Theorem 4 imply that the triangles PAI and $P'AI$ are similar and $\angle AIP = \angle AIP' = 90$ and PI is a line perpendicular to l. If there exists another perpendicular PI' from P to l, then the triangle PII' is a proper triangle with two angles with measure 90 which is a contradiction.

The set consisting of the points belonging to the rays of a bundle B_o and the point O (vertex of B_o), denoted $\{B_o\}$, is called a *plane*. Any ray a of B_o deter-

mines exactly two half-bundles, one of them containing a ray b of B_o and the other one containing the ray $\bar{b}$. The set of points belonging to the rays of a half-bundle HB_{ab}, denoted $\{HB_{ab}\}$, is called a *half-plane.*

THEOREM 7. *If M and N are two distinct points of a plane $\{B_o\}$ then the line MN belongs to the plane $\{B_o\}$.*

Proof. The theorem is obvious if M, N, and the vertex O of B_o are collinear. If m, n are the noncollinear rays of B_o such that $M \in m$, $N \in n$, then X is a point of the line MN distinct from M and distinct from N if and only if $[X, M, N]$ or $[M, X, N]$ or $[M, N, X]$. Consequently the continuity axiom implies $[x, m, n]$ or $[m, x, n]$ or $[m, n, x]$ where x denotes the ray OX, and then, as $[x, m, n]$ is equivalent to $[m\ n, \bar{x}]$, x is an element of either HB_{mn} or $\overline{HB}_{mn}$. Finally Theorem 5 implies that $x \in B_o$ and $X \in \{B_o\}$.

LEMMA 8. *If two bundles B_o and $B_{o'}$ with vertices O and O' are such that $O \neq O'$, if there exists a point A such that A is not collinear with the points O, O', and if A, O, O' belong to $\{B_o\}$ and to $\{B_{o'}\}$, then the planes $\{B_o\}$ and $\{B_{o'}\}$ coincide.*

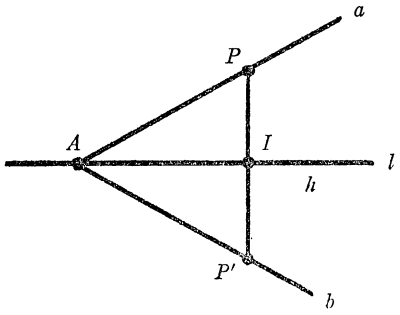

FIG. 3

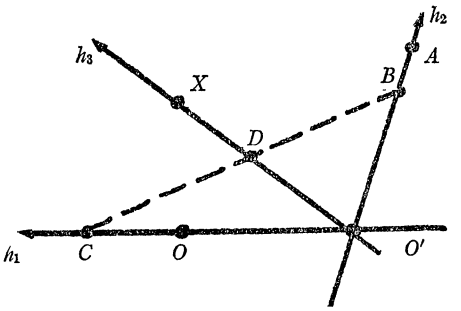

FIG. 4

Proof. Let h_1 and h_2 denote the rays $O'O$ and $O'A$ respectively (Fig. 4). If X is a point of the plane $\{B_{o'}\}$ we shall denote h_3 the ray $O'X$. With those notations, X belongs to the plane $\{B_{o'}\}$ if and only if $[h_1, h_2, h_3]$ or $[h_1, h_3, h_2]$ or $[h_1, h_2, \bar{h}_3]$ or $[h_1, \bar{h}_3, h_2]$ or $h_3 = h_1$ or $\bar{h}_3 = h_1$ or $h_3 = h_2$ or $\bar{h}_3 = h_2$. If h_3 or $\bar{h}_3$ coincides with h_1 then $X \in \{B_o\}$. If h_3 or $\bar{h}_3$ coincides with h_2 then as A and O' are in $\{B_o\}$, Theorem 7 implies that X is an element of $\{B_o\}$. In the cases $[h_1, h_3, h_2]$ or $[h_1, \bar{h}_3, h_2]$, if $B \in h_2$ and if $C \in h_1$ then the continuity axiom implies the existence of a point D on h_3 or on $\bar{h}_3$ such that $[B, D, C]$. In the cases $[h_1, h_2, h_3]$ or $[h_1, h_2, \bar{h}_3]$ then we have $[h_2, h_3, \bar{h}_1]$ or $[h_2, \bar{h}_3, \bar{h}_1]$ and if $B \in h_2$, $C \in \bar{h}_1$, then the continuity axiom implies the existence of a point D on h_3 or on $\bar{h}_3$ such that $[B, D, C]$. A and O' being in the plane $\{B_o\}$, B also belongs to the plane $\{B_o\}$. In the same way B and C being in $\{B_o\}$, D is in $\{B_o\}$. Finally D and O' being in $\{B_o\}$, X belongs to $\{B_o\}$ and $\{B_{o'}\} \subset \{B_o\}$. In the same way $\{B_o\} \subset \{B_{o'}\}$ and the proof is complete.

If two lines of a plane coincide or have no point in common, then they are *parallel.*

LEMMA 9. *If B_o is a bundle, if l is a line defined by a ray h of B_o, and if P is a point of the plane $\{B_o\}$ not on l, then there exists one and only one line in the plane $\{B_o\}$ containing P and parallel to l.*

Proof. Lemma 7 implies the existence of a unique perpendicular PD from P to l. P and D being distinct elements of $\{B_o\}$, the perpendicular PD is in the plane $\{B_o\}$. If $D \neq O$ then there exists in the plane $\{B_{PD,PO}\}$ a unique perpendicular m from P to the line PD. But Lemma 8 implies that $\{B_o\} = \{B_{PD,PO}\}$ and $m \subset \{B_o\}$. m is parallel to l for, if T is on m and on l, then we would have from T two distinct perpendiculars to the line PD.

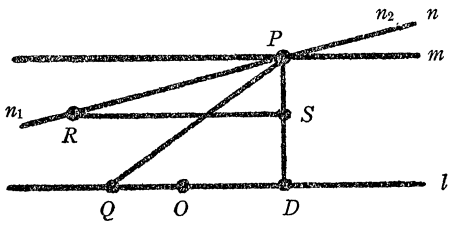

FIG. 5

If n is another parallel from P to l in the plane $\{B_o\}$, then $n \subset \{B_{PD,PO}\}$ and we can distinguish on n two opposite rays n_1, n_2 with end-point P in $B_{PD,PO}$; one of those rays, say n_1, is in $HB_{PD,PO}$ and the other one is in $\overline{HB}_{PD,PO}$. We have then either $\angle(\text{ray } PD)\ (n_1) < 90$ or $\angle(\text{ray } PD)\ (n_1) > 90$.

Case 1: $\angle(\text{ray } PD)\ (n_1) < 90$. Let R be a point of n_1 and let RS be the unique perpendicular from R to the line PD. Then S is a point of the ray PD (otherwise the sum of the measures of the angles of the triangle PSR would be greater than 180). If Q is a point of the ray DO such that $DQ = (PD \cdot RS)/PS$, then the similarity axiom implies that the triangles PSR and PDQ are similar and consequently that $\angle DPR = \angle DPQ$. But $Q \in$ ray DO if and only if $Q = O$ or $[D, O, Q]$ or $[D, Q, O]$, and as $[D, O, Q]$ or $[D, Q, O]$ imply $[PD, PO, PQ]$ or $[PD, PQ, PO]$, in each case ray PQ belongs to $HB_{PD,PO}$. Consequently Lemma 2 implies that ray PR and ray PQ coincide, and we have from Q two perpendiculars to the line PD which is a contradiction.

Case 2: $\angle(\text{ray } PD)\ (n_1) > 90$. In that case $\angle(\text{ray } PD)\ (n_2) < 90$ and using the preceding argument in the half-bundle $\overline{HB}_{PD,PO}$ (containing the ray n_2) with the ray DO we obtain also a contradiction and consequently m is the unique parallel from P to l in $\{B_o\}$.

If D coincides with O then the same argument applies by choosing a point $O' \neq O$ on the line l.

THEOREM 8. *Two planes coincide if and only if they have three noncollinear points in common.*

The proof of this theorem can be found in [2]. The results of lemmas 7 and 9 can be formulated in a more general form as follow.

THEOREM 9. *In a plane, from a given point there exists one and only one perpendicular to a given line, and from a given point there exists one and only one parallel to that line.*

The following theorem is an immediate consequence of the continuity axiom.

THEOREM 10. *If three distinct points A, B, and C do not lie on the same line, and if D and E are two points such that C is between B and D, and E is between A and C, then there exists between A and B a point F such that D, E, F lie on the same line.*

9. 3-dimensional euclidean space. The following axiom is now added to the structure.

S. *There exists a point not on a given plane.*

The 3-dimensional euclidean space is introduced as defined by O. Veblen in [5]. A set of four noncoplanar points is called a *tetrahedron* whose *faces* are the interior of the triangles defined by the elements of the tetrahedron (the interior of a proper triangle ABC is defined to be the class of points P between X and Y, where X and Y belong to different intervals defined by the points A, B, and C). A *3-space* $ABCD$ is the set of all points collinear with any two points of the faces of the tetrahedron $ABCD$.

Except for the Axiom X, the remaining eleven axioms given in [5] are either a property of real numbers, a consequence of a definition given here, or one element of the following list of axioms and theorems: E_1, E_3, E_4, D_4, S, Theorem 2, Theorem 9, and Theorem 10. The Axiom X says that all points belong to the same 3-space. We have then in [5] the proof of the following property concerning categoricity.

THEOREM 11. *If M_1 and M_2 are two models of a given 3-space, then they are isomorphic.*

RODRIGUES FORMULA SOLUTIONS TO SOME SECOND ORDER DIFFERENTIAL EQUATIONS

J. M. HORNER, General Motors Research Laboratories, Warren, Michigan
(Now at the University of Alabama in Huntsville)

In the following paragraphs we continue our investigation (see [3], [4]) of the second order differential equation (DE)

$$p_2(x)y'' + p_1(x)y' + a_0y = q(x), \tag{1}$$

where

$$\begin{cases} p_2(x) = a_2x^2 + b_2x + c_2 \not\equiv 0 \\ p_1(x) = a_1x + b_1 \\ |a_2| + |a_1| \neq 0 \end{cases} \tag{2}$$

and a_2, b_2, c_2, a_1, b_1, and a_0 are constants.

Among the special cases of (1) are the Legendre equation, the hypergeometric equation, the confluent hypergeometric equation, the Gegenbauer equation, the Jacobi equation, the Hermite equation, the two Tchebicheff equations, the equations of the Laguerre and Sonine polynomials, and, by well-known transformations, the Bessel equation and numerous other classical equations (see [5] and [7]).

For convenience, let

$$g(j, x) = p_2^j \exp\left[-\int (p_1/p_2)dx\right]. \tag{3}$$

Unless otherwise stated, x is a real variable and j in (3) is an integer. $g(0, x)$ is of course a constant multiple of the Wronskian of any fundamental system for (1) [8, pp. 117–119]. The integration constant in (3) is arbitrary so that the indefinite integral may be replaced by a definite integral.

In [2], [3], and [4] we defined the *associated equation* of the DE (1) to be the quadratic equation

$$A(t) = a_2t^2 + (a_2 - a_1)t + a_0 = 0 \tag{4}$$

and frequently encountered the first order DE

$$p_2v' + (p_1 - up_2')v = h(x). \tag{5}$$

In order to avoid repetitious hypotheses, j, k, n, and p will always be used to represent nonnegative integers.

One of the principal results of [2] and [4] is that when $A(n)=0$, $n>0$, and $q(x)\equiv 0$, the DE (1) has the $n+1$ solutions

$$y_1(x) = D^{n-1}[g(n, x)] \tag{6}$$

and

$$y_j(x) = D^{n-1}\left\{g(n,x)\int [x^{j-2}/g(n+1,x)]dx\right\}, \tag{7}$$

where $D \equiv d/dx$, $2 \leqq j \leqq n+1$, and the integration constants are arbitrary.

The primary purposes of the present paper are to extend these results by a transformation and to answer the question of if and when this set of solutions contains a fundamental system, i.e., a pair of nontrivial linearly independent solutions.

One might question the importance of studying (1) for the special case in which $A(t)=0$ has positive integral roots. Actually, this is an extremely important case. A few well-known equations which have integral associated roots are the differential equations for the Legendre, Sonine, Tchebicheff, Jacobi, Hermite, Gegenbauer and hypergeometric polynomials, and, by elementary transformations, the equations of the associated Legendre polynomials and spherical Bessel functions [7].

We will show that the following result is true:

THEOREM 1. *Let* $q(x) \equiv 0$, $n>0$, *and* $A(n)=0$ *so that* (1) *has the solutions* $\{y_j(x): 1 \leqq j \leqq n+1\}$ *of* (6) *and* (7). *Then*:

1. y_1 *and* y_2 *constitute a fundamental system for* (1) *if and only if* n *is the smallest positive integral root of* $A(t)=0$.

2. *If* n *and* k, $k<n$, *are positive integral roots of* $A(t)=0$, *then* y_i *and* y_{n-k+2} *form a fundamental system for* (1), *where* y_i *is a nontrivial choice of* y_1 *or* y_2. *This choice is always possible.*

The proof of this result will be given in several steps.

LEMMA 1. *If, in* (5), $h(x)$ *is a polynomial of degree* $\leqq j$, $v(x)$ *is a polynomial of exact degree* j *and* $A(u)=0$, *then also* $A(u-j-1)=0$.

Proof. Under the assumed conditions, differentiation of (5) $j+1$ times yields

$$(j+1)[p_1' - (u - \tfrac{1}{2}j)p_2'']v^{(j)} = 0.$$

Since $j+1 \neq 0$ and $v^{(j)} \neq 0$, then $a_1 = a_2(2u-j)$. Since we have assumed that $|a_1| + |a_2| \neq 0$, $a_2 \neq 0$. Also, $A(u) = a_2u^2 + (a_2-a_1)u + a_0 = 0$. Combination of these two results gives $a_0 = a_2u(u-j-1)$. Thus, a_1 and a_0 are expressed in terms of a_2, u and j and $A(t)$ becomes $A(t) = a_2(t-u)(t-u+j+1)$.

LEMMA 2. *If* (1) *has a polynomial solution of exact degree* j *and* $q(x) \equiv 0$, *or is a polynomial of degree* $\leqq j-1$, *then* $A(-j)=0$.

Proof. Under the assumed conditions, differentiation of (1) j times gives $[a_2j(j-1)+a_1j+a_0]y^{(j)}=0$. Since $y^{(j)} \neq 0$, then $A(-j)=0$.

We are now in a position to prove part 1 of Theorem 1.

LEMMA 3. *If* $q(x) \equiv 0$ *and* n *is the smallest positive integral root of* $A(t)=0$, *then* y_1 *and* y_2 *form a fundamental system for* (1).

Proof. If $n=1$, the conclusion is evident so suppose that $n\geqq 2$.

If $y_1(x)\equiv 0$, then $g(n, x)$ is a polynomial of exact degree $k\leqq n-2$ and satisfies (5) when $u=n$ and $h(x)\equiv 0$. But then, by Lemma 1, $A(n-k-1)=0$. Since $0\leqq k\leqq n-2$, $n>n-1\geqq n-k-1\geqq 1$ and $n-k-1$ is a positive integral root of $A(t)=0$ which is smaller than n. Thus, $y_1(x)\not\equiv 0$.

If $n\geqq 2$ and $y_2(x)\equiv 0$, then $g(n, x)\int[1/g(n+1, x)]dx$ is a polynomial of exact degree $k\leqq n-2$ and satisfies (5) when $u=n$ and $h(x)\equiv 1$. As before, this implies that $1\leqq n-k-1<n$ and $A(n-k-1)=0$ so $y_2(x)\not\equiv 0$.

Finally, suppose that $K_1y_1(x)+K_2y_2(x)\equiv 0$ for nonzero constants K_1 and K_2. Then

$$v(x) = g(n, x)\left\{K_1 + \int [K_2/g(n+1, x)]dx\right\}$$

is a polynomial of exact degree $k\leqq n-2$ which satisfies (5) when $u=n$ and $h(x)\equiv K_2$. Again this leads to a contradiction of the assumption that n is the smallest positive integral root of $A(t)=0$ and completes the proof.

So long as the integration constants remain arbitrary in (7), it is easy to find DE's for which y_1 and y_2 are the only nontrivial solutions in the set given by (6) and (7).

Example 1. For the DE $x^2y''+4xy'-4y=0$, the associated roots are $t=4$ and $t=-1$. Corresponding to the root $t=4$, the five solutions of (6) and (7) are $y_1(x)=D^3(x^4)=24x$, $y_2(x)=D^3[x^4\int x^{-6}dx]=6x^{-4}/5$ and, for $j=3$, 4, 5, $y_j(x)=D^3[x^4\int x^{j-8}dx]=0$ when the integration constants are taken to be zero.

LEMMA 4. *Let* $A(n)=A(k)=0$, $n>k\geqq 1$, *and let* $\{y_j\colon 1\leqq j\leqq n+1\}$ *and* $\{y_j^*\colon 1\leqq j\leqq k+1\}$ *be the solutions of* (6) *and* (7) *corresponding respectively to* n *and* k. *Then there exist constants* K_p, $1\leqq p\leqq n+1$, *such that*

$$y_p = K_py_1^*, \qquad 1\leqq p\leqq n-k+1 \tag{8}$$

and, for any p *such that* $n-k+2\leqq p\leqq n+1$,

$$y_p = K_py_1^* + \binom{p-2}{n-k}(n-k)!\,y_{p-n+k}^*. \tag{9}$$

Proof. For each y_j in (6) or (7), let v_j be the corresponding right member before application of the operator D^{n-1} and let v_j^* have the same relation to y_j^*.

If $1\leqq p\leqq n-k+1$, v_p satisfies (5) when $u=n$, and $h(x)\equiv 0$ if $p=1$ or $h(x)=x^{p-2}$ if $p\geqq 2$. If $p\geqq 2$, then $0\leqq p-2\leqq n-k-1$ so that in either case differentiation of (5) $n-k$ times yields

$$p_2v_p^{(n-k+1)} + (p_1 - kp_2')v_p^{(n-k)} + (n-k)[a_1 - (n+k+1)a_2]v_p^{(n-k-1)} = 0.$$

Now, $A(n)=A(k)=0$ so

$$a_2k^2 + (a_2 - a_1)k = -a_0 = a_2n^2 + (a_2 - a_1)n$$

and $(n-k)[a_1-(n+k+1)a_2]=0$. Hence, $D^{n-k}(v_p)$ satisfies (5), when $u=k$ and

$h(x) \equiv 0$, and there exist constants K_p such that $D^{n-k}(v_p) = K_p v_1^*$. Differentiation of this result $k-1$ times gives (8).

If $n-k+2 \leqq p \leqq n+1$, v_p satisfies (5) when $u=n$ and $h(x) = x^{p-2}$. Duplication of the above argument shows that $D^{n-k}(v_p)$ satisfies (5) when $u=k$ and

$$h(x) = \binom{p-2}{n-k}(n-k)!\, x^{p-n+k-2}.$$

So, for some constants K_p,

$$D^{n-k}(v_p) = K_p v_1^* + \binom{p-2}{n-k}(n-k)!\, v_{p-n+k}^*$$

and (9) follows by differentiating this result $k-1$ times.

COROLLARY. *If n is the larger of two positive integral roots n and k of $A(t)=0$ and $q(x) \equiv 0$, then no pair of the solutions $y_1, y_2, \cdots, y_{n-k+1}$, corresponding to the root $t=n$, constitute a fundamental system for* (1).

Proof. This result is immediate from (8) and, with Lemma 3, proves the first conclusion of Theorem 1.

It is possible, however, to select from among the set of solutions given by (6) and (7) a fundamental system for (1) when $q(x) \equiv 0$ and n is the larger of two positive integral roots of $A(t)=0$.

LEMMA 5. *Let $q(x) \equiv 0$, $A(n) = A(k) = 0$, $n > k > 0$ and $\{y_j\colon 1 \leqq j \leqq n+1\}$ be the solutions of* (6) *and* (7) *corresponding to the root n. Then y_{n-k+2} and one of y_1 and y_2 form a fundamental system for* (1).

Proof. With the notation of Theorem 2, it follows from Theorem 1 that y_1^* and y_2^* form a fundamental system for (1) when $q(x) \equiv 0$.

It is then evident from (8) and (9) that if there exists among the solutions $y_1, y_2, \cdots, y_{n-k+1}$ one which is nontrivial, then this solution and y_{n-k+2} constitute a fundamental system for (1) when $q(x) \equiv 0$. We will show that $y_1 \not\equiv 0$ when $k=n-1$ and $p_1 \not\equiv np_2'$, that $y_2 \not\equiv 0$ when $k=n-1$ and $p_1 \equiv np_2'$, and that y_1 and y_2 are not both trivial when $k \neq n-1$.

Suppose first that $k=n-1$. Then, as in the proof of Lemma 4, $a_1 = 2na_2$ and $p_1 - np_2' = K$ for some constant K. If $p_1 \equiv np_2'$, then $K=0$ and y_2 is equivalent to

$$D^{n-1}\left[\int p_2^{-1}dx\right] = D^{n-2}(p_2^{-1}) \not\equiv 0.$$

If $p_1 \not\equiv np_2'$, then $K \neq 0$ and y_1 is equivalent to

$$D^{n-1}\left[\exp\left(-\int Kp_2^{-1}dx\right)\right] \not\equiv 0.$$

Thus $y_1 \not\equiv 0$ when $k = n-1$ and $p_1 \not\equiv np_2'$, and $y_2 \not\equiv 0$ when $k = n-1$ and $p_1 = np_2'$.

Now suppose that $k \neq n-1$ and assume that $y_2 \equiv 0$. Then, from (8), $K_2 = 0$ since $y_1^* \not\equiv 0$. But in the proof of Lemma 4 it was shown that $D^{n-k}(v_2) = K_2 v_1^*$. Thus v_2 is a polynomial of exact degree $j \leqq n-k-1$ which satisfies (5) when $u = n$ and $h(x) \equiv 1$. But then $h(x)$ has degree $\leqq j$ and $A(n) = 0$, so Lemma 1 shows that also $A(n-j-1) = 0$. However $A(t)$ has only the two zeroes $t = n$ and $t = k$. So $j = n-k-1$ and v_2 has exact degree $n-k-1$. Similarly, if $y_1 \equiv 0$ then v_1 is a polynomial of exact degree $n-k-1$. So, if both y_1 and y_2 are trivial and $k \neq n-1$, then both v_1 and v_2 are polynomials of exact degree $n-k-1$. But, from (6) and (7) it is seen that $v_2 = Kv_1 \int (p_2 v_1)^{-1} dx$, where K is a nonzero constant. But this implies that $\int (p_2 v_1)^{-1} dx$ is constant, which is clearly false. Thus, y_1 and y_2 are not both trivial when $k \neq n-1$. Since y_2, for an appropriate choice of the integration constant, contains a multiple of y_1, a fundamental system can always be obtained from y_{n-k+2} and y_2 by a proper choice of the constant.

This gives the second conclusion of Theorem 1 which has now been completely proved.

We will now show by examples that without additional hypotheses, the various cases which arose in the proof of the previous lemma can produce the only fundamental system for (1) when $q(x) \equiv 0$.

Example 2. ($k \neq n-1$, $y_1 \equiv 0$),

$$x^2 y'' + 5xy' + 3y = 0.$$

For this Euler DE the associated roots are $t = 1$ and $t = 3$. When $x > 0$, the larger root gives the solutions

$$y_1 = D^2(x) = 0, \qquad y_2 = D^2\left(x \int x^{-3} dx\right) = -x^{-3},$$

$$y_3 = D^2\left(x \int x^{-2} dx\right) = 0 \quad \text{and} \quad y_4 = D^2\left(x \int x^{-1} dx\right) = x^{-1}.$$

The smaller root gives the solutions $y_1^* = x^{-3}$ and $y_2^* = x^{-3} \int x dx = x^{-1}/2$.

Example 3. ($k \neq n-1$, $y_2 \equiv 0$),

$$(x^2 + 1)y'' + 5xy' + 3y = 0.$$

For this DE the associated roots are $t = 1$ and $t = 3$. The larger root gives the solutions

$$y_1 = D^2[(x^2 + 1)^{1/2}],$$

$$y_2 = D^2\left[(x^2 + 1)^{1/2} \int (x^2 + 1)^{-3/2} dx\right]$$

$$= D^2\left\{(x^2+1)^{1/2}\int D[x(x^2+1)^{-1/2}]dx\right\} = 0,$$

$$y_3 = D^2\left[(x^2+1)^{1/2}\int x(x^2+1)^{-3/2}dx\right] = 0,$$

and

$$y_4 = D^2\left[(x^2+1)^{1/2}\int x^2(x^2+1)^{-3/2}dx\right].$$

The smaller root gives the two solutions $y_1^* = (x^2+1)^{-3/2}$ and

$$y_2^* = (x^2+1)^{-3/2}\int (x^2+1)^{-1/2}dx = (x^2+1)^{-3/2}\sinh^{-1} x.$$

This example illustrates an important property of the method described. In many cases solutions are obtained in closed form which would be extremely difficult to recognize from the Frobenius series and which are valid in a larger region than the series solution.

Example 4. ($k=n-1$, $p_1 \not\equiv np_2'$),

$$x(x-1)y'' + (4x-1)y' + 2y = 0.$$

For this DE the associated equation has the roots $t=1$ and $t=2$, and $p_1 - np_2' \equiv 1$. When $0<x<1$, we obtain, for the larger root $t=n=2$, $y_1 = D[x(1-x)^{-1}] = (1-x)^{-2}$,

$$y_2 = D\left[x(1-x)^{-1}\int (-x^{-2})dx = D\left\{x(1-x)^{-1}\int D[(1-x)x^{-1}]dx\right\} = 0,\right.$$

and

$$y_3 = D\left[x(1-x)^{-1}\int (-x^{-1})dx\right] = D[(-x\ln x)(1-x)^{-1}]$$

$$= (x-1-\ln x)(1-x)^{-2}$$

and for the smaller root $t=k=1$, $y_1^* = -(1-x)^{-2}$ and

$$y_2^* = (1-x)^{-2}\int (1-x)x^{-1}dx = -(x-\ln x)(1-x)^{-2}.$$

This example also illustrates an important property of this method. In many elementary DE's having logarithmic Frobenius solutions, which are very tedious to obtain, these solutions are obtained with relative ease by the above procedure.

Example 5. ($k=n-1$, $p_1 = np_2'$),

$$x(x+1)y'' + (4x+2)y' + 2y = 0.$$

For this DE the associated roots are $t=1$ and $t=2$, and $p_1 = 2p_2'$. For $x>0$, the larger root $t=n=2$ yields the solutions $y_1 = D(1) = 0$,

$$y_2 = D\left[\int x^{-1}(x+1)^{-1}dx\right] = x^{-1}(x+1)^{-1}$$

and

$$y_3 = D\left[\int (x+1)^{-1}dx\right] = (x+1)^{-1}$$

while the smaller root $t=k=1$ gives the solutions $y_1^*=x^{-1}(x+1)^{-1}$ and $y_2^* = (x+1)^{-1}$.

Mambriani [9, pp. 38–39] obtained the two solutions y_1 and y_2, given in (6) and (7), for the case that $n \geqq 2$. His method was considerably different however, and the exact relation between n and the coefficients in (1) was apparently not noticed. Using operator methods he "concludes that the general integral of

$$p_2y'' + p_1y' - n[a_2(n+1) - a_1]y = 0$$

is given by $y=K_1y_1+K_2y_2$ where K_1, K_2 are arbitrary constants" (notation of and translation by the present author). As we have seen, this conclusion can be false and, in fact, is always false unless n is the smallest positive integral root of $A(t)=0$.

In the remaining paragraphs we will consider a transformation of (1) into another DE of the same type which has the attractive feature of reversing the role of positive and nonpositive associated roots.

THEOREM 2. *Let $q_1(x)=a_2x+b_0$ and let $v(x)$ be a nontrivial solution to $p_2v' = q_1v$. If there exists a constant c_0 such that*

$$q_1^2 + q_1(p_1 - p_2') + q_1'p_2 = c_0p_2$$

then $y(x)$ is a solution to (1) *if and only if $w(x)=y(x)/v(x)$ is a solution to*

$$p_2w'' + (p_1 + 2q_1)w' + (a_0 + c_0)w = q(x)/v(x).$$

Proof. The proof consists of elementary computation, using the relation $p_2v'=q_1v$ to eliminate terms involving v' and v''.

COROLLARY. *$y(x)$ is a solution to* (1) *if and only if $w(x)=y(x)/g(1, x)$ is a solution to*

$$p_2w'' + (2p_2' - p_1)w' + (2a_2 - a_1 + a_0)w = q(x)/g(1, x) \tag{10}$$

whose associated equation is

$$A^*(t) = a_2t^2 + (a_1 - 3a_2)t + (2a_2 - a_1 + a_0) = 0$$

and $A(r)=0$ if and only if $A^*(1-r)=0$.

Proof. The first part of this result is a special case of Theorem 2, while the second part is quite easily verified. We note also that, when $q(x)\equiv 0$, (10) is the adjoint of (1).

This result, along with Theorem 1, leads to the following companion to Theorem 1.

THEOREM 3. *Suppose that* $q(x)\equiv 0$, $n\geqq 0$ *and* $A(-n)=0$.

1. *The* DE (1) *is satisfied by the* $n+2$ *functions*

$$y_1 = g(1, x)D^n\{[g(1-n, x)]^{-1}\}$$

and, for $2\leqq j\leqq n+2$, $y_j=g(1, x)D^n\{[g(1-n, x)]^{-1}\int x^{j-2}g(-n, x)dx\}$.

2. y_1 *and* y_2 *constitute a fundamental system for* (1) *if and only if* n *is the smallest nonnegative integer such that* $A(-n)=0$.

3. *If* n *and* k, $k<n$, *are nonnegative integers such that* $A(-n)=A(-k)=0$, *then* y_i *and* y_{n-k+2} *form a fundamental system for* (1), *where* y_i *is a nontrivial choice of* y_1 *or* y_2. *This choice is always possible.*

Proof. In Theorem 1, replace n by $n+1$, k by $k+1$ and let the function $g(j, x)$ which corresponds to (10) be denoted by $g^*(j, x)$. Also, let the coefficient of w' in (10) be denoted by p_1^*. Then Theorem 1 applied to (10) becomes: *Let* $q(x)/g(1, x)\equiv 0$ *and* $n+1$ *be a positive integer such that* $A^*(n+1)=0$. *Then* (10) *is satisfied by the* $n+2$ *functions* $w_1=D^n[g^*(n+1, x)]$ *and*

$$w_j = D^n\left\{g^*(n+1, x)\int x^{j-2}[g^*(n+2, x)]^{-1}dx\right\},$$

where $2\leqq j\leqq n+2$. w_1 *and* w_2 *form a fundamental system for* (10) *if and only if* $n+1$ *is the smallest positive integral root of* $A^*(t)=0$. *If* $k+1$ *and* $n+1$, $k+1<n+1$, *are positive integral roots of* $A^*(t)=0$, *then* w_i *and* w_{n-k+2} *form a fundamental system for* (10), *where* $i=0$ *or* $i=2$.

In this case $p_1^*=2p_2'$ and $g^*(j, x)$ is a constant multiple of $[g(2-j, x)]^{-1}$ (they satisfy the same first order DE). The desired result then follows from the previous corollary.

Numerous special cases of the solutions y_1 of Theorem 1 and y_1 of Theorem 3 are well known, but the only systematic method (known to the author) of obtaining solutions of this form is given by Bateman [1, pp. 110–115]. He observed that $y=(x-a)^v(x-b)^u$ satisfied the DE

$$(x-a)(x-b)y'' - [(v-1)(x-b) + (u-1)(x-a)]y' - (u+v)y = 0$$

and, by differentiating this equation n times, obtained

$$(x-a)(x-b)y^{(n+2)} - [(v-n-1)(x-b) + (u-n-1)(x-a)]y^{(n+1)} + [n^2 - n(v+u-1) - u - v]y^{(n)} = 0.$$

By choosing appropriate values of the parameters a, b, v, u, and n, Bateman obtained the solutions corresponding to y_1 of Theorem 1 for several classical equations although he concentrated his attention on the hypergeometric equation. By following this procedure with a transformation, Bateman obtained the solution y_1 of Theorem 3 for a certain subclass of the DE's of the form (1).

The corollary to Theorem 2, along with [4, Theorems 2 and 3], provides the following results:

THEOREM 4. *If* $n \geqq 0$ *and* $A(-n) = 0$, *then a particular solution to* (1) *is*

$$y(x) = g(1, x)D^n\left\{g(1-n, x)\int g(-n, x)D^{-n-1}[q(x)/g(1, x)]dx\right\},$$

where $D^{-k}(f(x)) = \int\int \cdots \int f(x)(dx)^k$.

Proof. This result is obtained from [4, Theorem 2], just as Theorem 3 is obtained from Theorem 1, by making use of the corollary to Theorem 2. As in [4, Theorem 2], it is often convenient to replace $D^{-n-1}[q(x)/g(1, x)]$ by the integral

$$I_{n+1}(x) = (1/n!)\int_a^x [(x-v)^n q(v)/g(1, v)]dv,$$

where the point a need only be a point for which the integral exists and satisfies $D^{n+1}(I_{n+1}(x)) = q(x)/g(1, x)$.

THEOREM 5. *If* $n > 0$, $A(n) = 0$ *and* $q(x)$ *is of class* C^{n-1}, *then every solution to* (1) *has the property that, for some constant* K.

$$D^n[y(x)/g(1, x)] = [g(n+1, x)]^{-1}\left\{K + \int g(n, x)D^{n-1}[q(x)/g(1, x)]dx\right\}.$$

Proof. [4, Theorem 3], and the corollary to Theorem 2 above.

In [5], these results are extended to the case of nonintegral associated roots, using both series and contour integral generalizations, and the entire collection of results is then extended to the general Pochhammer DE.

CONULL AND OTHER MATRICES WHICH SUM A BOUNDED DIVERGENT SEQUENCE

ROBERT WHITLEY, University of Maryland

We generalize a theorem due to Wilansky [6, Theorem 3, page 243]. Our proof is straightforward and we obtain as a corollary the result that there is no matrix isomorphism of c onto c_0; a recent problem in this MONTHLY failed to elicit a simple proof of this [1]. We also point out the relation between our result and Berg's [2] characterization of those conservative matrices which sum a bounded divergent sequence.

The Banach space of bounded scalar sequences (a_n) with sup norm $\|(a_n)\| = \sup |a_n|$ is denoted by m, the closed subspace of sequences converging (to zero) by c (c_0), and the Banach space of sequences (a_n) with finite norm $\|(a_n)\| = \sum |a_n|$ by l.

A conservative matrix is an infinite matrix of scalars (b_{ij}), $i, j = 1, 2, \cdots$, which maps c into c by taking (a_i) into $(\sum_{j=1}^{\infty} b_{ij}a_j)$. The classical Silverman-Toeplitz conditions [7, page 4 and page 118] show that the conservative matrices (b_{ij}) are exactly those satisfying the conditions:

(1) $\sup_n \sum_{k=1}^{\infty} |b_{nk}|$ is finite and

(2) the limits $b_{0k} \equiv \lim_n b_{nk}$, $k = 1, 2 \cdots$ and $b_{00} \equiv \lim_n \sum_{k=1}^{\infty} b_{nk}$ exist.

Recall that each continuous linear functional x' on c corresponds to an element (c_i) in l where for every (a_i) in c we have $x'(a_i) = c_1 \lim a_i + \sum_{i=1}^{\infty} a_i c_{i+1}$ and $\|x'\| = \sum |c_i|$ [7, page 92]. It follows that a conservative matrix T has the form $Tx = (x_n'(x))$, for all x in c, where x_n' is the functional on c which corresponds as above to the sequence $(0, b_{n1}, b_{n2}, \cdots)$ in l. It is easy to see that T is a continuous linear operator mapping c into c with $\|T\| = \sup \|x_n'\| = \sup_n \sum_{k=1}^{\infty} |b_{nk}|$. For a conservative matrix (b_{ij}) we have defined the scalars b_{0n}, $n = 0, 1, \cdots$, in condition (2) of the Silverman-Toeplitz conditions and from condition (1) it follows that the sequence $(b_{00}, b_{01}, b_{02}, \cdots)$ is in l. Let x_0' be the continuous linear functional on c which corresponds to $(b_{00} - \sum_{j=1}^{\infty} b_{0j}, b_{01}, b_{02}, \cdots)$ and note that $\lim x_n'(x) = x_0'(x)$ for all x in c. Even though the first coordinate of each sequence $(0, b_{n1}, b_{n2}, \cdots)$ is zero, the first coordinate of x_0' need not be zero; if it is, then the matrix is *conull* while if not, then the matrix is *coregular* [7, page 93]. The distinction between conull and coregular matrices seems minor and yet the two types of matrices are really quite distinct. For example, the identity mapping c onto c is a one-to-one coregular map of c onto itself and in contrast Wilansky [6, Theorem 3, page 243] has shown that a one-to-one conull matrix cannot have a closed range.

1. THEOREM. *Let T be a conull matrix mapping c into c. If the null manifold of T is finite dimensional, then T cannot have a closed range.*

Proof. Let T be written in the form $Tx = (x_n'(x))$, $\lim x_n'(x) = x_0'(x)$, as we have done above. The conjugate (adjoint) operator T' maps l into l and we calculate $T'(a_i) = \sum_{i=1}^{\infty} a_i x_{i-1}'$, for (a_i) in l. Let f be the continuous linear functional

defined on l by $f(a_i)=a_1$. The functionals x_1', x_2', $\cdots$, are all in the null manifold $N(f)$ of f and, since T is conull, x_0' also lies in $N(f)$. Thus the range of T' lies in $N(f)$.

Now suppose that the null manifold $N(T)=T^{-1}(0)$ is finite dimensional and spanned by the vectors $x_1, x_2, \cdots, x_n$. Assume that the range of T is closed. Then [3, Theorem 2, page 487] the range of T' is equal to the set $N(T)^{\perp}=\{x' \text{ in } l: x'(y)=0 \text{ for all } y \text{ in } N(T)\}$ and thus $N(T)^{\perp}\subseteq N(f)$. Let J be the natural map of c into c'', so the linear functional Jy is defined by $Jy(x')=x'(y)$ for all functionals x' on c. From the fact the $N(T)$ is the span of $x_1, x_2, \cdots, x_n$ it follows that

$$N(T)^{\perp} = N(Jx_1) \cap N(Jx_2) \cap \cdots \cap N(Jx_n) \subseteq N(f).$$

Now [7, Theorem 3, page 39] there are scalars $b_1, b_2, \cdots, b_n$ with $f=\sum b_i Jx_i = J(\sum b_i x_i)$. But this is a contradiction since $f \neq Jy$ for any y in c. In fact, letting e_m be the vector in l whose nth coordinate is δ_{mn}, $f(e_{m+1})=0$ while $J(a_i)(e_{m+1})=a_m$ and so if we were to suppose that $f=J(a_i)$, we would find that $(a_i)=0$, obtaining the false conclusion that $f=0$. Hence the range of T cannot be closed.

2. COROLLARY. *There is no matrix isomorphism of c onto c_0.*

Proof. Let T be a matrix mapping c onto c_0. The map T has the form $Tx=(x_n'(x))$ and since the range of T is in c_0 we have $x_0'(x)=\lim x_n'(x)=0$ for all x in c. So not only is T conull, but $x_0'=0$.

We also see from the theorem that there is no matrix projection of c onto c_0, which is noted in [6, page 250].

A conull matrix may have closed range if its null manifold is infinite dimensional. In fact [6, page 250] the matrix

$$\begin{bmatrix} 1 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & \cdot & \cdot \\ 1 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & \cdot & \cdot \\ 1 & 0 & 0 & 0 & 0 & 1 & -1 & 0 & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \end{bmatrix}$$

is a conull map of c onto itself.

A matrix T is said to *sum a sequence* x, say in m, if Tx is in c. It is interesting that a conull matrix always sums a divergent sequence in m [2, see the last paragraph on page 650] and this property is related to the property of Theorem 1. Indeed, Theorem 1 is a consequence of Theorem 3 below and the fact that a conull matrix sums a bounded divergent sequence—a circuitous but informative proof.

The following theorem is given by Berg [2, Theorems 1 and 2, page 651] in the case where T is one-to-one, which is the hard part.

3. THEOREM. *A matrix T mapping c into c sums no bounded divergent sequence if and only if it has a finite dimensional null manifold and a closed range.*

Proof. Suppose that the range of T is not closed. Let

$$M_p = \{(a_i) \text{ in } c: a_1 = a_2 = \cdots = a_p = 0 \text{ and } \lim a_i = 0\}.$$

Then M_p is a closed subspace of c and $c = M_p \oplus F$ where F is a finite dimensional subspace of c. Since $Tc = TM_p + TF$ is the translation of TM_p by a finite dimensional subspace, it is closed if TM_p is closed [7, Corollary 5, page 192]. Thus the range of T restricted to M_p, $T|_{M_p}$, is not closed. If T is not one-to-one on M_p, then we can find a z in M_p of norm one with $Tz = 0$. If T is one-to-one on M_p, then because the range of $T|_{M_p}$ is not closed there is no constant $b > 0$ with $\|Tx\| \geqq b\|x\|$ for all x in M_p. Thus given $\epsilon > 0$ we can find a z of norm two in M_p with $\|Tz\| < \epsilon$. The element $z = (z_i)$ is in c_0, $z = \lim(z_1, z_2, \cdots, z_n, 0, 0, \cdots)$, so for some integer m $\|(z_1, z_2, \cdots, z_m, 0, 0, \cdots)\| \geqq 1$ and $\|T(z_1, z_2, \cdots, z_m, 0, 0, \cdots)\| < \epsilon$. It follows from the lemma of [5] that T sums a bounded divergent sequence.

Suppose that the null manifold of T is infinite dimensional. Then $N(T) \cap M_p$ is not $\{0\}$ for any p and proceeding as above we see that T sums a bounded divergent sequence.

Finally suppose that T sums a bounded divergent sequence. For $x = (x_i)$ in c, let $s(x) = \{i: x_i \neq 0\}$. By the lemma in [5] (and as in the proof given there) we can select a sequence $\{x^n\}$ of elements of c with $s(x^n) \cap s(x^m) = \varnothing$ for $n \neq m$, $\|x^n\| = 1$, and $\|Tx^n\| \leqq 2^{-n}$. Then T, when restricted to the subspace $sp(x^n)$ spanned by the vectors $\{x^n\}$, is the limit in the norm of operators with finite dimensional range and so is compact on that subspace [3, Lemma 3, page 486] and hence is also compact on the closure $\overline{sp}(x^n)$ of that subspace.

Assume that T has a finite dimensional null manifold and a closed range. Write $c = N(T) \oplus M$, M a closed subspace. Then T is one-to-one on M and has a closed range and so, by the open mapping theorem, T has a bounded inverse when restricted to M. Because $N(T)$ is finite dimensional, $M \cap \overline{sp}(x^n)$ is a closed infinite dimensional subspace upon which T is compact and has a bounded inverse. This is a contradiction. (If $T|_M^{-1}$ is continuous, then the product $T|_M^{-1}T$ is compact on $M \cap \overline{sp}(x^n)$ [3, Theorem 4, page 486] and so the unit sphere of $M \cap \overline{sp}(x^n)$ is compact which tells us that the space is finite dimensional [3, Theorem 5, page 245].) Thus T cannot have a finite dimensional null manifold and a closed range if it sums a bounded divergent sequence.

Suppose that T sums no bounded divergent sequence. The operator T may not be a Fredholm operator, because the range of T may not have finite codimension, but it does belong to a class of operators to which the perturbation theory for Fredholm operators has been extended. We recommend [4] for an exposition of this theory. Using these results we can conclude, for example, that if T sums no bounded divergent sequence and B is a matrix mapping c into c with $\|B\| < \gamma(T)$, where $\gamma(T)$ is Kato's perturbation constant (the constant $\gamma(T)$ is called the minimum modulus of T and for one-to-one T is given by $\gamma(T) = 1/\|T^{-1}\|$), then $T + B$ also sums no bounded divergent sequence.

These theorems have also been obtained by J. P. Crawford in a June 1966, Lehigh University Ph.D. thesis.

ELEMENTARY PATH COUNTS

DAVID BLACKWELL AND J. L. HODGES, JR., University of California, Berkeley

1. Introduction. We present new elementary proofs for two known path counts. The material seems suitable for advanced high school classes.

A *path of length* s is a sequence $x=(x_1, \cdots, x_s)$ with each x_i equal to ± 1. We think of x_i as the amount a gambler wins from the ith toss of a coin, so that his net gain from the first i tosses is

$$\sigma_i = x_1 + \cdots + x_i \qquad (\sigma_0 = 0).$$

The polygonal line $\pi = Q_0Q_1 \cdots Q_s$, where $Q_i=(i, \sigma_i)$ will also be called a path of length s, and the line segment $Q_{i-1}Q_i$ will be called the ith *step* of the path. The ith step is *up* or *down* according as $x_i=1$ or $x_i=-1$. The ith step will be called *positive* if both Q_{i-1} and Q_i are on or above the horizontal axis, i.e. if $\sigma_{i-1}\geqq 0$ and $\sigma_i\geqq 0$. The number of positive steps in a path will be called its *lead* and denoted by λ, and a path with lead s, i.e. with every step positive, will be called a *positive path.* The gambler's net gain σ_s at the end of the path will be denoted by γ.

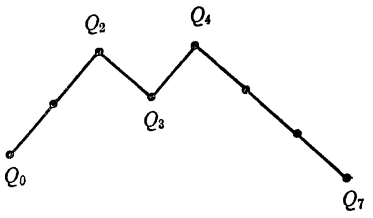

FIG. 1

For instance the path $(1, 1, -1, 1, -1, -1, -1)$ shown in Figure 1 has $s=7$, three steps up, $\lambda=6$, and $\gamma=-1$.

Here are two interesting facts:

A. *The number of positive paths of length s equals the number of paths of length s with* $\gamma = 0$ *if s is even, and equals the number of paths of length s with* $\gamma = 1$ *if s is odd.*

B. *For s even, among the paths of length s with* $\gamma = 0$, *there are equally many with each of the possible leads* $0, 2, \cdots, s$.

Both A and B are known; see Chapter III of Feller's book [2] for example. A is classical and B was discovered by Chung and Feller in 1949. We shall present new and elementary proofs for A and B.

2. Proof of A. For any path of length s, denote by μ the maximum of the numbers $\sigma_0, \sigma_1, \cdots, \sigma_s$: μ is the maximum height of the path, i.e. the maximum net gain the gambler ever experiences.

THEOREM. *Let h be any nonnegative integer. Associate with each path x of length s with* $\mu \geqq h$ *a corresponding path* $\phi(x)$ *of length s, defined as follows. Find the first i for which* $\sigma_i(x) = h$ *and write* $x = yz$, *where y is the initial segment of x with length i. Then* $\phi(x) = zw$, *where w is the path with* $s - i$ *steps obtained from y by reflecting y through a vertical line: if* $y = (a_1, \cdots, a_{s-i})$, $z = (-a_{s-i}, \cdots, -a_1)$. *Then for any integers g, m with* $m \geqq \max(g, h)$, ϕ *is a one-one mapping from the set of all paths of length s with* $\mu = m$, $\gamma = g$ *onto the set of all paths of length s with* $\mu = m - h$, $\gamma = g - 2h$, *so that, denoting by* $N(m, g)$ *the number of paths of length s with* $\mu = m$, $\gamma = g$, *we have*

$$N(m, g) = N(m - h, g - 2h) \quad \text{for} \quad h \geqq 0, m \geqq \max(g, h). \tag{1}$$

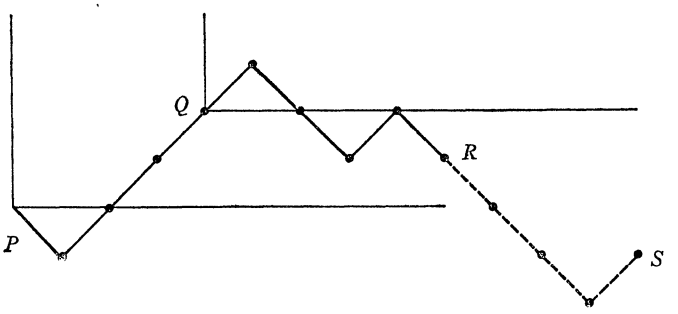

FIG. 2

Figure 2 shows the construction ϕ with $h = 2$, applied to a path with $s = 9$. The polygonal lines PQ, QR, RS are the paths y, z, w respectively. The function ϕ maps the path PQR into the path QRS.

Proof of Theorem. Clearly ϕ decreases μ by h and γ by $2h$. Moreover, any path v of length s with $\gamma \leqq \mu - h$ is the ϕ-image of a unique x. To find x, find the shortest final segment w of v with $\gamma(w) = -h$. Say $v = zw$. Then $x = yz$, where y is obtained from w by reflection in a vertical line.

To obtain A from (1), for s even, take any $m \geqq 0$, set $h=m$ and $g=0$ in (1), obtaining

$$N(m, 0) = N(0, -2m). \tag{2}$$

Now sum (2) over $m \geqq 0$ obtaining, for s even,

$$\#\{\gamma = 0\} = \#\{\mu = 0\}. \tag{3}$$

But the paths with $\mu=0$ are just the paths with no positive steps, which are clearly equinumerous, by reflection in a horizontal line, with the positive paths.

To obtain A from (1), for s odd, take any $m \geqq 1$, set $h=m$ and $g=1$ in (1), obtaining

$$N(m, 1) = N(0, 1 - 2m). \tag{4}$$

Sum (4) over $m \geqq 1$ obtaining, for s odd, $\#\{\gamma=1\} = \#\{\mu=0\}$. As with even s, $\#\{\mu=0\}$ equals the number of positive paths.

3. Proof of B. Take any path π of even length $s=2k$ and gain 0. Then π has exactly k steps up. Denote any one of these steps up by p, write $\pi=apb$, and say that $\pi_1=bpa$ is obtained from π by *switching at* p. The path π_1 will also have gain 0. We assert that π_1 and π have different leads. To see this, note that $0=\gamma(\pi)=\gamma(a)+1+\gamma(b)$, so that exactly one of the two numbers $\gamma(a)$, $\gamma(b)$ is nonnegative. Suppose that $\gamma(a) \geqq 0$, $\gamma(b)<0$. We check that $\lambda(\pi)>\lambda(\pi_1)$ by comparing the positive steps in each of the three parts a, p, b. In π, a starts at height 0 while in π_1 it starts at height $\gamma(b)+1 \leqq 0$, so any step in a which is positive in π_1 is also positive in π. Similarly b starts at height 0 in π_1 and at height $\gamma(a)+1>0$ in π, so every b step which is positive in π_1 is also positive in π. Finally p is itself a positive step in π, starting at $\gamma(a) \geqq 0$, but not in π_1, starting at $\gamma(b)<0$. So $\lambda(\pi)>\lambda(\pi_1)$.

Next note that if π_1, π_2 are obtained from π by switching at different p's, either is obtained directly from the other by switching:

$$\pi = apbpc$$
$$\pi_1 = bpcpa$$
$$\pi_2 = cpapb.$$

So π_1, π_2 have different leads.

Thus if we call two paths *equivalent* if they are identical or if one is obtained from the other by switching, each equivalence class contains $k+1$ paths, no two of which have the same lead. Since the only possible leads are the $k+1$ numbers $0, 2, \cdots, 2k$, there is exactly one path in each class with each lead.

The special case of lead $2k$ (or 0) is obtained in essentially this way by Dvoretzky and Motzkin [1].

MATHEMATICAL NOTES

A NOTE ON MATRIX QUADRATIC RESIDUES

AZRIEL ROSENFELD, University of Maryland

1. Introduction. Let $A=(a_{ij})$, $B=(b_{ij})$ be n by n matrices of integers; we shall call A and B congruent modulo k (written $A\equiv B \pmod{k}$) if $a_{ij}\equiv b_{ij} \pmod{k}$ for all $1\leqq i, j\leqq n$. Evidently, there are just k^{n^2} n-by-n integral matrices which are incongruent mod k.

The study of matrix congruences, as just defined, is a natural generalization of the study of congruences in residue rings of the integers, but few of the methods used in classical congruence theory have direct generalizations to matrix congruences.

This note deals with the problem of enumerating the 2-by-2 integral matrices which are congruent to squares of 2-by-2 integral matrices modulo an odd prime p; we call such matrices "squares" in what follows.

2. Scalar Squares.

PROPOSITION 1. *Every scalar matrix is a square. Furthermore, the number of incongruent matrix square roots of*

$$\begin{pmatrix} k & 0 \\ 0 & k \end{pmatrix}$$

is

(A) p^2, *if* $k\equiv 0$,
(B) p^2+p+2, *if* $k\not\equiv 0$ *is a quadratic residue of* p,
(C) p^2-p, *if* k *is a quadratic nonresidue of* p.

Proof. Let

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^2 \equiv \begin{pmatrix} k & 0 \\ 0 & k \end{pmatrix};$$

then $a^2+bc\equiv d^2+bc\equiv k$ and $b(a+d)\equiv c(a+d)\equiv 0$, so that $b\equiv c\equiv 0$ or $a+d\equiv 0$. In the former case, $a^2\equiv d^2\equiv k$, so that k must be a quadratic residue of p and a, d (independently) $\equiv \pm k$. In the latter case $a^2\equiv d^2$ and b, c can be any integers

satisfying $bc \equiv k - a^2$. The enumeration of the square roots in the three cases of the proposition now proceeds as follows:

(A) $k \equiv 0$: Here $b \equiv c \equiv 0$ requires $a^2 \equiv d^2 \equiv 0$ or $a \equiv d \equiv 0$; it thus suffices to consider the case $a + d \equiv 0$, which here implies $bc \equiv -a^2$. If $a \equiv 0$, this is satisfied by $2p - 1$ incongruent pairs (b, c), namely those for which b or $c \equiv 0$ (this includes the pair $b \equiv c \equiv 0$). If $a \not\equiv 0$, it is satisfied by just $p - 1$ such pairs, since b can be anything $\not\equiv 0$ and c is then determined as $-a^2/b$. Since there are $p - 1$ a's $\not\equiv 0$, the total number of incongruent square roots of the zero matrix is thus $2p - 1 + (p-1)^2 = p^2$.

(B) $k \not\equiv 0$, a quadratic residue: The case $b \equiv c \equiv 0$ yields just four square roots. If $a + d \equiv 0$, there are two subcases: If $a^2 \equiv k$, b or c (but not both, since this case has already been counted) must $\equiv 0$; thus, for each of the two incongruent a's such that $a^2 \equiv k$, there are $2(p-1)$ incongruent pairs (b, c) which yield a square root. If $a^2 \not\equiv k$ (there being $p - 2$ such a's), there are as in case (A) just $p - 1$ incongruent pairs (b, c) such that $bc \equiv k - a^2 \not\equiv 0$. The total number of incongruent square roots for this type of k is thus $4 + 2 \cdot 2(p-1) + (p-2) \cdot (p-1) = p^2 + p + 2$.

(C) k a quadratic nonresidue: Here $b \equiv c \equiv 0$ yields no square roots, while $a + d \equiv 0$ yields $p - 1$ incongruent pairs (b, c) for each of the p incongruent a's, since $k - a^2$ cannot be $\equiv 0$. The number of incongruent square roots in this case is thus just $p(p-1) = p^2 - p$.

3. Nonscalar squares. In contrast to Proposition 1, by which a scalar matrix has at least $p^2 - p \geqq 6$ square roots, we have for nonscalar matrices

PROPOSITION 2. *A nonscalar square has at most four incongruent square roots.*

Proof. Let

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^2 \equiv \begin{pmatrix} e & f \\ g & h \end{pmatrix}^2 \equiv M,$$

so that

(1) $a^2 + bc \equiv e^2 + fg$, (3) $b(a + d) \equiv f(e + h)$,

(2) $d^2 + bc \equiv h^2 + fg$, (4) $c(a + d) \equiv g(e + h)$.

If M is nonscalar, $a + d$ and $e + h$ cannot $\equiv 0$. Suppose that $b \not\equiv 0$; then $f \not\equiv 0$, and we can solve (3) for $e + h$, (1) and (2) for $e^2 - h^2$, thus obtaining $e - h$, whence e and h, in terms of a, b, d, f as

$$e + h = b(a + d)/f, \qquad e - h = f(a - d)/b, \qquad g = fc/b.$$

Substituting for g and e in (1) (or g and h in (2)) yields a quadratic congruence in $(f^{-1}b)^2$ which has the roots 1 and

$$\frac{(a - d)^2 + 4bc}{(a + d)^2},$$

where it will be noted that $D=(a-d)^2+4bc$ is the discriminant of the characteristic polynomial of

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

If D is a quadratic residue, we thus have $f\equiv \pm b$, $\pm b(a+d)/\sqrt{D}$; if D is a nonresidue, only $f\equiv \pm b$, and in either case there are at most four possible matrices

$$\begin{pmatrix} e & f \\ g & h \end{pmatrix}.$$

If $b\equiv 0$ but $c\not\equiv 0$, an analogous argument leads to the same conclusion. But if $b\equiv c\equiv 0$, since $e+h\not\equiv 0$ we have $f\equiv g\equiv 0$, $a^2\equiv e^2$, $d^2\equiv h^2$, so that $e\equiv \pm a$, $h\equiv \pm d$ (where the signs are independent), and again M has at most four incongruent square roots.

4. Diagonalizable squares.

PROPOSITION 3. *A diagonalizable matrix which is not a scalar matrix is a square if and only if its eigenvalues are quadratic residues. Furthermore, such a square diagonalizable matrix has exactly four incongruent square roots unless one of its eigenvalues is congruent to zero, in which case it has exactly two incongruent square roots.*

Proof. If M is diagonalizable but not scalar, there exists a nonsingular matrix P such that

$$PMP^{-1} \equiv \begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix},$$

where $h\not\equiv k$ are the eigenvalues of M. If h and k are quadratic residues, say $h\equiv r^2$, $k\equiv s^2$, then

$$\begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix} \equiv \begin{pmatrix} r & 0 \\ 0 & s \end{pmatrix}^2, \quad \text{and} \quad M \equiv P^{-1}\begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix} P \equiv \left[P^{-1}\begin{pmatrix} r & 0 \\ 0 & s \end{pmatrix} P\right]^2.$$

Conversely, suppose that M is a square, say $M\equiv N^2$; then

$$\begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix} \equiv PMP^{-1} \equiv (PNP^{-1})^2.$$

Now

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^2 \equiv \begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix}$$

implies $b(a+d)\equiv c(a+d)\equiv 0$ and $a^2+bc\equiv h$, $d^2+bc\equiv k$. Since $h\not\equiv k$, $a+d$ cannot

$\equiv 0$; hence $b \equiv c \equiv 0$ and $h \equiv a^2$, $k \equiv d^2$. Furthermore,

$$\begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix}$$

has just the incongruent square roots

$$\begin{pmatrix} \pm a & 0 \\ 0 & \pm d \end{pmatrix},$$

where the signs are independent; there are four of these if neither h nor $k \equiv 0$, and two if h or $k \equiv 0$. Since the square roots of M are in one-to-one correspondence with those of

$$\begin{pmatrix} h & 0 \\ 0 & k \end{pmatrix},$$

the proof of the proposition is complete.

5. Classification of squares. Since $(-M)^2 = M^2$, it is clear that every square except the zero matrix has an even number of (in particular, at least two) incongruent square roots. This observation is sharpened by

PROPOSITION 4. *A matrix has more than four incongruent square roots if and only if it is scalar; exactly four incongruent square roots, if and only if it has incongruent nonzero eigenvalues which are quadratic residues; and no or two incongruent square roots, otherwise.*

Proof. The first part is just Propositions 1–2. If M has eigenvalues which are incongruent to each other and to zero, it must be diagonalizable and hence has exactly four incongruent square roots by Proposition 3. Conversely, by the proof of Proposition 2, if

$$M \equiv \begin{pmatrix} a & b \\ c & d \end{pmatrix}^2$$

is nonscalar and $b \equiv c \equiv 0$, M itself is diagonal, and its square roots

$$\begin{pmatrix} \pm a & 0 \\ 0 & \pm d \end{pmatrix}$$

are all incongruent if and only if $a, d \not\equiv 0$, while $a \not\equiv d$ since M is nonscalar. But if $b \not\equiv 0$ (and similarly if $c \not\equiv 0$), M can have four square roots only if D, the discriminant of the characteristic polynomial of

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

is a nonzero quadratic residue, which is equivalent to the existence of two incongruent eigenvalues for

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Since M is nonscalar, it too then has two incongruent eigenvalues, the squares of those of

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

and so is diagonalizable; by Proposition 3, its four square roots are thus incongruent only if neither of its eigenvalues is zero. Finally, if M has less than four incongruent square roots, it has either none or tow by the remark just preceding this Proposition.

6. Enumeration of squares. Propositions 1–4 may be applied to an enumeration of the 2 by 2 matrices which are congruent to squares mod p as follows:

By Proposition 1, the p incongruent scalar matrices have a total of

$$p^2 + \frac{p-1}{2}(p^2+p+2) + \frac{p-1}{2}(p^2-p) = p^3 + p - 1$$

incongruent square roots. By Proposition 3, the diagonalizable matrices which have incongruent nonzero quadratic residue eigenvalues each have exactly four square roots. To enumerate these explicitly, we use

LEMMA 1. *There are* $p(p+1)(p-1)^2$ *incongruent nonsingular matrices.*

Proof.

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

is nonsingular if and only if $ad \not\equiv bc$. If $b \equiv 0$, this is equivalent to $ad \not\equiv 0$; this is satisfied by any c and by any $a \not\equiv 0$, $d \not\equiv 0$—a total of $p(p-1)^2$ incongruent possibilities. If $b \not\equiv 0$, this is equivalent to $c \not\equiv adb^{-1}$, which is satisfied by $p-1$ incongruent c's for any a, any d, and any $b \not\equiv 0$—a total of $p^2(p-1)^2$ incongruent possibilities. The number of incongruent nonsingular matrices is thus $p(p+1)(p-1)^2$.

LEMMA 2. *A nonscalar diagonal matrix is similar to* $p(p+1)$ *incongruent matrices.*

Proof. Let

$$D = \begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix}$$

be diagonal, let P and Q be nonsingular, and suppose that $PDP^{-1} \equiv QDQ^{-1}$; then $Q^{-1}P$ commutes with D. Now

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix} \equiv \begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

requires $ub \equiv vb$, $uc \equiv vc$. Since D is nonscalar, $u \not\equiv v$; hence this implies $b \equiv c \equiv 0$, so that $Q^{-1}P$ must be diagonal,

$$\text{say} \equiv \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix},$$

where $ad \not\equiv 0$ insures nonsingularity. It follows that for each nonsingular Q, all the P's of the form

$$Q\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix},$$

where $ad \not\equiv 0$, have the property that $QDQ^{-1} \equiv PDP^{-1}$. The number of incongruent matrices which are similar to D is thus equal to the number of nonsingular Q's (found in Lemma 1) divided by the number of such P's, which is clearly the same as the number of such

$$\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\text{'s}$$

or $(p-1)^2$; this immediately proves the Lemma.

Now the number of incongruent diagonal matrices which have incongruent nonzero quadratic residues as diagonal terms is clearly

$$\frac{p-1}{2} \cdot \frac{p-3}{2};$$

however, since

$$\begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix}$$

is similar to

$$\begin{pmatrix} v & 0 \\ 0 & u \end{pmatrix},$$

only half of these should be counted. It follows by Propositions 3 and 4 and Lemma 2 that the number of incongruent matrices which have exactly four incongruent square roots is

$$\frac{p(p+1)(p-1)(p-3)}{8}.$$

The number of incongruent square roots of such matrices is thus

$$\frac{p(p+1)(p-1)(p-3)}{2} \quad \text{or} \quad \frac{p^4-3p^3-p^2+3p}{2}.$$

By Proposition 4, finally, if a matrix is not the square root of a scalar matrix or of a matrix which has incongruent nonzero quadratic residue eigenvalues, its square has exactly two incongruent square roots. Now the number of such matrices is just

$$p^4-(p^3+p-1)-\frac{p^4-3p^3-p^2+3p}{2}=\frac{p^4+p^3+p^2-5p+2}{2};$$

hence the number of incongruent squares not yet counted is just half of this. It follows that the total number of incongruent squares is

$$p+\frac{p^4-3p^3-p^2+3p}{8}+\frac{p^4+p^3+p^2-5p+2}{4}=\frac{3p^4-p^3+p^2+p+4}{8}.$$

It is of interest to enumerate separately the singular and nonsingular squares. To this end, note that the scalar matrices are all nonsingular with the exception of the zero matrix, and that the matrices which have exactly four incongruent square roots are all nonsingular. Since a matrix is singular if and only if its square is singular, it follows by Lemma 1 and Proposition 1 that the number of incongruent singular matrices whose squares have exactly two square roots is $p^4-p(p+1)(p-1)^2-p^2$ or p^3-p. The number of incongruent singular squares is thus $\{(p^3-p)/2\}+1$. Combining this with the total number of incongruent squares found above, the results of this section may be summed up in

PROPOSITION 5. *There are*

$$\frac{p^3-p+2}{2}=\frac{p(p^2-1)}{2}+1$$

incongruent singular squares, and

$$\frac{3p^4-5p^3+p^2+5p-4}{8}=\frac{p^2-1}{8}(3p^2-5p+4)$$

incongruent nonsingular squares.

The author wishes to express his appreciation to the referee for calling his attention to "Scalar Polynomial Equations for Matrices over a Finite Field" by John H. Hodges [Duke Math. J., 25 (1958) 291–296], which treats the more general problem of enumerating the roots of an arbitrary polynomial matrix equation over a finite field, with emphasis on the case of matrix roots of unity.

ON THE NUMBER OF PAIRS OF GENERALIZED INTEGERS WITH LEAST COMMON MULTIPLE NOT EXCEEDING x

E. M. HORADAM, The University of New England, Australia

Generalized Integers are defined as follows: Suppose there is given a finite or infinite sequence $\{p\}$ of real numbers which we will call generalized primes such that $1 < p_1 < p_2 < \cdots$. Form the set $\{l\}$ of all p-products, i.e., products $p_1^{v_1}p_2^{v_2}\cdots$, where $v_1, v_2, \cdots$, are integers $\geqq 0$ of which all but a finite number are 0. Call these numbers generalized integers and suppose that the semigroup consisting of all these products is free. Then assume $\{l\}$ may be arranged as an increasing sequence: $1 = l_1 < l_2 < l_3 < \cdots, < l_n < \cdots$. Let $[x]$ denote the number of generalized integers $\leqq x$ and assume that

$$[x] = x + R(x) \quad \text{where} \quad R(x) = O(x^\alpha) \quad \text{and} \quad 0 < \alpha < 1. \tag{1}$$

This assumption, incidentally, ensures that the number of generalized primes is infinite. We say $d \mid l_n$ if $d \in \{l\}$ and there exists $\delta \in \{l\}$ such that $d\delta = l_n$.

Denote by (l_r, l_s) the greatest common divisor of l_r and l_s. Then the number d is a unitary divisor of l_n if $(d, \delta) = 1$. Let $[l_r, l_s]$ denote the least common multiple of l_r and l_s; $\tau^*(l_n)$ denote the number of unitary divisors of l_n; $t(l_n)$ denote the number of ordered pairs of generalized integers l_r and l_s with $[l_r, l_s] = l_n$ and $\theta(x)$ the number of ordered pairs of generalized integers with least common multiple not exceeding x.

The object of this note is to find an estimate for $\theta(x)$ using the result given in [1]; namely

$$T^*(x) = \sum_{l_n \leqq x} \tau^*(l_n) = \frac{x}{\zeta(2)}\left\{\log x - \frac{2\zeta'(2)}{\zeta(2)} + 2\gamma_1 - 1\right\} + O(x^{(1+\alpha)/2}), \tag{2}$$

where

$$\zeta(s) = \sum_{l_n=1}^{\infty} l_n^{-s} \quad (s > 1),$$

and $\zeta'(s)$ is its derivative.

Again, as described in [2], Abel's theorem is used together with assumption (1) to give the following results, (γ_β, γ_1 and δ_1 are constants),

$$\sum_{l_n \leqq x} \frac{1}{l_n^\beta} = \frac{x^{1-\beta}}{1-\beta} + \gamma_\beta + O(x^{\alpha-\beta}), \qquad \beta \neq 1, \tag{3}$$

$$\sum_{l_n \leqq x} \frac{1}{l_n} = \log x + \gamma_1 + O(x^{\alpha-1}), \tag{4}$$

$$\sum_{l_n \leqq x} \frac{\log l_n}{l_n} = \frac{1}{2}\log^2 x + \delta_1 + O(x^{\alpha-1}\log x). \tag{5}$$

THEOREM.

$$\theta(x) = \frac{x \log x}{\zeta(2)}\left\{\frac{\log x}{2} - 2\frac{\zeta'(2)}{\zeta(2)} + 3\gamma_1 - 1\right\} + O(x).$$

Proof. The proof given by Cesàro in [3] that $t(n) = \sum_{d|n} \tau^*(d)$ is immediately applicable to generalized integers giving

$$t(l_n) = \sum_{d|l_n} \tau^*(d). \tag{6}$$

Then $\theta(x) = \sum_{l_n \leqq x} t(l_n)$ (by definition), $= \sum_{l_n \leqq x} \sum_{d|l_n} \tau^*(d)$ (from (6)), $= \sum_{d\delta \leqq x} \tau^*(d) = \sum_{\delta \leqq x} \sum_{d \leqq x/\delta} \tau^*(d) = \sum_{\delta \leqq x} T^*(x/\delta)$ and, after substitution from (2)

$$\begin{aligned}
\theta(x) &= \sum_{\delta \leqq x}\left[\frac{x}{\zeta(2)}\cdot\frac{1}{\delta}\left\{\log x - \log\delta - \frac{2\zeta'(2)}{\zeta(2)} + 2\gamma_1 - 1\right\} + O\left(\frac{x}{\delta}\right)^{(1+\alpha)/2}\right] \\
&= \frac{x}{\zeta(2)}\left(\log x - 2\frac{\zeta'(2)}{\zeta(2)} + 2\gamma_1 - 1\right)\sum_{\delta \leqq x}\frac{1}{\delta} \\
&\quad - \frac{x}{\zeta(2)}\sum_{\delta \leqq x}\frac{\log\delta}{\delta} + O\left\{x^{(1+\alpha)/2}\sum_{\delta \leqq x}\left(\frac{1}{\delta}\right)^{(1+\alpha)/2}\right\} \\
&= \frac{x}{\zeta(2)}\left(\log x - 2\frac{\zeta'(2)}{\zeta(2)} + 2\gamma_1 - 1\right)(\log x + \gamma_1 + O(x^{\alpha-1})) \\
&\quad - \frac{x}{\zeta(2)}\left(\tfrac{1}{2}\log^2 x + \delta_1 + O(x^{\alpha-1}\log x)\right) + O(x^{(1+\alpha)/2}\cdot x^{1-(1+\alpha)/2})
\end{aligned}$$

(from (3), (4) and (5))

$$= \frac{x \log x}{\zeta(2)}\left(\frac{\log x}{2} - 2\frac{\zeta'(2)}{\zeta(2)} + 3\gamma_1 - 1\right) + O(x).$$

This is the required result.

A more exact estimation of $\theta(x)$ for natural numbers using nonelementary methods is given by H. Jager in [4].

A RING OF SEQUENCES GENERATED BY RATIONAL FUNCTIONS

D. A. KLARNER, McMaster University, Canada

1. A Ring of Sequences. Let D represent the set of all sequences of complex numbers which satisfy linear homogeneous difference equations with constant coefficients: that is, a sequence of complex numbers $\{a_n\}$ is in D if, and only if, there exist constants $\alpha_1, \alpha_2, \cdots, \alpha_k$ such that $\alpha_1 \neq 0$ and

$$\alpha_1 a_n + \alpha_2 a_{n+1} + \cdots + \alpha_k a_{n+k-1} = a_{n+k}, \qquad n = 0, 1, \cdots. \tag{1}$$

Another necessary and sufficient condition that $\{a_n\}$ belongs to D is that there exist polynomials $p(x)$ and $q(x)$ such that

$$p(x)/q(x) = \sum_{n=0}^{\infty} a_n x^n, \tag{2}$$

with the degree of q greater than the degree of p; we will refer to p/q as the generator of $\{a_n\}$.

The following theorem, though apparently known by some mathematicians, seems to appear nowhere in the literature.

THEOREM 1. *The sequences of D form a commutative ring under term by term addition and multiplication.*

Before giving a proof of this theorem, we note that the sequences of D do not form an integral domain under these operations since the sequences $\{1, 0, 1, 0, \cdots\}$ and $\{0, 1, 0, 1, \cdots\}$ generated by $1/(1-x^2)$ and $x/(1-x^2)$, respectively, have the product $\{0, 0, 0, 0, \cdots\}$ which is the zero of the ring.

Proof of the Theorem. The additive identity of the ring is $\{0\}$ and the multiplicative identity is $\{1\}$, generated by $1/(1-x)$. Since the generator of $\{a_n+b_n\}$ is found by adding the generators of $\{a_n\}$ and $\{b_n\}$, it is clear that the sequences of D form an additive Abelian group. In fact, the only ring property which is not immediately obvious is that the term by term product of any two sequences in D is also in D. To prove this we recall an observation due to Hadamard [5]: If $A(x) = \sum a_n x^n$, $B(x) = \sum b_n x^n$, and $C(x) = \sum a_n b_n x^n$, then

$$C(x) = \frac{1}{2\pi i} \int_\gamma A\left(\frac{x}{s}\right) B(s) \frac{ds}{s}, \tag{3}$$

where γ is a contour in the s plane which includes the singularities of $A(x/s)/s$ and excludes the singularities of $B(s)$.

Suppose $p(x)$ is a polynomial of degree less than n and let $A(x) = p(x)/(1-\theta_1 x)^{e_1} \cdots (1-\theta_k x)^{e_k}$ with the θ_j distinct and $e_1+e_2+\cdots+e_j=n$; then

$$\frac{1}{2\pi i} \int_\gamma A\left(\frac{x}{s}\right) B(s) \frac{ds}{s}$$

$$(4) \qquad = \frac{1}{2\pi i}\int_{\gamma} \frac{s^{n-1}p(x/s)B(s)ds}{(s-\theta_1 x)^{e_1}\cdots(s-\theta_k x)^{e_k}}$$

$$= \sum_{j=1}^{k} \frac{1}{e_j!}\frac{\partial^{e_j-1}}{\partial s^{e_j-1}}\left\{\frac{s^{n-1}p(x/s)B(s)}{(s-\theta_1 x)^{e_1}\cdots(s-\theta_{j-1}x)^{e_{j-1}}(s-\theta_{j+1}x)^{e_{j+1}}\cdots}\right\}.$$

Now if B is a rational function, then so is the last member of (4); in fact, each of the summands in the last member of (4) generate sequences in D. Hence $\{a_n \cdot b_n\}$ is in D if $\{a_n\}$ and $\{b_n\}$ are in D.

Rational functions p/q, with the coefficients of p and q real numbers or integers and the degree of p less than the degree of q, generate sequences of real or rational numbers respectively; these subsets of D also form subrings of the ring D. The subset K of D which contains only sequences of integers is also a subring of D. A characterization of the generating functions of the sequences in K was given by Fatou.

THEOREM 2. *If $\{a_n\}$ is a sequence of integers generated by an irreducible rational function p/q, then p and q are polynomials with integer coefficients and $q(0)=1$.*

A proof of this theorem can be found in Salem's book [4].

One of the implications of the fact that K is a ring under term by term addition and multiplication is that $\{a_n^k\} \in K$ if $\{a_n\} \in K$. If p_k/q_k is the generating function of $\{a_n^k\}$ we can use (4) to find a recurrence formula for $\{p_k/q_k\}$; in fact, going back to (3),

$$(5) \qquad \frac{p_{k+1}(x)}{q_{k+1}(x)} = \frac{1}{2\pi i}\int_{\gamma} \frac{p_1(x/s)}{q_1(x/s)}\frac{p_k(s)}{q_k(s)}\frac{ds}{s},$$

where γ is defined as in (3); the integration is trivial if we know the order of the zeros in the s plane of $q_1(x/s)$.

Riordan [3] found generating functions for the kth powers of the Fibonacci numbers ($F_0=0$, $F_1=1$, $F_{n+2}=F_{n+1}+F_n$), and Carlitz [1] generalized these results to arbitrary second order sequences. Gould [2] has also discussed the generating functions of powers of certain second order sequences. We should note that the methods employed by these authors could be generalized to treat the sequences under discussion here; our introduction of the contour integral may be justified, however, from the point of view that proofs are shortened.

2. Some Algebraic Properties of K. We now turn our attention to the problem of characterizing the associates of the multiplicative unit in K. To do this we prove

THEOREM 3. *Let $\{a_n\} \in D$ and suppose $\{a_n\}$ has only a finite number of distinct range elements, then $\{a_n\}$ is periodic and is generated by the not necessarily irreducible rational function $p(x)/(1-x^p)$, where p is the length of some period of $\{a_n\}$.*

Proof. Suppose $\{a_n\} \in D$ with

$$\alpha_1 a_n + \alpha_2 a_{n+1} + \cdots + \alpha_j a_{n+j-1} = a_{n+j}, \qquad n = 0, 1, \cdots, \tag{6}$$

and that the range of $\{a_n\}$ contains exactly k elements.

The maximum number of distinct ordered sets $A_n = (a_n, a_{n+1}, \cdots, a_{n+j-1})$ is less than or equal to k^j since a_{n+i} can be selected in k ways for $i = 0, \cdots, j-1$. Thus, some pair of the ordered sets $A_0, A_j, \cdots, A_{jk^j}$ must be identical, say $A_{rj} = A_{sj}$ with r minimal. Using (6) we see that

$$(a_{rj}, \cdots, a_{sj-1}) = (a_{sj}, \cdots, a_{2sj-rj-1});$$

consequently, $\{a_n\}$ is periodic from a_{rj} onward with period of length $sj-rj$. This gives

$$\begin{aligned} \sum_{n=0}^{\infty} a_n X^n &= \sum_{n=0}^{rj-1} a_n X^n + \sum_{n=0}^{\infty} (a_{rj}X^{rj} + \cdots + a_{sj-1}X^{sj-1})X^{jn(s-r)} \\ &= \frac{a_{rj}X^{rj} + \cdots + a_{sj-1}X^{sj-1} + (1 - X^{js-jr}) \sum_{n=0}^{rj-1} a_n X^n}{1 - X^{js-jr}}. \end{aligned} \tag{7}$$

Collecting the coefficients of x^n in the numerator of the rational function in (7) we have

$$\begin{aligned} &(a_{sj-1} - a_{rj-1})X^{sj-1} + (a_{sj-2} - a_{rj-2})X^{sj-2} + \cdots \\ &\qquad + (a_{sj-j} - a_{rj-j})X^{sj-j} + \cdots; \end{aligned} \tag{8}$$

but not all of the quantities $a_{sj-i} - a_{rj-i} = 0$ for $i = 1, 2, \cdots, j$ since this would contradict the minimal property of r. Hence the degree of the polynomial in (8) is $js-i$ where $i < j$. Since $\{a_n\} \in D$ we must have $js-jr > js-i$, hence $r = 0$. Thus,

$$\sum_{n=0}^{\infty} a_n x^n = \frac{p(x)}{1 - x^{js}}, \tag{9}$$

where the degree of $p(x)$ is less than js, which implies $\{a_n\}$ is periodic. This completes the proof.

COROLLARY. *A sequence $\{a_n\} \in K$ is a divisor of $\{1, 1, \cdots\}$ if, and only if, $\{a_n\}$ is a periodic sequence of positive and negative units.*

Proof. This is an immediate consequence of Theorem 3 and the definition of K.

Ordinarily, in a commutative ring R with a unit, we say an element $r \in R$ is irreducible if, and only if, every factorization $r = r_1 \cdot r_2$ implies r_1 or r_2 is a unit of R. Adopting this convention for the ring K, it turns out that the only irreducible elements in K are the units of K. To prove this suppose the contrary; then if $\{a_n\}$ is not a unit and is irreducible there are at least two elements a_i, a_j of $\{a_n\}$ such that $|a_i|, |a_j| \neq 1$. It is easy to check that the sequences

$$A = \{a_0, \cdots, a_i, \cdots, a_{j-1}, 1, 1, \cdots, 1, a_{2j}, \cdots, a_{2j-1}, 1, 1, \cdots, 1, a_{4j}, \cdots\} \tag{10}$$

(11) $B=\{1, \cdots, 1, \cdots, 1, a_j, a_{j+1}, \cdots, a_{2j-1}, 1, 1, \cdots, 1, a_{2j}, \cdots, a_{4j-1}, 1, \cdots\}$

are elements of K; since $a_i \in A$, $a_j \in B$ and $A \times B = \{a_n\}$ we have a contradiction.

Another interesting example of factorization in K is the following: Let $\{F_n\}$ denote the Fibonacci sequence and recall that F_a divides F_{ab} for all natural numbers b. The sequence $\{a_n\}$ defined by

$$a_n = \begin{cases} F_n/F_j, & \text{if } j \text{ divides } n \\ F_n, & \text{otherwise} \end{cases} \tag{12}$$

is generated by a rational function since the periodic sequence $\{1, 1, \cdots, 1/F_j, 1, 1, \cdots, 1/F_j, \cdots\}$ and $\{F_n\}$ are both generated by rational functions; furthermore $\{a_n\}$ is a sequence of integers and is therefore in K. Also, the periodic sequence $F=\{1, 1, \cdots, F_j, 1, 1, \cdots, F_j, \cdots\}$ is in K; clearly $\{a_n\} \times F = \{F_n\}$. In this and the previous example, certain periodic subsequences have made it possible to factor sequences of K in a highly artificial way. For example, it would be more interesting to say an increasing sequence in K is irreducible if it has no factors which are increasing sequences in K. It seems difficult to ascertain whether or not the Fibonacci or Lucas sequences are irreducible in this sense.

SUMS OF SQUARES OF POLYNOMIALS WITH COEFFICIENTS IN A FINITE FIELD

WILLIAM LEAHEY, University of Illinois

Let F be a finite field of odd characteristic p and denote by $F[X]$ the ring of polynomials with coefficients in F. Suppose $f(X) \in F[X]$. When do there exist $g(X)$, $h(X) \in F[X]$ such that $f(X) = (g(X))^2 + (h(X))^2$? This question and the questions of the representation of $f(X)$ as a sum of an arbitrary number of squares and the number of such representations have been studied in great detail in a series of papers by L. Carlitz and E. Cohen (see bibliography). These authors obtain necessary and sufficient conditions for representability and the

number of possible representations. In particular, in [5, section 5] Cohen deals explicitly with the problem of expressing a polynomial as a sum of two squares.

The object of this paper is to give a simple and somewhat different criterion for deciding when a polynomial can be written as a sum of two squares. In fact the theorem to be proved is very much analogous to the well-known theorem of Fermat [7, Chapter V] on the representability of a positive integer as a sum of two squares. The irreducible polynomials of even degree play the role of the primes congruent to 1 modulo 4 and the irreducible polynomials of odd degree play the role of the primes congruent to 3 modulo 4. The following lemma will be used.

LEMMA. *Let F be a finite field and suppose $a \in F$. Then there exist $b, c \in F$ such that $a = b^2 + c^2$.*

Proof. Let F have order p^n. If $p = 2$ then the map $x \to x^2$ is onto. Thus for any $a \in F$ there exists an $x \in F$ such that $a = x^2 = x^2 + 0^2$.

For p odd the image of $x \to x^2$ contains $t = (p^n - 1)/2 + 1$ elements. Let these elements be $x_1^2, x_2^2, \cdots, x_t^2$. Now for $a \in F$ the elements $a - x_1^2, a - x_2^2, \cdots, a - x_t^2$ are all distinct. Since $2t = p^n + 1 > p^n$ it follows that $\{a - x_1^2, \cdots, a - x_t^2\} \cap \{x_1^2, \cdots, x_t^2\}$ is not empty. Therefore there exist j and k such that $a - x_j^2 = x_k^2$, i.e. $a = x_j^2 + x_k^2$. This completes the proof of the lemma.

Before stating the theorem, we note that if $i = \sqrt{-1} \in F$, then any $f(X) \in F[X]$ can always be written as a sum of two squares. Thus one can write

$$f(X) = [(f(X) + 1)/2]^2 + (i)^2 \cdot [(f(X) - 1)/2]^2.$$

If $p \equiv 1 \pmod 4$ then F contains i. On the other hand if $p \equiv 3 \pmod 4$ then F contains i if and only if the order of F is p^n with n even. Thus the fields F of interest are those of order p^n with $p \equiv 3 \pmod 4$ and n odd.

THEOREM. *Let F be a finite field of order p^n where p is a prime congruent to 3 modulo 4 and n is odd. Let $f(X) \in F[X]$ and suppose that*

$$f(X) = a(f_1(X))^{e_1} \cdots (f_s(X))^{e_s}$$

with $a \in F$, and $f_j(X) \in F[X]$ is the factorization of $f(X)$ into an element of F and monic irreducible polynomials in $F[X]$. Then $f(X)$ can be written as a sum of two squares if and only if e_j is even for those polynomials $f_j(X)$ which are of odd degree.

Proof. Suppose that $f(X) = (g(X))^2 + (h(X))^2$. Let $f_j(X)$ be an irreducible factor of $f(X)$ of odd degree k and suppose that e_j is odd. If neither $g(X)$ nor $h(X)$ is divisible by $f_j(X)$ then $(g(X))^2 \equiv -(h(X))^2 \pmod{f_j(X)}$. Furthermore, since $f_j(X) \mid h(X)$, there exists a polynomial $h_1(X)$ such that $h_1(X) \cdot h(X) \equiv 1 \pmod{f_j(X)}$. Then $(g(X) \cdot h_1(X))^2 \equiv -1 \pmod{f_j(X)}$.

If F' is the extension of F obtained by adjoining a root of $f_j(X)$ to F then this last equation says that F' contains i. But this is a contradiction since F' contains p^{nk} elements with $p \equiv 3 \pmod 4$ and both n and k odd.

If $g(X)$ or $h(X)$ is divisible by $f_j(X)$ then, for some positive integer k, $f(X)=(f_j(X)^{2i}[(g'(X))^2+(h'(X))^2]$, where neither $g'(X)$ nor $h'(X)$ is divisible by $f_j(X)$. (Recall that an odd power of $f_j(X)$ divides $f(X)$, i.e. e_j was assumed to be odd.) Then, after dividing out by $(f_j(X))^{2i}$, one can repeat the above argument.

Thus, if $f(X)$ is a sum of two squares it is necessary that the irreducible factors of $f(X)$ of odd degree occur to even powers.

By virtue of the lemma and the identity

$$(x^2 + y^2)(z^2 + w^2) = (xz + yw)^2 + (xw - yz)^2,$$

in order to show that the conditions of the theorem are sufficient it suffices to show that any monic irreducible polynomial $f(X)\in F[X]$ of even degree can be written as a sum of two squares.

First let $f(X)$ be any monic irreducible polynomial in $F[X]$ and let F_1 be the extension of F obtained by adjoining i to F. Suppose $f(X)=p_1(X)p_2(X)\cdots p_s(X)$ is the factorization of f in $F_1[X]$ into monic irreducible polynomials. For any $g(X)\in F_1[X]$ denote by $\bar{g}(X)$ the conjugate polynomial obtained by replacing each coefficient $\alpha+\beta i$, $\alpha, \beta\in F$ of g by $\alpha-\beta i$. Then $f=\bar{f}=\bar{p}_1\bar{p}_2\cdots\bar{p}_s$. Multiplying these two factorizations of f together yields $f^2=(p_1\bar{p}_1)\cdots(p_s\bar{p}_s)$. Since f is irreducible and each $p_j\bar{p}_j\in F[X]$ there are only two possibilities: (i) $s=1$ and $f=p_1$ or (ii) $s=2$ and $f=p_1\bar{p}_1$. Thus any monic irreducible polynomial in $F[X]$ either remains irreducible in $F_1[X]$ or splits into a product of two irreducible polynomials which are conjugate over F.

Now suppose that $f(X)\in F[X]$ is a monic irreducible polynomial of even degree k. Let F' be the field obtained by adjoining a root of f to F. The order of F' is p^{nk}. Since nk is even F' contains i and therefore the equation $(g(X))^2\equiv -1 \pmod{f(X)}$ is solvable for $f(X)\in F[X]$. It follows that $f(X)$ could not remain irreducible in $F_1[X]$; for otherwise one would have either

$$f(X) \mid (g(X) + i) \quad \text{or} \quad f(X) \mid (g(X) - i)$$

in $F_1[X]$. But this is not possible. For example, if $g(X)+i=f(X)\cdot h(X)$ with $h(X)\in F_1[X]$, writing

$$h(X) = h_1(X) + ih_2(X) \quad \text{with} \quad h_j(X) \in F[X] \quad \text{for } j = 1, 2$$

leads to the impossible equation $f(X)\cdot h_2(X)=1$. Thus an irreducible polynomial $f(X)\in F[X]$ of even degree must split into a product of two conjugate polynomials in $F_1[X]$, i.e.

$$\begin{aligned} f(X) &= (g(X) + ih(X))\cdot(g(X) - ih(X)) \\ &= (g(X))^2 + (h(X))^2, \qquad g(X), h(X) \in F[X]. \end{aligned}$$

THE NUMBER OF k-SIMPLICES IN THE mth BARYCENTRIC SUBDIVISION OF AN r-SIMPLEX

D. G. HOEL, University of North Carolina, Chapel Hill

In this note some techniques from combinatorial probability are employed to determine the number $f(r, k, m)$ of k-simplices in the mth barycentric subdivision $\sigma^m A_r$ of the complex A_r consisting of an r-simplex together with its faces.

The problem reduces to studying the abstract complex $S=(A, \mathcal{P}(A))$ of which A_r is the geometric realization. Here $A=\{a_0, \cdots, a_r\}$ denotes the set of 0-simplices of A_r and $\mathcal{P}(A)$, the power set of A, is the set of (abstract) simplices of S. Following L. Bers ([1], p. 53), the barycentric subdivision σS of S is defined as follows: $\sigma S=(\mathcal{P}(A), L)$ where $L\subseteq\mathcal{P}(\mathcal{P}(A))$ and $\{S_{i_0}, \cdots, S_{i_j}\}\in L$ if and only if there exists a permutation of i, say k, such that $S_{k_0}\subseteq S_{k_1}\subseteq \cdots \subseteq S_{k_j}$. Thus $f(r, k, 1)$ is equal to the number of distinct collections $\{S_0, \cdots, S_k\}$ such that $S_0\subset S_1\subset \cdots \subset S_k$ where $S_i\in\mathcal{P}(A)$. Letting $E_0=S_0$, $E_i=S_i-S_{i-1}$ for $i=1, \cdots, k$ and $E_{k+1}=A-S_k$, we see that $f(r, k, 1)$ is equal to the number of distinct collections $\{E_0, \cdots, E_{k+1}\}$ where the sets $E_0, \cdots, E_{k+1}$ are pairwise disjoint and $E_0, \cdots, E_k$ are nonempty. Hence $f(r, k, 1)$ is equal to the number of ways of arranging $k+1$ balls (elements of A) in $k+2$ cells $(E_0, \cdots, E_{k+1})$ such that the first $k+1$ cells are not empty. Thus we have

$$f(r, k, 1) = N(r+1, k+2) + N(r+1, k+1), \tag{1}$$

where $N(r, k)$ denotes the number of ways of distributing r balls in k cells such that no cell is empty. Now it can be shown (see [2], p. 58) that

$$N(r, k) = \sum_{i=0}^{k} (-1)^i \binom{k}{i} (k-i)^r.$$

Thus, by (1),

$$\begin{aligned} f(r, k, 1) &= \sum_{i=0}^{k+1} (-1)^i \binom{k+2}{i} (k+2-i)^{r+1} + \sum_{i=0}^{k} (-1)^i \binom{k+1}{i} (k+1-i)^{r+1} \\ &= (k+2)^{r+1} + \sum_{i=1}^{k+1} (-1)^i \binom{k+2}{i} (k+2-i)^{r+1} \end{aligned}$$

$$
\begin{aligned}
&- \sum_{i=1}^{k+1} (-1)^i \binom{k+1}{i-1} (k+2-i)^{r+1} \\
&= (k+2)^{r+1} + \sum_{i=1}^{k+1} (-1)^i \binom{k+1}{i} (k+2-i)^{r+1} \\
&= \sum_{i=0}^{k+1} (-1)^i \binom{k+1}{i} (k+2-i)^{r+1}.
\end{aligned} \tag{2}
$$

Let b_{jk} denote the number of k-simplices of σA_j whose interior intersects the interior of A_j. Then we have

$$f(r, k, m) = \sum_{i=0}^{r} f(r, i, m-1) b_{ik}$$

and, by letting

$$F_m = \begin{bmatrix} f(0,0,m) & \cdots & f(0,r,m) \\ \vdots & & \vdots \\ f(r,0,m) & \cdots & f(r,r,m) \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} b_{00} & \cdots & b_{0r} \\ \vdots & & \vdots \\ b_{r0} & \cdots & b_{rr} \end{bmatrix},$$

we see that $F_m = F_{m-1}B$. Therefore, $F_m = F_0(F_0^{-1}F_1)^m$, where

$$f(i, j, 0) = \binom{i+1}{j+1}.$$

One notices that the general term of F_0^{-1} is $(-1)^{i+j}\binom{i}{j}$. Thus it is a matter of straightforward calculations similar to those in (2), to obtain

$$F_m = F_0 N^m,$$

where the general term of N is $N(i, j)$, which was defined above.

The author gratefully acknowledges the advice of Dr. I. M. Chakravarti and of Dr. M. E. Watkins, who posed this problem.

AN ALMOST-MEASURE OF SYMMETRY

R. L. TENNISON, University of Texas at Arlington

An *affine invariant measure of symmetry* [1, p. 234] is a real-valued function f defined on the family K^n of all convex bodies in E^n satisfying:
(1) $0 \leqq f(X) \leqq 1$ for all $X \in K^n$;
(2) $f(X) = 1$ if, and only if, X has a center of symmetry;

(3) $f(X)=f[t(X)]$ for every $X\in K^n$ and every nonsingular affine transformation t of E^n onto itself;
(4) $f(X)$ is a continuous function of X.

There are many examples of measures of symmetry which appear in the literature. (See [1], pages 245–51.) Among these is the Kovner-Besicovitch measure of symmetry [1, p. 254] which is of particular interest, and which is defined as follows.

For a convex body $X\in K^n$ and a point $p\in X$, let $X(p)=X\cap(2p-X)$, and let $F(X, p)$ be the ratio of the volumes of $X(P)$ and X. The Kovner-Besicovitch measure is then the maximal element of the set $\{F(X, p):p\in X\}$.

It is the purpose of this paper to introduce a function which has all the properties listed above except possibly that of continuity. For this reason, it is called an *almost-measure of symmetry*. The family K^n will be modified so that the singletons (i.e. sets consisting of a single point) will be treated as members of K^n.

The almost-measure of symmetry to be defined is different from most measures in that its origin is algebraic rather than geometric in nature. This almost-measure depends more on the symmetry of the summands of a given set than on the set itself.

For X and Y in K^n, $X+Y$ denotes the vector sum of X and Y. X and Y are called summands of $X+Y$. The *homothetic image* λX of X by the scalar λ is the set, $\{\lambda x:x\in X\}$. A set X is 0-symmetric if, and only if, $X=(-1)X$ and is symmetric if, and only if, there is a vector $x\in E$ such that $X-x$ is 0-symmetric. The vector x is called the *center of symmetry* of X.

Let $S(X)=\{Y: Y$ is a 0-symmetric summand of X and $Y\in K^n\}$. Clearly $S(X)\neq\varnothing$. Let $V(X)$ denote the n-dimensional Lebesgue measure of X and define $V^*(X)$ as sup $\{V(Y):Y\in S(X)\}$. The almost-measure of symmetry, f, is defined by

$$f(X) = V^*(X)/V(X),\ X\neq\{x\} \quad \text{and} \quad f(\{x\}) = 0.$$

An immediate consequence of this definition is that $0\leqq f(X)\leqq 1$ for each $X\in K^n$.

Suppose that X has a center of symmetry x. Then $X=(X-x)+x$ with $X-x\in S(X)$ and $V^*(X)=V(X-x)=V(X)$ which implies that $f(X)=1$. Note that not both summands are necessarily in K^n, unless modified.

Conversely, suppose that $X\in K^n$ with $f(X)=1$. It will be shown by a sequence of lemmas that X is symmetric. The proof uses the topology of K^n induced by the Hausdorff metric,

$$\Delta(X, Y) = \inf\{\lambda:X\subset Y+\lambda B \text{ and } Y\subset X+\lambda B\},$$

where B denotes the n-dimensional unit ball.

LEMMA 1. *For each $X\in K^n$, $S(X)$ is convex. That is, if Y_1 and $Y_2\in S(X)$ and $0\leqq\lambda\leqq 1$, then $\lambda Y_1+(1-\lambda)Y_2\in S(X)$.*

Proof. There exist sets Z_1 and Z_2 such that $X=Y_1+Z_1=Y_2+Z_2$. Therefore

$$X = \lambda X + (1-\lambda)X = \lambda(Y_1 + Z_1) + (1-\lambda)(Y_2 + Z_2)$$
$$= (\lambda Y_1 + (1-\lambda)Y_2) + (\lambda Z_1 + (1-\lambda)Z_2)$$

which proves the lemma.

LEMMA 2. *For each* $X \in K^n$, $S(X)$ *is a closed set.*

Proof. Any convergent sequence $\{X_n\}$ of 0-symmetric sets has a 0-symmetric limit. Now, if Y_0 is a limit point of $S(X)$, then there is a sequence $\{Y_n\}$ with $Y_n \in S(X)$ for each n which converges to Y_0, and corresponding to each Y_n there is a summand Z_n. Therefore $X = Y_n + Z_n = Y_0 + Z_0$ implies that $Y_0 \in S(X)$.

LEMMA 3. *For each* $X \in K^n$ *there exists a* $Y \in S(X)$ *such that* $V^*(X) = V(Y)$.

Proof. If $S(X)$ is finite then the theorem is true since $V^*(X)$ is simply the maximum of a finite set of real numbers. Otherwise a sequence $\{Y_n\}$ may be selected from $S(X)$ with the properties that $V(Y_i) < V(Y_j)$ for $i<j$ and $\lim V(Y_n) = V^*(X)$. By the Blaschke Selection Theorem [2, p. 64] there is a subsequence $\{Y_{n'}\}$ of $\{Y_n\}$ which has a limit in $S(X)$, say Y_0. Now $Y_{n'} \to Y_0$ and the continuity of the volume V imply that $V(Y_n) \to V(Y_0) = V^*(X)$, completing the proof.

LEMMA 4. *If* Y *and* Z *belong to* $S(X)$ *with* $V(Y) = V(Z) = V^*(X)$ *then* $Y = Z$.

Proof. The set $\frac{1}{2}Y + \frac{1}{2}Z \in S(X)$ by Lemma 1. Thus

$$V(\tfrac{1}{2}Y + \tfrac{1}{2}Z) \leqq V^*(X). \tag{1}$$

The Brunn-Minkowski inequality [2, p. 97] yields

$$[V(\tfrac{1}{2}Y + \tfrac{1}{2}Z)]^{(1/n)} \geqq \tfrac{1}{2}[V(Y)]^{(1/n)} + \tfrac{1}{2}[V(Z)]^{(1/n)} \tag{2}$$

with equality holding if, and only if, Y is a positive homothetic image of Z. But $V(Y) = V(Z) = V^*(X)$ and inequality (2) imply that

$$V(\tfrac{1}{2}Y + \tfrac{1}{2}Z) \geqq V^*(X). \tag{3}$$

By (1) and (3) Y and Z are positive homothetic images. But if Y and Z are both 0-symmetric and have the same volume then $Y = Z$.

THEOREM 1. *If* $f(X) = 1$ *then* X *is a nonzero symmetric set.*

Proof. $X \neq \{0\}$ since $f(0) = 0$. Now as $f(X) = 1$, $V^*(X) = V(X)$. Let Y be the unique element of $S(X)$ such that $V(Y) = V^*(X)$ and let Z be the corresponding summand. The Brunn-Minkowski inequality gives

$$[V(X)]^{(1/n)} \geqq [V(Y)]^{(1/n)} + [V(Z)]^{(1/n)}.$$

But $V(X) = V(Y)$ implies that equality must hold and therefore X must be a translate of a homothetic image of Y. Hence X is symmetric.

THEOREM 2. *If t is a nonsingular affine transformation from E^n onto itself then* $f(X)=f[t(X)]$.

Proof. If t is a simple translation then the theorem is true by the invariance of volume under a translation. Suppose then that t is a nonsingular linear transformation, and let $|\det t|$ denote the absolute value of the determinant of a matrix representation for t. Then $V[t(X)]=|\det t|\ [V(X)]$ and for each $Y\in S(X)$, $t(Y)\in S[t(X)]$ which imply that

$$f[t(X)] = V^*[t(x)]/V[t(x)] = |\det t|\ V^*(X)/|\det t|\ V(X) = f(X).$$

Hence f is affine invariant.

One shortcoming of this measure was pointed out by the referee, namely, it is sensitive only for a subclass of convex bodies closely related to symmetric bodies. Also, as has been indicated, the question of continuity relative to the Hausdorff metric was not settled.

A SERIES REPRESENTATION FOR EULER'S CONSTANT

A. W. ADDISON, Ohio State University

If we let γ denote Euler's constant, then

$$\gamma = \frac{1}{2} + \sum_{n=1}^{\infty} \sum_{m=2^{n-1}}^{2^n-1} \frac{n}{(2m)(2m+1)(2m+2)}.$$

Write $f(x)=-(x-[x])+\frac{1}{2}$, so that [1] if Re $s>0$, then

$$s\int_1^{\infty} \frac{f(x)}{x^{s+1}}\,dx = -\left(\frac{s}{s-1} - \zeta(s)\right) + \frac{1}{2}, \tag{1}$$

which for $s=1$ is equal to $\gamma-\frac{1}{2}$. Define

$$g(x) = f(x) - \frac{f(2x)}{2}, \tag{2}$$

so that

$$g(x) = \begin{cases} \frac{1}{4} & \text{if } 0 \leqq x-[x] < \frac{1}{2} \\ -\frac{1}{4} & \text{if } \frac{1}{2} \leqq x-[x] < 1. \end{cases} \tag{3}$$

In view of (2) we have $f(x)=\sum_{v=0}^{\infty} g(2^v x)/2^v$, so that for Re $s>0$

$$s\int_1^{\infty} \frac{f(x)}{x^{s+1}}\,dx = \sum_{v=0}^{\infty} \frac{1}{2^v}\, s\int_1^{\infty} \frac{g(2^v x)}{x^{s+1}}\,dx. \tag{4}$$

Write $y=2^{\nu}x$ in each integral within the summation sign of (4) so that (4) reduces to

$$\sum_{\nu=0}^{\infty} 2^{\nu(s-1)}s\int_{2^{\nu}}^{\infty}\frac{g(y)}{y^{s+1}}\,dy=\sum_{\nu=0}^{\infty}c_{\nu}(s)\cdot s\int_{2^{\nu}}^{2^{\nu+1}}\frac{g(y)}{y^{s+1}}\,dy, \tag{5}$$

where $c_{\nu}(s)=\sum_{k=0}^{\nu}2^{k(s-1)}$. Put $s=1$ in (5) and note that $c_{\nu}(1)=1+\nu$ so that

$$\int_{1}^{\infty}\frac{f(x)}{x^2}\,dx=\sum_{\nu=0}^{\infty}(1+\nu)\int_{2^{\nu}}^{2^{\nu+1}}\frac{g(y)}{y^2}\,dy,$$

But from (3) it follows that

$$\int_{m}^{m+1}\frac{g(y)}{y^2}\,dy=\frac{1}{4}\int_{m}^{m+\frac{1}{2}}\frac{dy}{y^2}-\frac{1}{4}\int_{m+\frac{1}{2}}^{m+1}\frac{dy}{y^2}=\frac{1}{(2m)(2m+1)(2m+2)},$$

from which the result follows easily.

A PROPERTY OF SYLOW SUBGROUPS OF FINITE GROUPS

H. S. Leonard, Jr., Carnegie Institute of Technology

Our purpose is to derive the following consequence of a theorem of Philip Hall [2, Theorem 14.4.1].

Theorem. *Let G be a finite group, p an odd prime, P a p-Sylow subgroup of G, N the normalizer of P, and H a subgroup of G containing N. Suppose G is generated by its elements of orders relatively prime to p. Suppose that P has a normal subgroup C of nilpotence class less than $p-1$. Suppose that for all $x\in G-H$, $C\not\subseteq x^{-1}Hx$. Then $P\subseteq H'$, the commutator subgroup of H.*

Remarks. Here H is its own normalizer in G, since H contains N. Hence the condition that $C\not\subseteq x^{-1}Hx$ means that H is the only conjugate of H containing C. The case of the theorem when C is abelian, and hence of class one, was formulated independently by J. G. Thompson in a letter to the author. The proof of this case is the essence of the proof of [1, Theorem 25.4], and, as pointed out to me by Professor Thompson, is contained in the proof of [1, Lemma 17.2]. The proof of the present theorem uses the same argument. For the concepts involved we refer to [2, pp. 207–211].

Proof. Suppose the hypotheses are satisfied and that $P\not\subseteq H'$. Then the group $u_p(H)$ generated by elements of H of orders relatively prime to p is a proper

GENERAL EXISTENCE CRITERIA FOR THE INVERSE OF AN OPERATOR

A. M. OSTROWSKI, University of Basel, Switzerland

It is well known that if S and T are two linear bounded operators on a Banach space B into B, and if S^{-1} exists on B, then the inequality

$$\|S - T\| < \frac{1}{\|S^{-1}\|} \tag{1}$$

implies the existence of T^{-1}.

In [1] it was noted that (1) can be replaced in the above statement by

$$\|(S - T)(I - T)\| < \frac{1}{\|S^{-1}\|}. \tag{2}$$

(See Theorem 3, pp. 273–274 of [1], where the condition is written in a different form obtained from the above replacing S by $I-S$ and T by $I-T$.)

In the following I prove the more general

THEOREM. *If S and T are two linear bounded operators on the Banach space B with their values in B, if S^{-1} exists on B and if for a polynomial $P(x)$ with $P(0) = 1$ we have*

$$\|S^{-1}(S - T)P(T)\| < 1, \tag{3}$$

then the left-sided inverse of T, T^{-1}, exists on B^*, the image of B by T, and is bounded on B^*.

Our condition contains for $P(x) \equiv 1$ the condition (1) and for $P(x) \equiv 1 - x$ the condition (2), since

$$\|S^{-1}(S - T)\| \leqq \|S^{-1}\| \, \|(S - T)\|,$$
$$\|S^{-1}(S - T)(I - T)\| \leqq \|S^{-1}\| \, \|(S - T)(I - T)\|.$$

Proof. By the assumption about $P(x)$ there exists a polynomial $Q(x)$ such that

$$P(x) - 1 = xQ(x). \tag{4}$$

Putting

$$U = S^{-1}(S - T)P(T), \tag{5}$$

we see from (3) that $(I-U)$ has an inverse on B, $(I-U)^{-1} = \sum_{\nu=0}^{\infty} U^{\nu}$.

(Cf. the comments on the use of the Liouville-Neumann series in this connection in [2], p. 4.) On the other hand it follows from (5) that, identically,

$$I - U = S^{-1}[T - (S - T)(P(T) - I)] = S^{-1}[I - (S - T)Q(T)]T$$

and, therefore, on B^* the left-sided inverse of T is

$$T^{-1} = (I - U)^{-1}S^{-1}[I - (S - T)Q(T)]. \tag{6}$$

From (6) we have further

$$\|T^{-1}\| \leqq \frac{1}{1-\|U\|}\|S^{-1}\|\,\|I-(S-T)Q(T)\|, \tag{7}$$

and we see that T^{-1} is bounded on B^*.

In applying the above theorem it is important to emphasize particularly the cases in which B^* is identical to B. This is certainly true if B is a finite dimensional space of dimension n and the operators S and T can be considered as $n\times n$ matrices. In this case, since the mapping of B on B^* by T is a one-to-one transformation, B^* must be identical to B and our theorem reads:

If S is a nonsingular matrix and (3) *is satisfied, then T is nonsingular, too.*

More generally this argument holds if the Fredholm alternative is valid for the mapping by T, for instance, if T or a power of T is compact. (Cf. the discussion of the conditions for the Fredholm alternative in [3].)

Obviously, by inverting the order of the factors in (3) we obtain the completely symmetric condition for the right-sided inverse.

Sponsored by the Mathematics Research Center, United States Army, Madison, Wisconsin, under Contract No.: DA-11-022-ORD-2059.

The author is grateful to Mr. Victor Pereyra of the MRC staff for helpful discussions.

PRIMARY ABELIAN GROUPS WITH A HEIGHT RESTRICTING CONDITION

H. E. HEATHERLY, Texas A & M University

The purpose of this paper is to consider primary abelian groups with a certain restriction on the height of the elements. This restriction, though not ruling out elements of infinite height, is sufficient to insure that any such group is the direct sum of cyclic groups or is divisible. Throughout the paper the word group will mean a p-primary abelian group.

DEFINITION. *A group G is said to be of contained height if and only if $h(x+y)\leqq h(x)+h(y)$ for each $x, y\in G$ such that $x+y\neq 0$. (Here $h(u)$ denotes the height of u in G.)*

LEMMA 1a. *If G is of contained height then every element of zero height has order p.*

Proof. If $h(y)=0$ and $py\neq 0$, we have

$1 \leqq h(py) = h[(p-1)y+y] \leqq h((p-1)y)+h(y) = 2h(y) = 0$, a contradiction.

LEMMA 1b. *If G is of contained height, every element of finite height has zero height.*

Proof. If $0 < h(x) = a < \infty$, we have $x = p^a y$, where $h(y) = 0$; by Lemma 1a, y has order p, so that $x = p^a y = 0$, a contradiction.

Thus in a group of contained height every element of finite height has zero height and order p.

Recall that a group G is reduced if and only if it has no divisible subgroups; a subgroup H of G is pure if and only if whenever $x \in H$ is divisible in G, then it is divisible in H.

LEMMA 2. *If G is reduced and of contained height, every nonzero element has zero height and order p.*

Proof. The set I of elements of G which have infinite height (in G) is a subgroup. If I is not pure, some nonzero $x \in I$ must have finite height a in I. But since x has infinite height in G, there exists $g \in G$, $g \notin I$, such that $p^{a+1}g = x$. Since $g \notin I$, it has finite height and we have

$$\infty = h(x) = h(p^{a+1}g) \leqq h((p^{a+1}-1)g)+h(g) = 2h(g) < \infty,$$

contradiction; hence I is pure. But then every element of I has infinite height in I, making I divisible; since G is reduced, this means that $I = (0)$. Thus every nonzero element of G has finite height and hence by Lemmas 1b and 1a the desired conclusion follows.

THEOREM 1. *If G is of contained height, it is either divisible or reduced.*

Proof. Write $G = D \oplus H$, where D is the maximal divisible subgroup of G and H is reduced. If H has no elements of finite height in G, then G has no elements of finite height. Either G has all elements of infinite height and hence is divisible or H has an element of finite height. We turn our attention to the case where G is not divisible. Suppose that D and H are each nontrivial. For any $z \in D$, $h(z) = \infty$; also there exists $x \in H$ such that $h(x) < \infty$, which by Lemma 1a and Lemma 1b implies that $h(x) = 0$ and x has order p. Then

$$\infty = h(z) = h((p-1)x+(x+z)) \leqq h((p-1)x)+h(x+z) = 0+0 = 0.$$

The supposition that both D and H are nontrivial is false and since G is not divisible we see that G is reduced.

It is well known that any group of bounded order is a direct sum of cyclic groups [2, Th. 6, pp. 17–18]. Instead of making use of this result the following special case will be proven in an elementary manner.

LEMMA 3. *If every element of G has order p, then G is a direct sum of cyclic groups.*

Proof. We say a subset $\{x_1, \cdots, x_n\}$ of G is linearly independent if and only if $a_1x_1+\cdots+a_nx_n=0$ implies $a_ix_i=0$, $i=1, \cdots, n$; an infinite subset A of G is linearly independent if and only if every finite subset of A is linearly independent. Let F be the set of all linearly independent subsets of G. Partially order F by set inclusion. Using Zorn's lemma we establish the existence of a maximal element M of F. Let $C(M)=\{T:T$ is a cyclic group generated by $x\in M\}$. Let $G'=\Sigma T$, where $T\in C(M)$. From the independence of M it follows that the sum is direct. Now suppose that $x\in G$, $x\notin G'$. Then $qx\notin G'$, where $0<q<p$. Consider $M\cup(x)$, where (x) is the subgroup generated by x. M is a proper subset of $M\cup(x)$. If $n_1x_1+\cdots+n_kx_k+nx=0$, where $0<n_i<p$, $0<n<p$, and $x_i\in M$, then $n_ix_i=nx=0$, for otherwise we would have $nx\in M$. Thus $M\cup(x)$ is linearly independent, contrary to the maximality of M. We see now that $G=G'=\Sigma T$, where the T are cyclic groups and the sum is direct.

COROLLARY. *If G is of contained height then it is either divisible or a direct sum of cyclic groups.*

Proof. By Theorem 1, if G is not divisible it is reduced; by Lemma 2, every nonzero element of G has zero height; by Lemma 1a, every element of G has order p, so that the desired conclusion follows from Lemma 3.

If the property of contained height is redefined so that $h(x+y)\leqq\theta_1h(x)+\theta_2h(y)$ where $0<\theta_1<\infty$ and $0<\theta_2<\infty$, then the above results still hold and the proofs remain essentially the same.

A k-CRITICAL GRAPH OF GIVEN DENSITY

L. C. HOUSE, University of Connecticut

In this note a *graph* is a pair (G, E) where G is a finite set and E is a set of unordered pairs of distinct elements of G. The elements of G are called *vertices* and those of E *edges*. We will refer to the graph simply by G if the edge set is clear by the context. Graphs which are isomorphic by an obvious definition will not be distinguished. The notation xEy (or yEx) will be used to abbreviate $\{x, y\}\in E$. Also $E(x)=\{y\in G:xEy.\}$ A *subgraph of* (G, E) is a graph (H, F) with $H\subseteq G$ and $F\subseteq E$.

A subset A of G is called *independent* if and only if xEy is false for every x, $y\in A$. A *k-coloring of G* is a partition $\mathfrak{C}$ of G into k cells $A_1, A_2, \cdots, A_k$ where each A_i is independent. The indices 1, 2, $\cdots$ k are the "colors" and vertices x

and y "have the same color (in $\mathfrak{A}$)" means that they belong to the same cell. The *chromatic number of* G is the smallest positive integer $k(G)$ such that there exists a $k(G)$-coloring of G.

A graph is called a *complete graph on n vertices* and designated $\{n\}$ if $|\{n\}| = n$ and xEy for all distinct $x, y \in \{n\}$. The *density of* G is the largest positive integer $d(G)$ such that G has $\{d(G)\}$ as a subgraph. For any graph it is clear that $k(G) \geqq d(G)$.

A graph (G, E) is called a *k-critical graph* if and only if $k(G) = k$ and whenever (H, F) is a subgraph of (G, E) such that either H is a proper subset of G or F is a proper subset of E then $k(H) < k$. Clearly $\{k\}$ is a k-critical graph since whenever any edge $\{x, y\}$ is removed there exists a $(k-1)$-coloring of G in which x and y have the same color.

Zykov [1] has shown that for any positive integers d and k with $1 < d \leqq k$ there exists a graph G with $d(G) = d$ and $k(G) = k$. The purpose of this note is to show how we may construct a k-critical graph of density d. The construction also requires fewer vertices than Zykov's—(11 for a 4-critical graph of density two as compared to 140 in the Zykov construction, for example).

If $\mathfrak{A} = \{A_1, A_2, \cdots, A_k\}$ is a k-coloring of G and $x \in A_i$ then x is called *complete* (mod $\mathfrak{A}$) if and only if $E(x) \cap A_j \neq \varnothing$ for all $A_j \in \mathfrak{A}$ with $j \neq i$.

LEMMA 1. *Let $k(G) = k$ and $\mathfrak{A}$ be a k-coloring of G. Then for each $i = 1, 2, \cdots, k$ there exists a vertex $x \in A_i$ that is complete* (mod $\mathfrak{A}$).

Proof. Suppose that for some A_i no such vertex exists. Then any vertex in A_i can be replaced (recolored) in another cell of $\mathfrak{A}$ to produce a new coloring $\mathfrak{A}'$ in which A_i still has no complete vertex. Repeating this process eventually leads to a $k-1$ coloring of G.

LEMMA 2. *If (G, E) is k-critical and xEy then there exists a k-coloring of G in which no other vertex in G has the same color as x and no other vertex in $E(x)$ has the same color as y.*

Proof. If we remove $\{x, y\}$ from E we may color the resulting graph in $k-1$ colors. In such a coloring x and y will necessarily be the same color since otherwise the same coloring would suffice for the original graph G. We may thus recolor x using a kth color and reinsert $\{x, y\}$ to obtain the desired coloring.

THEOREM. *Given any positive integers d and k with $1 < d \leqq k$ there exists a k-critical graph of density d.*

Proof. We first note that for $d = k$ the complete graph on k vertices will suffice. The theorem is thus proved by showing that the construction is possible for the integers d and $k+1$ if it is possible for d and k. Thus, assume that (G, E) is a k-critical graph of density d. We also assume that G has r vertices.

We construct the graph (G', E') as follows. Let $G = \{g_1, g_2, \cdots, g_r\}$ and select r more vertices $X = \{x_1, x_2, \cdots x_r\}$ disjoint from G, and a final vertex z not in either G or X. Let $G' = G \cup X \cup \{z\}$. E' is defined by the rules $x_i E' g_j$ and

$g_iE'g_j$ whenever g_iEg_j and also $zE'x_i$ for each $x_i \in X$. Note that X is independent in G'.

Clearly $k(G') \geqq k$. To show that $k(G') = k+1$ we first note that a $k+1$ coloring exists by using any k-coloring of G, then coloring x_i the same as g_i and using a $(k+1)$st color on z. Thus we need only show that G' cannot be colored in k colors. But this is clear since any k-coloring of G' determines a k-coloring of G and, by Lemma 1, for each color there exists a complete vertex of that color considering only the vertices in G. If g_i is complete then x_i must have the same color. Thus all k colors are used for the vertices of X and there is no color remaining for z.

To show that G' is k-critical we consider three cases: (i) the removal of an edge connecting two vertices of G, (ii) the removal of any edge having z as one end point, and (iii) the removal of any edge connecting a vertex in G with a vertex in X. In each of these cases the remaining graph can be colored in k colors. In case (i) we can color the vertices of G in $k-1$ colors and the vertices of X in the same $k-1$ colors (by coloring x_i the same as g_i) and then a kth color for z. In case (ii) if $\{z, x_i\}$ is removed then, using only part of Lemma 2, we can color the vertices of G in k colors in such a way that no other vertex in G has the same color as g_i. The vertices of X may then be colored correspondingly so that no other vertex of X has the same color as x_i. Then z may be colored the same as x_i. In case (iii) suppose $\{x_i, g_j\}$ is removed. By Lemma 2 we may color the vertices of G with k colors in such a way that no other vertex in G has the same color as g_i and no other vertex of $E'(g_i) \cap G$ has the same color as g_j. Then the vertices of X may be colored the same as the corresponding colors of G except for x_i which is colored the same as g_j. Thus only $k-1$ colors are used on the vertices of X and z may be colored by the remaining color.

To show that $d(G') = d(G)$ where $d(G) > 1$ we note that clearly $d(G') \geqq d(G)$. If $d(G') > d(G)$ then $d(G') \geqq 3$ and there must exist a complete subgraph $\{m\}$ of G' with $m \geqq 3$, and $m > n$ for any complete subgraph $\{n\}$ of G. Clearly z is not a vertex of $\{m\}$ and no two vertices of X belong to $\{m\}$. Since the vertices of $\{m\}$ cannot all belong to G there must be one vertex x_i of X in $\{m\}$ and $m-1$ vertices from G. But then if x_i were replaced by g_i the resulting graph would be a complete $\{m\}$ in the original graph G. This contradiction completes the proof.

We note in particular that when we commence with a pentagon and repeat the above construction we can construct a critical k-chromatic graph without triangles having $(2^{k-3} \cdot 6) - 1$ vertices. An interesting question posed by Ore [2] is what is the minimum number of vertices in such a graph.

ON THE NUMERICAL RADIUS OF A LINEAR OPERATOR

J. P. WILLIAMS and T. CRIMMINS, Institute of Science and Technology, University of Michigan

If T is a bounded linear operator on a complex Hilbert space $\mathfrak{H}$ the *numerical range* of T is defined [1] as

$$W(T) = \{(Tf, f) \mid f \in \mathfrak{H}, \|f\| = 1\},$$

and the *numerical radius* $|W(T)|$ is given by

$$|W(T)| = \sup_{\lambda \in W(T)} |\lambda|.$$

It is well known that $\frac{1}{2}\|T\| \leqq |W(T)| \leqq \|T\|$. It is also well known that these inequalities are the best possible. Equality on the right holds for any normal operator, the simplest example being an operator on a 1-dimensional Hilbert space. The simplest operator for which $|W(T)| = \frac{1}{2}\|T\|$ is the "2-dimensional shift" given by the matrix

$$S_2 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

It is easy to show that if T is any operator on a Hilbert space such that $|W(T)| = \|T\| = 1$, and which attains its numerical radius, then there exists a 1-dimensional reducing subspace for T. We prove the analogous result:

THEOREM. *If* $|W(T)| = \frac{1}{2}$ *and* $\|T\| = 1$ *and* T *attains its norm, then there exists a 2-dimensional reducing subspace on which* T *is the 2-dimensional shift.*

Proof. By assumption, there is $f_1 \in \mathfrak{H}$ such that $\|Tf_1\| = \|f_1\| = 1$. Let $f_2 = Tf_1$. Then

$$(T^*f_2, f_1) = (f_2, Tf_1) = \|f_2\|^2 = 1.$$

Since $\|T^*\| \leqq 1$, this implies $T^*f_2 = f_1$.

For any operator A, $([\mathrm{Re}\, A]f, f) = \mathrm{Re}\,(Af, f)$ and therefore, since $\mathrm{Re}\, A$ is self-adjoint,

$$\|\mathrm{Re}\, A\| = |W(\mathrm{Re}\,[A])| \leqq |W(A)|.$$

Thus,

$$\|\mathrm{Re}[e^{i\theta}T]\| \leqq |W(e^{i\theta}T)| = |W(T)| = \tfrac{1}{2}.$$

In particular,

$$\|e^{i\theta}Tf_2 + e^{-i\theta}T^*f_2\|^2 \leqq 1,$$
$$\|Tf_2\|^2 + 2\,\mathrm{Re}[e^{2i\theta}(Tf_2, T^*f_2)] + \|T^*f_2\|^2 \leqq 1,$$
$$\|Tf_2\|^2 \leqq -2\,\mathrm{Re}[e^{2i\theta}(Tf_2, T^*f_2)]$$

for all θ. Hence $Tf_2 = 0$. Similarly, the inequality

$$\|e^{i\theta}Tf_1 + e^{-i\theta}T^*f_1\|^2 \leqq 1$$

implies that $T^*f_1 = 0$. Furthermore,

$$(f_1, f_2) = (f_1, Tf_1) = (T^*f_1, f_1) = 0.$$

Let $\mathfrak{M}$ be the subspace spanned by f_1 and f_2. Then $\mathfrak{M}$ reduces T and the matrix of $T|M$ relative to the basis $\{f_1, f_2\}$ is S_2.

As a corollary, note that the theorem yields a characterization of the 2-dimensional shift, namely, it is the only operator which is irreducible, has numerical radius $\frac{1}{2}$, norm 1 and which attains its bound.

In conclusion we point out that it is easy to construct counterexamples to show that the hypothesis that T attains its bound cannot be omitted.

A CONTINUOUS PERIODIC FUNCTION HAS EVERY CHORD TWICE

J. B. Diaz and F. T. Metcalf, Institute for Fluid Dynamics and Applied Mathematics, University of Maryland

A continuous periodic function has horizontal chords of all lengths; that is, if the real valued continuous function f, defined for all real x, has period $p>0$, and a is any real number, then there is at least *one* x such that $f(x+a)-f(x)=0$. The proof given in [1, p. 78] consists of two parts. It is shown there that: (1) the function $f(x+a)-f(x)$ must "change sign" (unless f also has the period a, when there is no more to be said) and (2) if $f(x+a)-f(x)$ "changes sign once in a period it must change sign at least twice," which means, actually, that Boas proves the numerically stronger result (3) f "has *two* horizontal chords of any given length, with their left-hand endpoints at different points of $[0, p)$." While the proof of (2) is elementary, based only on the intermediate value property of continuous functions, the proof of (1) involves the extraneous notions of Riemann integration and change of variable in an integral, plus the fact that if a definite integral vanishes, the continuous integrand must be identically zero or it must "change sign."

It is the purpose of this note to present an alternative direct proof of (3), based upon the precise meaning of the phrase "changes sign," which has the same elementary character as the proof of (2) just mentioned, and resembles the proof of the "universal chord theorem" [1, p. 79].

Given a, either the function $f(x+a)-f(x)$ "changes sign" or it does not "change sign." If the function $f(x+a)-f(x)$ "changes sign" (i.e., it is >0 for one value of x and <0 for another value of x) then (3) follows from the intermediate value property of continuous functions, as in the argument for (2) mentioned above. On the other hand, if $f(x+a)-f(x)$ does not "change sign," it may be supposed, without loss, that $f(x+a)-f(x)\geqq 0$ for *all* x. Let n_i and m_i,

where $m_i \geqq 1$ and $i=1, 2, 3, \cdots$, be integers such that $\lim_{i\to\infty}(m_i a - n_i p) = 0$. The existence of these integers follows, in a known way, from the elements of Diophantine approximation, by means of the "Dirichlet box principle." (Let i be a positive integer, and consider the $i+1$ differences

$$k\frac{a}{p} - \left[k\frac{a}{p}\right], \quad \text{for } k = 0, 1, 2, \cdots, i;$$

where, as usual, $[y]$ denotes the integer such that $[y] \leqq y < [y]+1$. These $i+1$ differences all belong to the interval $[0, 1)$. Therefore, at least two of them must belong to one of the i subintervals (each of length $1/i$): $[0, 1/i)$, $[1/i, 2/i)$, $\cdots$, $[(i-1)/i, 1)$; that is,

$$\left| k_1\frac{a}{p} - \left[k_1\frac{a}{p}\right] - \left(k_2\frac{a}{p} - \left[k_2\frac{a}{p}\right]\right)\right| < \frac{1}{i},$$

where, without loss, $k_1 > k_2$, say. Then one can choose $m_i = k_1 - k_2 \geqq 1$ and

$$n_i = \left[k_1\frac{a}{p}\right] - \left[k_2\frac{a}{p}\right],$$

to obtain the inequality $|m_i a - n_i p| < p/i$.) Then, for any x, one has

$$0 \leqq f(x+a) - f(x) \leqq \sum_{k=1}^{m_i} [f(x+ka) - f(x+(k-1)a)]$$
$$= f(x+m_i a) - f(x) = f(x+m_i a - n_i p) - f(x).$$

Therefore, by the continuity of f at x, it follows (upon letting i tend to ∞) that $f(x+a) - f(x) \equiv 0$, so that (3) again holds.

It follows immediately from (3) *alone* (with $\Delta^{n-1}f$ taking the place of f) that the nth order difference $\Delta^n f(x) = \Delta \cdot \Delta^{n-1} f(x)$, where $\Delta f(x) = f(x+a) - f(x)$ and $n = 2, 3, \cdots$, vanishes at least *twice* in $0 \leqq x < p$. (See [1, p. 79 and p. 174] for another argument, using integration, when $n=2$.)

Suppose now, instead, that f is merely a real-valued function, defined for all real x, having period $p>0$; and that a is any real number. The argument given above shows that either: (a) the function $f(x+a) - f(x)$ changes sign (since now f need not be continuous, it cannot be concluded that the difference $f(x+a) - f(x)$ must change sign more than once); or (b) the function $f(x+a) - f(x)$ vanishes at every x where f is continuous. Therefore, if one supposes, in addition, that: (a) the difference function $f(x+a) - f(x)$ is a Darboux function (i.e., this function always assumes every real value which lies between any two of its values); (b) f is continuous for at least one x; then one can conclude that f has at least *one* chord of length a.

UNIQUENESS IN THE DIVISION ALGORITHM

M. A. JODEIT, JR., Rice University

The division algorithm for polynomials with coefficients in a field gives unique quotient and remainder. This note shows that such uniqueness characterizes polynomial rings among Euclidean domains.

An integral domain E which admits an integral-valued function g satisfying the following two conditions is called a *Euclidean domain* ([1], Section 18):

(1) $g(ab) \geqq g(a) \geqq 0$ for all $a \neq 0 \neq b$;

(2) For each $a \neq 0$ and b in E there exist q, r such that

$$b = qa + r, \qquad r = 0 \quad \text{or} \quad g(r) < g(a).$$

Quotient and remainder are *unique* if only one pair q, r satisfies (2) for given a, b. We recall these results from [1]: Each Euclidean domain has an identity 1; $g(a) < g(b)$ if a is a proper divisor of b; $g(a) = g(1)$ iff a is a unit.

THEOREM. *Let E be a Euclidean domain in which $1 \neq 0$. If quotient and remainder in E are unique the units (with zero) form a field F; if $E \neq F$, $E \cong F[x]$.*

The main point is contained in

LEMMA 1. *Quotient and remainder are unique iff* $g(a + b) \leqq \max(g(a), g(b))$.

Proof. If $a \neq 0 \neq b$ are such that $g(a + b) > \max(g(a), g(b))$, then

$$\begin{aligned} a &= 0(a + b) + a, & g(a) &< g(a + b), \\ &= 1(a + b) - b, & g(b) &< g(a + b). \end{aligned}$$

This contradicts uniqueness.

If the inequality holds and

$$\begin{aligned} c &= qa + r, & r &= 0 \quad \text{or} \quad g(r) < g(a), \\ &= q'a + r', & r' &= 0 \quad \text{or} \quad g(r') < g(a), \end{aligned}$$

with $r \neq r'$ and $q \neq q'$, then

$$g(a) \leqq g((q - q')a) = g(r' - r) < g(a).$$

Thus $r = r'$ or $q = q'$. Since either of these implies the other, uniqueness holds.

In what follows we may assume that $g(1) = 0$; if not let $g'(a) = g(a) - g(1)$; g' has all the other properties of g.

To see that the set F of units, with zero added, is a field, it is enough to show that a nonzero sum of units is a unit, and this follows from

$$0 \leqq g(u_1 + u_2) \leqq \max(g(u_1), g(u_2)) = g(1) = 0.$$

Finally, if $E \neq F$ we must find an isomorphism $E \to F[x]$. This comes from

LEMMA 2. *If $a \neq 0$ is such that $g(a)$ is a positive minimum, for each $0 \neq b \in E$ there exist unique $q_0, \cdots, q_k$ in F such that*

$$b = q_k a^k + \cdots + q_1 a + q_0, \qquad q_k \neq 0.$$

Then the mapping $b \to \sum q_j x^j$ is an isomorphism.

Proof. The sequence $g(a^k)$, $k = 0, 1, \cdots$ is strictly increasing since a^k is a proper divisor of a^{k+1}.

If $b \neq 0$, $g(a^k) \leqq g(b) < g(a^{k+1})$ for some $k \geqq 0$. Then $b = q_k a^k + r$, $r = 0$ or $g(r) < g(a^k)$. $q_k \neq 0$; if q_k were not a unit we would have

$$q_k = la + m, \qquad m \in F \quad \text{and} \quad l \neq 0.$$

By Lemma 1, $g(b) \geqq g(b - ma^k - r) = g(la^{k+1}) \geqq g(a^{k+1})$, contrary to assumption.

If $r \neq 0$, we apply the argument again. By induction

$$b = \sum_{j=0}^{k} q_j a^j, \qquad q_j \in F. \tag{3}$$

Finally, if $0 = \sum_{j=m}^{n} s_j a^j$, $s_j \in F$, $s_m \neq 0$, we have

$$-s_m = a\left(\sum_{j=m+1}^{n} s_j a^{j-m-1}\right)$$

which implies $g(1) \geqq g(a)$, and contradicts the choice of a. Thus all the s_j are zero. It follows that the representation (3) is unique.

The author wishes to thank the referee for his comments.

A NOTE ON A CONVOLUTION-TYPE COMBINATORIAL IDENTITY

MICHAEL SKALSKY, Southern Illinois University

Using the results developed in a series of papers, H. W. Gould [2] proved the following identity

$$\sum_{k=0}^{n} (-1)^k A_k(c, tb) A_{n-k}(a + bk - k, (1 - t)b) = A_n(a - c, (1 - t)b), \tag{1}$$

where

$$A_k(a, b) = \frac{a}{a + bk}\binom{a + bk}{k}.$$

The identity (1) is valid for any numbers a, b, c, t, and for $a=c$ reduces to an orthogonality relation

$$\sum_{k=0}^{n} (-1)^k A_k(a, tb) A_{n-k}(a + bk - k, (1 - t)b) = \binom{0}{n}.$$

The purpose of this note is to derive (1) directly by use of Lagrange's formula for the inversion of power series. We state without proof Lagrange's formula [1]:

If $w=f(z)=z/\phi(z)=\sum_{n=1}^{\infty} a_n z^n$ is an analytic function, regular in a neighborhood of the point $z=0$, and satisfying the condition $a_1=f'(0)\neq 0$, then the equation $f(z)=w$ has a unique solution, regular in a neighborhood of the point $w=0$ of the form

$$z = g(w) = \sum_{n=1}^{\infty} \frac{w^n}{n!}\left[\frac{d^{n-1}}{dz^{n-1}}(\phi(z))^n\right]_{z=0}.$$

More generally, if $F(z)$ is an analytic function regular in a neighborhood of the point $z=0$, then there is a neighborhood of the point $w=0$ in which

$$F(z) = F(0) + \sum_{n=1}^{\infty} \frac{w^n}{n!}\left[\frac{d^{n-1}}{dz^{n-1}}(F'(z)\{\phi(z)\}^n)\right]_{z=0}. \tag{2}$$

With (2) given, the proof of (1) becomes simple. Choosing $\phi(z)=(1+z)^{tb}$, and $F(z)=(1+z)^c$, where b, c, t are any complex numbers, and applying (2), we obtain

$$\begin{aligned}(1 + z)^c &= 1 + \sum_{k=1}^{\infty} \frac{w^k}{k!}\left[\frac{d^{k-1}}{dz^{k-1}}\{c(1 + z)^{c-1}(1 + z)^{tbk}\}\right]_{z=0} \\ &= 1 + \sum_{k=1}^{\infty} c\frac{w^k}{k!}(c + tbk - 1)_{k-1} = \sum_{k=0}^{\infty} w^k \binom{c + tbk}{k}\frac{c}{c + tbk} \\ &= \sum_{k=0}^{\infty} w^k A_k(c, tb),\end{aligned} \tag{3}$$

where $w=z/(1+z)^{tb}$.

Replacing in (3) $1+z$ by $(1+z)^{-1}$ we get

$$(1 + z)^{-c} = \sum_{k=0}^{\infty} (-1)^k A_k(c, tb) z^k (1 + z)^{tbk-k}. \tag{4}$$

Multiplying both sides of (4) by $(1+z)^a$ we obtain

$$\begin{aligned}(1 + z)^{a-c} &= \sum_{k=0}^{\infty} (-1)^k A_k(c, tb) z^k (1 + z)^{a+tbk-k} \\ &= \sum_{k=0}^{\infty} (-1)^k A_k(c, tb)[z/(1 + z)^{b-tb}]^k (1 + z)^{a+bk-k}.\end{aligned} \tag{5}$$

Using (2) once more, with $F(z)=(1+z)^{a+bk-k}$ and $\phi(z)=(1+z)^{b-tb}$, we get from (5)

$$(1+z)^{a-c}=\sum_{k=0}^{\infty}(-1)^k A_k(c,tb)\left[z/(1+z)^{b-tb}\right]^k$$

$$\cdot\sum_{j=0}^{\infty}A_j(a+bk-k,\,b-tb)\left[z/(1+z)^{b-tb}\right]^j \tag{6}$$

$$=\sum_{k=0}^{\infty}\sum_{j=0}^{\infty}(-1)^k A_k(c,tb)A_j(a+bk-k,\,b-tb)v^{k+j},$$

where $v=z/(1+z)^{b-tb}$. Letting $k+j=n$, we find from (6)

$$(1+z)^{a-c}=\sum_{n=0}^{\infty}v^n\sum_{k=0}^{n}(-1)^k A_k(c,tb)A_{n-k}(a+bk-k,\,b-tb). \tag{7}$$

On the other hand, the application of (2) with $F(z)=(1+z)^{a-c}$ and $\phi(z)=(1+z)^{b-tb}$ yields

$$(1+z)^{a-c}=\sum_{n=0}^{\infty}v^n A_n(a-c,\,b-tb). \tag{8}$$

Equating the coefficients of v^n in (7) and (8), we obtain

$$\sum_{k=0}^{n}(-1)^k A_k(c,tb)A_{n-k}(a+bk-k,\,b-tb)=A_n(a-c,\,b-tb).$$

ON A THEOREM OF H. PÉTARD

CHRISTIAN ROSELIUS, Tulane University

In a classical paper [4], H. Pétard proved that it is possible to capture a lion in the Sahara desert. He further showed [4, no. 8, footnote] that it is in fact possible to catch every lion with at most one exception. Using completely new techniques, not available to Pétard at the time, we are able to sharpen this result, and to show that *every* lion may be captured.

Let $\mathfrak{L}$ denote the category whose objects are lions, with "ancestor" as the only nontrivial morphism. Let $\mathfrak{l}$ be the category of caged lions. The subcategory $\mathfrak{l}$ is clearly complete, is nonempty (by inspection), and has both a generator and cogenerator [3, vii, 15–16]. Let $F\colon \mathfrak{l}\to\mathfrak{L}$ be the forgetful functor, which forgets the cage. By the Adjoint Functor Theorem [1, 80–91] the functor F has a coadjoint $C\colon \mathfrak{L}\to\mathfrak{l}$, which reflects each lion into a cage.

We remark that this method is obviously superior to the Good method [2], which only guarantees the capture of one lion, and which requires an application of the Weierkäfig Preparation Theorem.

ON (WHAT SHOULD BE) A WELL-KNOWN THEOREM IN GEOMETRY

DANIEL PEDOE, University of Minnesota

The following theorem is not as well known as it should be:

(a) *If ABC is a given triangle, V a point in the plane of ABC which does not lie on a side of the triangle, and $A'B'C'$ is a triangle which has $B'C'$ parallel to VA, $C'A'$ parallel to VB and $A'B'$ parallel to VC, then lines through A' parallel to BC, through B' parallel to CA and through C' parallel to AB will be concurrent at a point V'.*

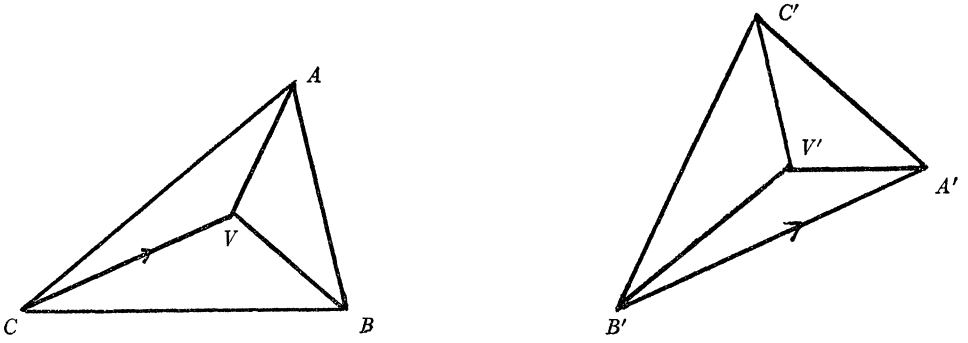

FIG. 1

The theorem is, however, more familiar to geometers in the form:

(b) *If ABC and $A'B'C'$ are two triangles which are such that lines through A*

parallel to $B'C'$, through B parallel to $C'A'$ and through C parallel to $A'B'$ meet in a point V, then the lines through A', B' and C' parallel to BC, CA and AB respectively will also meet in a point V'.

It is in this second form that this theorem appears as an exercise in the older books on coordinate geometry. There is a tendency for this theorem to be rediscovered from time to time. It has a respectable history, and is at least a hundred years old. It should be better known, perhaps.

In the form (a) it can be found in books on statics. The quadrangles $ABCV$, $A'B'C'V'$ are said to form *reciprocal figures*, and the interesting thing about the two figures is that in any one figure three lines forming the sides of a triangle are parallel to three concurrent lines in the other.

The connection with graphical statics is evident, to anyone who has studied force-diagrams. To quote Clerk Maxwell (Philosophical Magazine, (1864), p. 258): "If forces represented in magnitude by the lines of the first figure be made to act between the extremities of the corresponding lines of the reciprocal figure, then the points of the reciprocal figure will all be in equilibrium under the action of these forces."

This statement refers to general reciprocal figures. Not every figure of straight lines and points in the plane admits a reciprocal figure. Maxwell obtained his general reciprocal figures by the orthogonal projection of polyhedra reciprocal with respect to a paraboloid of revolution. After the projection, one figure has to be rotated through a right angle. The great Italian geometer Cremona, who published a book called *Reciprocal figures in graphical statics* (Oxford, 1890), preferred to use polyhedra reciprocal with respect to a null system, on the grounds that after a suitable projection the reciprocal figures were produced without one having to be rotated through a right angle!

Clerk Maxwell's early papers were on geometry, and a knowledge of elementary geometry does not seem to have hurt him! It is interesting to see how he proves Theorem (a). He considers circles with centers at the points A, B, C and V and notes that the chord of intersection of two circles is perpendicular to the line joining the centers and the chords of intersection of three circles, taken in pairs, all pass through a point. Hence the common chords of the four circles are six lines which pass in threes through four points A', B', C' and V', where $B'C' \perp VA$, $C'A' \perp VB$, $A'B' \perp VC$, $V'A' \perp BC$, $V'B' \perp CA$ and $V'C' \perp AB$. All we have to do now is to rotate the figure $A'B'C'V'$ through a right angle, and the figure reciprocal to $ABCV$ is in existence!

This involvement with right angles suggests another theorem, which also appears in books on coordinate geometry:

(c) *If the perpendiculars from the vertices A, B and C of a triangle ABC onto the sides $B'C'$, $C'A'$ and $A'B'$ of a triangle $A'B'C'$ are concurrent, then so are the perpendiculars from the vertices A', B' and C' of $A'B'C'$ onto the sides BC, CA and AB of triangle ABC.*

This theorem can be found in Steiner (Gesammelte Werke, 1 (1881) p. 157, G. Reimer, Berlin), but it is immediately derived from Theorem (b). Rotate the triangle $A'B'C'$ through a right angle. If it be called $A^*B^*C^*$ in its new position, we are told that lines through A, B and C parallel to B^*C^*, C^*A^* and A^*B^* respectively meet in a point V^*. Hence lines through A^*, B^* and C^* respectively parallel to BC, CA and AB will be concurrent in a point V. Rotate $A^*B^*C^*$ back to $A'B'C'$, and let V' be the new position of V. Then lines through A', B' and C' perpendicular to BC, CA and AB respectively intersect at V'.

To make the theorem apparently harder, we can rotate the triangle $A'B'C'$ through an angle α. The formulation of the theorem can be left to the student. Rotation brings relief, in any case.

There are a number of different proofs of (a), not as ingenious as Maxwell's proof. That version of Ceva's theorem which introduces the ratio of the sines of the angles which VA, VB and VC make with the sides of triangle ABC gives an immediate proof on rearrangement, since the Ceva condition for concurrency is also a sufficient condition. But a more fundamental proof can be given if we use projective geometry.

The six sides of the quadrangle $ABCV$ intersect any line in the plane in three pairs of points in involution, and this is also true if the line be the line at infinity. Let the intersections with the line at infinity of BC and AV be x and x', of CA and BV be y and y' and of AB and CV be z and z'. Then since $B'C'$ is parallel to VA, $C'A'$ to VB and $A'B'$ to VC we know that $B'C'$ passes through x', that $C'A'$ passes through y' and that $A'B'$ passes through z'. The fact that $A'x$, $B'y$ and $C'z$ are concurrent is immediate. For if $A'x$ meets $B'y$ in V', then $C'V'$ meets the line at infinity in the mate of z' in the involution which has (x, x') and (y, y') as pairs, and this involution is the one we are considering already. Hence $C'V'$ passes through z, and so $A'x$, $B'y$ and $C'z$ are concurrent.

ON THE INTERSECTION OF A NESTED SEQUENCE OF COMPACT SETS

B. L. McAllister, South Dakota School of Mines and Technology

1. One of the requirements of a T_1 topological space is that the intersection of any two open sets should be open. The purpose of this note is to present an example to show that the following theorem depends upon this requirement.

Theorem. *In a T_1 topological space, the elements of any nested sequence of nonempty closed sets, at least one of which is countably compact, have a nonempty intersection.*

2. To avoid possible ambiguity, terms are defined here in the sense in which they will be used. (If $\mathfrak{I}$ is any collection of sets, X will denote the underlying space, viz. $\cup\mathfrak{I}$.) We say that X (or, properly, $\mathfrak{I}$) is T_1 if for each two members p and q of X, some member of $\mathfrak{I}$ contains p but not q. A member p of X is a *limit point* of a subset S of X provided that every member of $\mathfrak{I}$ that contains p

meets $S-p$. A set is *closed* if it contains all its limit points, and *countably compact* provided that every infinite subset of it has a limit point. A sequence p_n *converges* to p if every member of $\mathfrak{I}$ that contains p contains p_n for all but a finite set of values of n.

3. Let S be the set of all polynomials with coefficients equal to 0 or 1 (including the 0-polynomial). For each k, R_k^1 is the set of all members of S such that the term x^k has coefficient 1, and R_k^0 is the set of all members of S such that the coefficient of x^k is 0. (If the degree of a polynomial is less than k, the coefficient of x^k is taken as 0.) Thus $R_k^0 \cap R_k^1 = \varnothing$. Our "pseudo topology" $\mathfrak{I}$ is the collection of all subsets of S that are unions of R_k^j's. It is at once evident that $\mathfrak{I}$ is T_1, since unequal polynomials differ in at least one coefficient.

4. Now, for $i=1, 2, \cdots$, let $M_i = \bigcap_{k=0}^{i} R_k^1$. Clearly $M_i \supset M_{i+1}$, since $\bigcap_{k=0}^{i} R_k^1 \supset \bigcap_{k=0}^{i+1} R_k^1$. Thus the sequence of M_i's is nested. Each M_i is closed, since if p is a member of $S-M_i$, then for some $k \leqq i$, $p \in R_k^0$. But $R_k^0 \in \mathfrak{I}$, and does not meet M_i (since if it did it would have to meet R_k^1). Then p is not a limit point of M_i. That is, no point outside M_i is a limit point of M_i.

On the other hand, each M_i is countably compact. For let Z be an infinite subset of M_i. Since S is countable, so is Z, say

$$Z = \{p_1, p_2, \cdots\} \quad \text{where} \quad p_k = \sum_{j=0}^{m_k} a_j^k x^j.$$

Let μ be the largest of the degrees of p_1, p_2, and p_3. We determine a polynomial $q = \sum_{j=0}^{\mu} b_j x^j$ by the following rule: For all

$$j \leqq \mu \qquad \text{if } a_j^1 = a_j^2 \quad \text{or} \quad a_j^1 = a_j^3, \quad b_j = a_j^1.$$

Otherwise, $b_j = a_j^2$ (hence also $b_j = a_j^3$). Then every member of $\mathfrak{I}$ that contains q contains either an R_k^0 or an R_k^1 that contains q and each such R_k^0 or R_k^1 contains two of the polynomials p_1, p_2, p_3, at least one of which differs from q.

Finally note that $\bigcap_{i=0}^{\infty} M_i = \varnothing$. For $0 \notin \bigcap_{i=0}^{\infty} M_i$, and for each $p \in S$, if $p \neq 0$ then p has some degree, say n. Thus

$$p \notin R_{n+1}^1, \qquad p \notin M_{n+1}, \quad \text{and} \quad p \notin \bigcap_{i=0}^{\infty} M_i.$$

REMARK. The space described above is countable and satisfies all of the requirements of a Hausdorff space except the requirement that the intersection of any two open sets be open. The author obtained this example several years ago when he was a student in a class with Professor C. E. Burgess.

The author thanks the referee for suggesting several improvements.

THE BOUNDARY VALUES OF A HOLOMORPHIC FUNCTION

P. R. CHERNOFF, Harvard University

"A function, continuous on the closed unit disc, holomorphic inside, and vanishing on an open subset of the boundary, vanishes identically. A simple proof of this well-known proposition is obtained by considering its Cauchy integral representation," [1].

Whatever the authors of [1] had in mind, it is difficult to imagine a proof simpler than the following:

Because $f(e^{i\theta})$ vanishes on an open interval, there are finitely many θ's, say $\theta_1, \cdots, \theta_n$, such that the product

$$f(ze^{i\theta_1}) \cdot f(ze^{i\theta_2}) \cdots f(ze^{i\theta_n})$$

vanishes identically on the boundary of the disc. By the maximum principle it must vanish on the entire disc. Hence one of its factors must vanish identically.

Of course, a much stronger result is known: the boundary zeros of a holomorphic function cannot have positive Lebesgue measure unless the function vanishes identically [2], but the available proofs of this fact are not nearly so elementary.

The author is an NSF graduate fellow.

CONDITION FOR A LOOP TO BE A GROUP

DONALD WATSON, RAAF Academy, Point Cook, Australia

Zassenhaus' rectangle rule (1 and 2) provides a method for deciding whether a loop is a group. I give below a generalization which improves the rule in two ways: the multiplication table of the loop need not be in any special form; the identification is made simply from the *pattern* of the table, no multiplications being necessary.

The improved rule is this. In the multiplication table of the loop choose any four places forming the vertices of a rectangle. Suppose that the entries in these places are

$$\begin{matrix} q & r \\ p & s \end{matrix}$$

If the loop is a group then all other rectangles having p, q, r, as entries at successive vertices, with p and q sharing a column, will have s as the entry at the fourth vertex. The converse is also true.

In order to prove the rule we first express it in algebraic form. The relevant extract from the table is:

	c	d
a	q	r
b	p	s

The rule then states that a necessary and sufficient condition for a loop to be a group is that for any a, b, c, d, A, B, C, D in the loop the relations

$$(1) \qquad bc = BC, \qquad ac = AC, \qquad ad = AD,$$

should imply that $bd = BD$.

The condition is necessary since if the loop is a group, multiplication is associative and therefore

$$\begin{aligned} bd &= bc(c^{-1}a^{-1})ad = bc(ac)^{-1}ad \\ &= BC(AC)^{-1}AD = BC(C^{-1}A^{-1})AD = BD. \end{aligned}$$

To prove the sufficiency of the condition we must show that the condition implies that the loop is associative, that is,

$$x(yz) = (xy)z,$$

where x, y, z are any members of the loop. To do this we choose

$$a, b, c, d, A, B, C, D \qquad \text{as } i, x, yi, yz, iy, xy, i, z,$$

where i is the identity element of the loop. These substitutions will satisfy the relations (1) and it follows that

$$x(yz) = (xy)z.$$

Editor's Note. Professor Parker, author of the note [2] referred to in the bibliography of the preceding paper, has pointed out that the rule he stated in his paper provides a necessary, but not a sufficient, condition for a loop to be a group. This point was not made clear in Professor Parker's paper.

GRAPH EXTENSION PRESERVING CHROMATIC NUMBER

T. K. SHENG, University of Malaya, Kuala Lumpur

Let G be any finite graph without isolated vertices. In this note we give a method for extending G to a larger finite regular graph H, with the same chromatic number as G. The graph H is interesting insofar as it is entirely composed of copies of G, and the method of forming H can be likened to the way in which

chemical crystals grow. Our result was conjectured by H. H. Teh, who gave (unpublished lecture notes) an infinite extension of G.

We first illustrate the method with an example. Suppose G is given by Fig. 1, and colored with 2 colors α, β. Then we take 4 copies of G as shown in Fig. 2, and combine those vertices contained in dotted lines to obtain H in Fig. 3.

FIG. 1. Graph G.

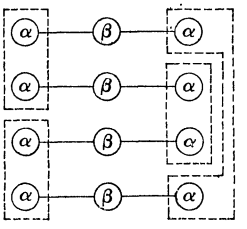

FIG. 2

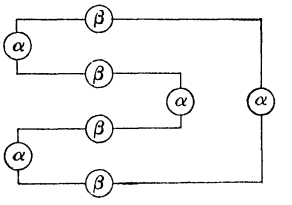

FIG. 3. Graph H.

Moreover, H is colored with α and β. It can in fact be seen that H has the properties listed in our general theorem:

THEOREM. *Let G be any finite graph with vertices $p_1, p_2, \cdots, p_n$ of nonzero local degrees $\rho_1, \rho_2, \cdots, \rho_n$. Then G can be extended to a finite graph H with the following properties*:

(a) *H is entirely composed of copies of G and any two of the copies have at most one vertex in common in H.*

(b) *H is connected (disconnected) if G is connected (disconnected).*

(c) *The chromatic number of H is the chromatic number of G.*

(d) *H is regular of degree N = least common multiple $(\rho_1, \rho_2, \cdots, \rho_n)$.*

(e) *H contains at least s subgraphs which are copies of G, where*

$$s = N^n/\rho_1\rho_2 \cdots \rho_n. \tag{1}$$

(f) *The number of vertices in H is $v = N^{n-1}(\rho_1+\rho_2+\cdots+\rho_n)/(\rho_1\rho_2\cdots\rho_n)$.*

Proof. We take s identical copies of G, where s is defined by (1), and index them as $G(x_1, x_2, \cdots, x_n)$, where for

$$i = 1, 2, \cdots, n, \qquad \text{we have } x_i = 1, 2, \cdots, N/\rho_i. \tag{2}$$

Then we combine vertices out of these copies of G to form H as follows. For given fixed i and fixed $x_1, x_2, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n$ satisfying (2), we combine as a single vertex of H, the ith vertices p_i of N/ρ_i of the copies of G, namely the copies

$$G(x_1, x_2, \cdots, x_{i-1}, x_i, x_{i+1}, \cdots, x_n); \qquad x_i = 1, 2, \cdots, N/\rho_i.$$

The resulting vertex of H has local degree $\rho_i(N/\rho_i) = N$. We do this combining process for all choices of i and $x_1, x_2, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n$ satisfying (2).

Consider now the resulting graph H. By construction H is entirely composed

of copies of G. Let G_1, G_2 be any two copies, say

$$G_1 = G(x_1', x_2', \cdots, x_n') \quad \text{and} \quad G_2 = G(x_1'', x_2'', \cdots, x_n''). \tag{3}$$

Suppose G_1 and G_2 have their ith vertices p_i combined in H. Then $x_j' = x_j''$ for $1 \leqq j \leqq n$; $j \neq i$. Therefore if G_1 and G_2 are distinct they have at most one vertex in common, and so (a) holds.

Next we prove (b). If G is a disconnected graph, then since in forming vertices of H, we combined only corresponding vertices p_i, p_i of the copies of G, we must have H disconnected. Suppose on the other hand that G is connected, and let G_1, G_2 be the two copies (3) of G. Then in the sequence of copies

$$G(x_1', x_2', \cdots, x_n'), \cdots, G(x_1'', \cdots, x_{i-1}'', x_i', \cdots, x_n') \cdots,$$
$$G(x_1'', \cdots, x_i'', x_{i+1}', \cdots, x_n'), \cdots, G(x_1'', x_2'', \cdots, x_n''),$$

any two consecutive copies have one point in common. Hence H is connected.

The result (c) follows from the fact that only corresponding vertices of the copies of G are combined. We have already mentioned that each vertex of H has local degree N, and we start the construction with s copies of G, so (d) and (e) hold.

Finally to prove (f), we note that s copies of G contain

$$\tfrac{1}{2}(\rho_1 + \rho_2 + \cdots + \rho_n)s = \tfrac{1}{2}N^n(\rho_1 + \rho_2 + \cdots + \rho_n)/(\rho_1\rho_2 \cdots \rho_n)$$

edges and H contains $\frac{1}{2}Nv$ edges. Hence it follows that

$$\tfrac{1}{2}Nv = \tfrac{1}{2}N^n(\rho_1 + \rho_2 + \cdots + \rho_n)/(\rho_1\rho_2 \cdots \rho_n).$$

This proves (f).

The author would like to thank Prof. E. S. Barnes, Prof. D. E. Daykin and Prof. H. H. Teh for their encouragement and assistance in writing this paper.

ON A WELL-KNOWN IMPROPER INTEGRAL

HIROSHI HARUKI, Osaka University (Now at University of Waterloo, Canada)

We consider the well-known improper integral (a real)

$$f(a) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp(-x^2) \cos axdx, \tag{1}$$

which is an extension of the probability integral $(1/\sqrt{\pi})\int_{-\infty}^{+\infty} \exp(-x^2)dx (=1)$.

The usual methods of evaluating this integral ($f(a) = \exp(-a^2/4)$) are the following three:

(A) The method of using integration by parts and deducing the differential equation $f'(a) = -\frac{1}{2}af(a)$ with the initial condition $f(0) = 1$. (See [2] p. 433.)

(B) The method of using power series and termwise integration. (See [2] p. 460.)

(C) The method of using analytic function theory. (See [3] p. 87.)

Now we shall prove that $f(a)=\exp(-a^2/4)$ from the standpoint of functional equation theory by using the following lemma (see [1] pp. 74, 96):

LEMMA. *If a real-valued function $f(x)$ is continuous in $-\infty<x<+\infty$, and satisfies the functional equation $f(s)f(t)=f(\sqrt{s^2+t^2})$ for real values of s and t, then*

$$f(x) = 0 \quad \text{or} \quad f(x) = \exp(\alpha x^2),$$

where α is an arbitrary real constant.

Proof of $f(a)=\exp(-a^2/4)$: By (1) we have

$$f(s)f(t) = \frac{1}{\pi}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} \exp(-x^2-y^2)\cos sx\cos ty\,dxdy, \tag{2}$$

where s, t are arbitrary real numbers. By (2) we have

$$\begin{aligned} f(s)f(t) = \frac{1}{2\pi}\Bigg(&\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} \exp(-x^2-y^2)\cos(sx+ty)\,dxdy \\ &+\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} \exp(-x^2-y^2)\cos(sx-ty)\,dxdy\Bigg) = \frac{1}{2\pi}(I_1+I_2). \end{aligned} \tag{3}$$

Putting in I_1 (when $s^2+t^2>0$)

$$x = \frac{s}{\sqrt{s^2+t^2}}u - \frac{t}{\sqrt{s^2+t^2}}v, \qquad y = \frac{t}{\sqrt{s^2+t^2}}u + \frac{s}{\sqrt{s^2+t^2}}v,$$

we have (Jacobian $=1$, $x^2+y^2=u^2+v^2$)

$$\begin{aligned} I_1 &= \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} \exp(-u^2-v^2)\cos(\sqrt{s^2+t^2}\,u)\,dudv \\ &= \int_{-\infty}^{+\infty}\exp(-v^2)dv\int_{-\infty}^{+\infty}\exp(-u^2)\cos(\sqrt{s^2+t^2}\,u)\,du \\ &= \sqrt{\pi}\sqrt{\pi}f(\sqrt{s^2+t^2}) = \pi f(\sqrt{s^2+t^2}). \end{aligned} \tag{4}$$

By the above result we have

$$I_2 = \pi f(\sqrt{s^2+(-t)^2}) = \pi f(\sqrt{s^2+t^2}). \tag{5}$$

By (3), (4), (5) we have

$$f(s)f(t) = f(\sqrt{s^2+t^2}). \tag{6}$$

By the continuity of $f(a)$, (6) and $f(0)=1$, the above lemma gives

$$f(a) = \exp(\alpha a^2), \tag{7}$$

where α is a real constant. By (1) we have

$$f''(0) = -(1/\sqrt{\pi})\int_{-\infty}^{+\infty} x^2 \exp(-x^2)dx = -\tfrac{1}{2}. \tag{8}$$

By (7), (8) we have $\alpha = -\frac{1}{4}$. Hence, by (7) we have $f(a) = \exp(-a^2/4)$.

ON THE MATRIX EQUATION $AB=I$

PAUL HILL, University of Houston

In a course in linear algebra, and elsewhere, it is a great computational convenience to know that if A and B are n-square matrices such that $AB=I$, where I is the identity matrix of order n, then necessarily $BA=I$ and B is the inverse of A. A standard proof of this result is the identification of a matrix with its corresponding linear transformation and the proof that a linear transformation of a finite dimensional vector space is onto if and only if it is one-to-one. There is, however, an elementary direct proof of an even stronger result which is almost an immediate consequence of an interesting theorem about matrices that is not so well known, although its proof is quite simple.

Suppose that R is a ring and that n is a positive integer. Let R_n denote the ring of all n-square matrices over R. We emphasize that R need not be commutative.

THEOREM. *If R satisfies the ascending chain condition for right ideals, then so does R_n.*

Proof. Denote by $f_{i,j}$ the function from R_n to R that sends a matrix onto its (i, j)-component. Observe that if S is a nonempty subset of R_n which is closed with respect to addition, subtraction, and scalar multiplication on the right, then $f_{i,j}(S)$ is a right ideal of R.

Assume that $\{E_k\}$ is a sequence of right ideals of R_n such that E_k is properly contained in E_{k+1} for each positive integer k. For each positive integer t not exceeding n^2 let $E_{k,t}$ denote the subset of E_k consisting of those matrices in E_k that have zero in each of the first t components—for definiteness, count the components by rows. Now suppose that t is less than n^2 and that we have already shown that $E_{k,t}$ is properly contained in $E_{k+1,t}$ for all but a finite number of k. We wish to show that the latter result must also hold for $t+1$. Since $f_{i,j}(E_{k,t})$ is a right ideal of R and since R satisfies the ascending chain condition, we know that $f_{i,j}(E_{k,t}) = f_{i,j}(E_{k+1,t})$ for all but a finite number of k. If this equality holds, however, and if $E_{k,t}$ is proper in $E_{k+1,t}$, then $E_{k,t+1}$ is proper in $E_{k+1,t+1}$; for if A is in $E_{k+1,t}$ but not in $E_{k,t}$, then there exists B in $E_{k,t}$ having the same $(t+1)$-

component as A and $B-A$ is in $E_{k+1,t+1}$ but not in $E_{k,t+1}$. We are led to the conclusion that the set consisting of only the zero matrix in R_n is a proper subset of itself. Thus our assumption must be denied, and R_n satisfies the ascending chain condition for right ideals.

The next theorem is a weak version of Theorem 4 in [1].

THEOREM. *If R is a ring with unit which satisfies the ascending chain condition for right ideals, then the equation $ab=1$ in R implies that $ba=1$.*

Proof. Define a mapping π from R into itself by: $x\to ax$. Since $\pi(bx)=x$ for each x in R, π is onto. Let $K_n=\{x\in R\mid \pi^n(x)=0\}$ denote the kernel of π^n for each positive integer n. Since K_n is a right ideal of R, there must be a positive integer n such that $K_n=K_{n+1}$. For any such n, we see that $\pi(\pi^n(x))=0$ implies that $\pi^n(x)=0$. Since π^n is onto and since π preserves addition, π must be one-to-one. Since $\pi(1)=\pi(ba)$, $ba=1$ and the theorem is proved.

COROLLARY. *If R is a field or division ring and if A and B are n-square matrices over R such that $AB=I$, then $BA=I$.*

Proof. R has only the two trivial right ideals.

Both of the above theorems can be proved, in much the same way, for the descending chain condition and also for left ideals, so we actually have

THEOREM. *If R is a ring with unit which satisfies the ascending (descending) chain condition for right (left) ideals and if A and B are n-square matrices over R such that $AB=I$, then $BA=I$.*

TITCHMARSH'S THEOREM FOR ANALYTIC FUNCTIONS

M. R. VIRGA, University of Michigan (Undergraduate student)

The convolution of two functions f and g written $f*g$ is a function defined on $[0,\ \infty)$ by $f*g(t)=\int_0^t f(u)g(t-u)du$. An important property of convolutions, which was first proved (in [1]) by E. Titchmarsh, is: If f and g are continuous on $[0,\ \infty)$ and if $f*g=0$, then $f=0$ or $g=0$.

Jan Mikusinski makes use of this property of convolution products to construct convolution quotients, the theory of which provides a rigorous basis for Heaviside's operational calculus. He presents a different proof of Titchmarsh's theorem in [2].

An elementary proof can be given for the following special case of Titchmarsh's theorem:

THEOREM. *If f and g are analytic functions on an interval I which includes the origin and if $f*g=0$ on I, then either $f=0$ or $g=0$ on I.*

The proof of this theorem will make use of the following properties of convolutions. First, by making the change of variable $v=t-u$, we obtain

$$f * g = \int_0^t f(u)g(t-u)du = \int_0^t f(t-v)g(v)dv = g * f. \tag{1}$$

Next, using Leibnitz's rule for derivatives of integrals depending on a parameter, we obtain

$$\begin{aligned}(f * g)' &= \frac{d}{dt}\left(\int_0^t f(u)g(t-u)du\right) \\ &= f(t)g(t-t) + \int_0^t f(u)\frac{\partial}{\partial t}g(t-u)du \\ &= f(t)g(0) + f * g'.\end{aligned} \tag{2}$$

Since $f * g = g * f$, we also have

$$(f * g)' = f(0)g(t) + f' * g. \tag{2'}$$

Finally if $h(t) = f * g(t)$, then

$$h(0) = \int_0^0 f(u)g(-u)du = 0. \tag{3}$$

LEMMA 1. *If $f * g = 0$ and if $f(0) \neq 0$, then $g(0) = 0$, $f * g' = 0$, and consequently $g^{(n)}(0) = 0$ for $n = 0, 1, 2, \cdots$.*

Proof. From (2) and (2') we have

$$(f * g)' = f(0)g(t) + f' * g \tag{4}$$

$$(f * g)' = g(0)f(t) + f * g'. \tag{5}$$

Both of these expressions are identically equal to zero since $(f * g)' = 0$. Thus, by (4), $g(t) = (-1/f(0))f' * g$. Hence, by (3), $g(0) = 0$, and consequently $f * g' = 0$ from (5). By successively substituting $g^{(k)}$ for $g^{(k-1)}$ in this argument, we obtain $g^{(k)}(0) = 0$ and $f * g^{(k+1)} = 0$, for values of $k = 1, 2, \cdots$. Thus $g^{(n)}(0) = 0$ for $n = 0, 1, 2, \cdots$.

LEMMA 2. *If $f * g = 0$ and $f(0) = 0$, then $f' * g = 0$ and either $f'(0) = 0$ or $g^{(n)}(0) = 0$ for $n = 0, 1 \cdots$.*

Proof. From (2') we have $(f * g)' = f(0)g(t) + f' * g = f' * g$, since $f(0) = 0$. Since $(f * g)' = 0$, it follows that $f' * g = 0$. If $f'(0) \neq 0$ we can then substitute f' for f in Lemma 1 and obtain the result that $g^{(n)}(0) = 0$ for $n = 0, 1, \cdots$.

Proof of Theorem. We shall show that under our hypotheses $f^{(n)}(0) = 0$ or $g^{(n)}(0) = 0$ for all n. This will complete the proof. If $f * g = 0$ and $f(0) \neq 0$, then it follows from Lemma 1 that $g^{(n)}(0) = 0$ for all n. If on the other hand $f(0) = 0$, and $g^{(n)}(0) \neq 0$ for some n, then $f'(0) = 0$ and by successively substituting $f^{(k)}$

for $f^{(k-1)}$ in Lemma 2, we obtain the result that $f^{(k+1)}(0)=0$ and that $f^{(k+1)} * g=0$, for values of $k=1, 2, \cdots$. Thus in this case $f^{(n)}(0)=0$ for all n.

Acknowledgement: I wish to acknowledge my sense of gratitude to Professor J. A. Smoller for his guidance during the preparation of this paper.

MATRICES WHICH TAKE A GIVEN VECTOR INTO A GIVEN VECTOR

M. MACHOVER, St. John's University

A slight variation of the usual problem for a system of linear equations is to solve for the coefficient matrix when the solution vector is known. More abstractly, if V and W are n- and m-dimensional vector spaces over the same field, and $x \in V$ and $y \in W$, find all linear transformations L such that $Lx=y$. In this note we answer the question completely and in fact give a procedure for writing down the solution from inspection.

Since we are dealing with the finite-dimensional case we may assume x and y are given column vectors and L is an $m \times n$ matrix. When $x=0$ a solution clearly exists if and only if $y=0$, and is in fact any $m \times n$ matrix. The case for $x \neq 0$ is governed by the following:

THEOREM. *Let $x \neq 0$ and y be column vectors of n and m components, respectively (with elements from the same field). Suppose the p-th component of x is not zero. The set of all matrices L such that $Lx=y$ is nonempty, and is given by*

$$L = L^0 + \sum_{r=1}^{n}{}' \sum_{q=1}^{m} \alpha_{qr} L^{qr} \tag{1}$$

(the prime denotes that r does not take on the value p), where the α_{qr} are arbitrary constants (scalars of the field), and

$$\begin{aligned} L^0_{ij} &= (y_i \delta_{jp})/x_p, && i = 1, 2, \cdots, m; \quad j = 1, 2, \cdots, n, \\ & && (\delta_{ij} \text{ is the "Kronecker delta"}) \\ L^{qr}_{ij} &= x_r \delta_{iq} \delta_{jp} - x_p \delta_{iq} \delta_{jr}, && i = 1, 2, \cdots, m; \quad j = 1, 2, \cdots, n. \end{aligned} \tag{2}$$

Proof. The equations $Lx=y$ or

$$\begin{aligned} L_{11}x_1 + L_{12}x_2 + \cdots + L_{1n}x_n &= y_1 \\ L_{21}x_1 + L_{22}x_2 + \cdots + L_{2n}x_n &= y_2 \\ \cdots\cdots\cdots\cdots\cdots\cdots & \\ L_{m1}x_1 + L_{m2}x_2 + \cdots + L_{mn}x_n &= y_m \end{aligned} \tag{3}$$

may be rewritten as

$$(4)\qquad \begin{bmatrix} x_1 & x_2 & \cdots & x_n & 0 & 0 & \cdots & 0 & 00 & \cdots & 0 & \cdots & \cdots \\ 0 & 0 & \cdots & 0 & x_1 & x_2 & \cdots & x_n & 00 & \cdots & 0 & \cdots & \cdots \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdots & \cdots \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdots & \cdots \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 00 & \cdots & 0 & x_1x_2 & \cdots x_n \end{bmatrix} \begin{bmatrix} L_{11} \\ L_{12} \\ \cdot \\ \cdot \\ L_{1n} \\ L_{21} \\ L_{22} \\ \cdot \\ \cdot \\ L_{2n} \\ \cdot \\ \cdot \\ L_{mn} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \cdot \\ \cdot \\ y_m \end{bmatrix}$$

Denoting this $m \times mn$ coefficient matrix by X, we see that its rank is m since $x_p \neq 0$. Since the rank of the augmented matrix is also m there is a solution L to this system. Also the associated homogeneous system has $nm-m=(n-1)m$ linearly independent solutions. Thus the general solution is the sum of a particular solution plus an arbitrary linear combination of $(n-1)m$ linearly independent solutions of the homogeneous system. One may readily check that L^0 and the L^{qr} as defined by (2) are these required solutions. (They may be obtained by applying Gaussian elimination to (4).)

We observe that L^0 and the L^{qr} may be immediately written down from an inspection of (3). The pth column of L^0 is y/x_p, all the other entries are zero. The qth row of L^{qr} contains x_r in the pth column and $-x_p$ in the rth column. All its other rows are zero. Thus the set of all matrices A satisfying

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \end{bmatrix} \begin{bmatrix} 1 \\ -1 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 \\ 5 \end{bmatrix}$$

is immediately seen to be (we will work with $p_1=1$)

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 5 & 0 & 0 \end{bmatrix} + \alpha_{12} \begin{bmatrix} -1 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix} + \alpha_{22} \begin{bmatrix} 0 & 0 & 0 \\ -1 & -1 & 0 \end{bmatrix}$$
$$+ \alpha_{13} \begin{bmatrix} 2 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix} + \alpha_{23} \begin{bmatrix} 0 & 0 & 0 \\ 2 & 0 & -1 \end{bmatrix}$$

Although the question is easily answered in the finite-dimensional case it offers new difficulties when we proceed to infinite dimensions, especially when we restrict the class of permissible transformations. A typical question might be to find all kernels of the integral equation $\int_a^b k(s,t)f(t)dt = g(s)$ once f and g are specified.

PROOF OF THE FUNDAMENTAL THEOREM OF ALGEBRA

S. WOLFENSTEIN, Université de Paris

The so-called Fundamental Theorem of Algebra states that every nonconstant polynomial with complex coefficients has at least one complex zero; or alternatively, that if p is any nonconstant polynomial function of a complex variable, then the range of p contains every complex number.

The purpose of the present note is to sketch a proof simpler than appears currently available and in any case employing no mathematical tools more sophisticated than are already required for elementary calculus. The proof is based upon the convergence of an iterative procedure, a notion which should be familiar to beginning students (Newton's method, Picard's method). Prerequisites are as follows:

(A) A nonzero polynomial has only a finite number of zeros.

(B) If f: $R^m \to R^n$ is a continuous function such that $|f(x)|$ goes to infinity with $|x|$ (in particular if f is a nonconstant polynomial function of a complex variable), then the range of f is closed. (This follows at once from Weierstrass's Theorem that every bounded sequence has a convergent subsequence.)

(C) For $n>1$, the complement of a finite subset of R^n is connected. In addition only the most elementary properties of complex numbers are needed.

LEMMA. *Let p be a nonconstant polynomial function of a complex variable, S the range of p and $T=\{p(z): p'(z)=0\}$. Then $S-T$ is open.*

Proof. We first show that if $|c|$ is sufficiently small the equation

$$w + \sum_{m=2}^{n} b_m w^m = c \tag{1}$$

has a root that can be approximated by iteration. Let $w_0=0$,

$$w_{k+1} = c - \sum_{m=2}^{n} b_m w_k^m,$$

clearly if the sequence w_k converges at all it converges to a root of (1). Suppose now that $|c|$ is small; specifically, let α be any positive number less than 1, $\rho=\min(\alpha/[\sum_{m=2}^{n} m|b_m|], 1)$ and $|c|<\rho-\sum_{m=2}^{n}|b_m|\rho^m$ (this is a positive number). A straightforward inductive calculation shows that, for all k, $|w_k|\leqq\rho$. Further, for $k>0$,

$$\begin{aligned} |w_{k+1}-w_k| &= |w_k-w_{k-1}|\left|\sum_{m=2}^{n} b_m \sum_{s=1}^{m} w_k^{m-s} w_{k-1}^{s-1}\right| \\ &\leqq |w_k-w_{k-1}| \sum_{m=2}^{n} m|b_m|\rho^{m-1}, \quad \text{by the foregoing,} \\ &\leqq \alpha|w_k-w_{k-1}|, \end{aligned}$$

so that, for c as stated, w_k does converge to a root of (1).

Now let p be any nonconstant polynomial, z_0 any complex number such that $p'(z_0)\neq 0$. With the substitutions $z=z_0+w$, $a=p(z_0)+p'(z_0)c$, the result just obtained shows that the equation $p(z)=a$ has a root for all values of a close enough to $p(z_0)$. In other words, if z_0 is not a zero of p', $p(z_0)$ is an interior point of S. This proves the Lemma.

THEOREM. *With the notation of the lemma, S is the set of all complex numbers.*

Proof. The complement of S is open (B), and $S-T$ is open by the lemma. But as T is finite (A) its complement cannot consist of two disjoint nonempty open sets (C). Hence the complement of S must be empty.

AN EASY PROOF OF THE FUNDAMENTAL THEOREM OF ALGEBRA

CHARLES FEFFERMAN, University of Maryland

THEOREM. *Let $P(z)=a_0+a_1z+\cdots+a_nz^n$ be a complex polynomial. Then P has a zero.*

Proof. We shall show first that $|P(z)|$ attains a minimum as z varies over the entire complex plane, and next that if $|P(z_0)|$ is the minimum of $|P(z)|$, then $P(z_0)=0$.

Since $|P(z)|=|z|^n|a_n+a_{n-1}/z+\cdots+a_0/z^n|$ $(z\neq 0)$, we can find an $M>0$ so large that

$$|P(z)| \geqq |a_0| \qquad (|z|>M). \tag{1}$$

Now, the continuous function $|P(z)|$ attains a minimum as z varies over the compact disc $\{|z|\,|z|\leqq M\}$. Suppose, then, that

$$|P(z_0)| \leqq |P(z)| \qquad (|z|\leqq M). \tag{2}$$

In particular, $|P(z_0)|\leqq P(0)=|a_0|$ so that, by (1), $|P(z_0)|\leqq|P(z)|$ $(|z|>M)$. Comparing with (2), we have

$$|P(z_0)| \leqq |P(z)| \qquad \text{(all complex } z\text{)}. \tag{3}$$

Since $P(z)=P((z-z_0)+z_0)$, we can write $P(z)$ as a sum of powers of $z-z_0$, so that for some complex polynomial Q,

$$P(z) = Q(z-z_0). \tag{4}$$

By (3) and (4),

$$|Q(0)| \leqq |Q(z)| \qquad \text{(all complex } z\text{)}. \tag{5}$$

We shall show that $Q(0)=0$. This will establish the theorem since, by (4), $P(z_0)=Q(0)$.

Let j be the smallest nonzero exponent for which z^j has a nonzero coefficient in Q. Then we can write $Q(z)=c_0+c_jz^j+\cdots+c_nz^n$ $(c_j\neq 0)$. Factoring

z^{j+1} from the higher terms of this expression, we have

$$Q(z) = c_0 + c_j z^j + z^{j+1}R(z), \tag{6}$$

where $c_j \neq 0$ and R is a complex polynomial.

If we set $-c_0/c_j = re^{i\theta}$, then the constant $z_1 = r^{1/j}e^{i\theta/j}$ satisfies

$$c_j z_1^j = -c_0. \tag{7}$$

Let $\epsilon > 0$ be arbitrary. Then, by (6),

$$Q(\epsilon z_1) = c_0 + c_j \epsilon^j z_1^j + \epsilon^{j+1} z_1^{j+1} R(\epsilon z_1). \tag{8}$$

Since polynomials are bounded on finite discs, we can find an $N > 0$ so large that, for $0 < \epsilon < 1$, $|R(\epsilon z_1)| \leqq N$. Then, by (7) and (8) we have, for $0 < \epsilon < 1$,

$$\begin{aligned} |Q(\epsilon z_1)| &\leqq |c_0 + c_j \epsilon^j z_1^j| + \epsilon^{j+1} |z_1|^{j+1} |R(\epsilon z_1)| \\ &\leqq |c_0 + \epsilon^j (c_j z_1^j)| + \epsilon^{j+1}(|z_1|^{j+1} N) \\ &= |c_0 + \epsilon^j (-c_0)| + \epsilon^{j+1}(|z_1|^{j+1} N) \\ &= (1 - \epsilon^j)|c_0| + \epsilon^{j+1}(|z_1|^{j+1} N) \\ &= |c_0| - \epsilon^j |c_0| + \epsilon^{j+1}(|z_1|^{j+1} N). \end{aligned} \tag{9}$$

If $|c_0| \neq 0$, then we can take ϵ so small that $\epsilon^{j+1}(|z_1|^{j+1} N) < \epsilon^j |c_0|$. In that case, by (9)

$$|Q(\epsilon z_1)| \leqq |c_0| - \epsilon^j |c_0| + \epsilon^{j+1}(|z_1|^{j+1} N) < |c_0| = |Q(0)|,$$

contradicting (5). So $|c_0| = 0$, and therefore $Q(0) = c_0 = 0$.

MATHEMATICAL EDUCATION NOTES

EDITED BY JOHN R. MAYOR, AAAS and University of Maryland
COLLABORATING EDITOR: JOHN A. BROWN, University of Delaware

Material for this department should be sent to John R. Mayor, 1515 Massachusetts Avenue, N.W., Washington, D.C. 20005.

SEARCHING FOR MATHEMATICAL TALENT IN WISCONSIN, III.

D. W. CROWE, University of Wisconsin

The Wisconsin High School Mathematical Talent Search operated for its third year in 1965–66, with continuing financial support from the National Science Foundation. Reports for preceding years are given in references [1], [2].

The following five problem sets were used. In parenthesis after each problem is the number of students who submitted essentially correct solutions.

Problem Set 1—Sept. 20, 1965

1. Prove that $\sqrt[3]{15}$ is not a rational number. (16)

2. (a) A *cute* girl only eats cake cut in pieces the shape of *acute* triangles. Show how to cut a rectangular cake (of unequal sides) to serve cute girls, with no pieces left over. (The pieces do not all have to be the same size, but must all be acute triangles.)

(b) Show how to do the same for a square cake. (49)

The symbol "y^{z^w}" means "y raised to the power z^w." The symbol "$x^{y^{z^w}}$" means "x raised to the power y^{z^w}."

3. Prove that $2^{2^{2^2}}-2^{2^2}$ divides $n^{2^{2^2}}-n^{2^2}$ for all integers n. (42)

4. (a) Three wrestlers find themselves in the (30 foot square) ring at the same time. Each, being deathly afraid of the other two, wants to keep as far from them as possible. Prove: They can stand so that no two of them are closer than $60\sqrt{2-\sqrt{3}}$ feet from each other.

(b) Prove that the number $60\sqrt{2-\sqrt{3}}$ cannot be replaced by a larger number in the last statement. (19)

Food for thought: What if there are more wrestlers?

5. A student "solved" the quadratic equation $x^2+x-2=0$ as follows:

$$\begin{aligned} & x^2 + x - 2 = 0, \\ \therefore\ & -x^2 - x + 6 = 4, \\ \therefore\ & (x+3)(2-x) = 4, \\ \therefore\ & \text{Either } x+3 = 4, \quad \text{hence } x = 1 \\ & \text{or } 2 - x = 4, \quad \text{hence } x = -2. \end{aligned}$$

These are, in fact, the roots of the original equation.

Can you find a quadratic equation with integral roots which cannot be "solved" this way?

More exactly: Can you find a quadratic equation, $x^2+bx+c=0$, having integral roots, which cannot be rewritten as

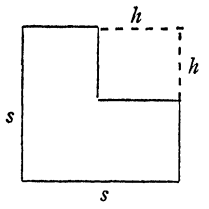
$$(x-d)(-e-x) = f, \qquad (f \neq 0),$$

where $d+f$ and $-(e+f)$ are the roots of the original equation? (20)

Problem Set 2—October 29, 1965

1. It is known that no root of $x^3=15$ is rational (Problem Set 1, problem #1).

(a) Prove that if $a+b\sqrt{c}$ (a, b, c rational numbers, $\sqrt{c}$ not rational) satisfies the equation $x^3=15$ then $a-b\sqrt{c}$ satisfies the same equation.



(b) Deduce that $\sqrt[3]{15}$ is not of the form $a+b\sqrt{c}$ if a, b, c are rational numbers. (14)

2. A cake is in the shape of an obtuse triangle. Show that it can be cut to serve cute girls, with no pieces left over. (That is, show how to dissect an obtuse triangle into a finite number of acute triangles.) (20)

3. Find all solutions, in nonnegative integers m, n, of the equation

$$3 \cdot 2^m + 1 = n^2. \qquad (35)$$

4. A square house of side h has been built at the corner of a square lot of side $s>h$, (see figure).

What is the largest square garage which can be built on the remainder of the lot? Prove your result. (1)

5. (a) Let a, b, c, d be integers for which $ad \neq bc$. Show that it is always possible to write the fraction $1/[(ax+b)(cx+d)]$ in the form

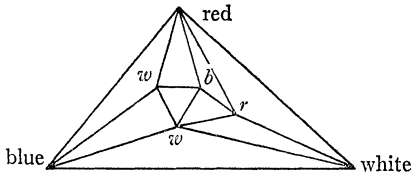
$$\frac{r}{ax+b}+\frac{s}{cx+d},$$

where r and s are rational numbers.

(b) Find the sum

$$\frac{1}{1\cdot 4}+\frac{1}{4\cdot 7}+\frac{1}{7\cdot 10}+\cdots+\frac{1}{2998\cdot 3001}. \qquad (7)$$

Problem Set 3—December 6, 1965



1. How many right triangles are there whose legs have whole number lengths and whose hypotenuse has the length $\sqrt{2}\cdot 2^n$ (where n is a given positive integer)? (22)

2. Three parallel lines (not necessarily equally spaced) are drawn in the plane. Show how to construct (with ruler and compass) an equilateral triangle with one vertex on each line. (46)

3. Use each of the digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 exactly once to form two five digit numbers having the largest possible product. (Proof?) (63)

4. What is the least number of soldiers which can march in exactly 64 different rectangular formations? (For example, six soldiers can march in exactly 4 different formations: 6×1, 3×2, 2×3, 1×6.) (44)

5. At the three corners of a large triangular field are red, white, and blue posts, respectively. The field is subdivided into smaller triangular fields, with fenceposts at each corner. (However, no fencepost is added along an already existing fence.) Each of these fenceposts is then painted one or another of the three colors red, white and blue. Prove that no matter how this is done there is always at least one small field having no two corner posts the same color. (15)

Problem Set 4—February 1, 1966

1. Six cute girls, each wearing a new hat, met at a beauty salon. After having their hair done, each girl borrowed another girl's hat and each left the salon with a hat different from the one she arrived in. That hat borrowed by Ann belonged to the borrower of Betty's hat. The owner of the hat borrowed by Cathy borrowed the hat belonging to the borrower of Debby's hat. If the borrower of Ellen's hat was not the owner of that borrowed by Flora, who borrowed Ann's hat? Whose hat did Ann borrow? How do you know? (57)

2. A square cake has frosting on its top and all four sides. Show how to cut it to serve nine people so that each of them gets exactly the same amount of cake and exactly the same amount of frosting. (The people you serve don't have to be cute girls!) (52)

3. Prove or disprove: There are two numbers x, y such that

$$x + y = 1, \quad x^2 + y^2 = 2, \quad \text{and} \quad x^3 + y^3 = 3.$$

Let v be the number of vertices of a polyhedron, e the number of edges and f the number of faces. Then Euler's theorem is: *If a polyhedron is convex, then* $v-e+f=2$. (54)

4. (a) By counting the edges of each face of a convex polyhedron, and the edges at each vertex, show that $3f \leqq 2e$ and $3v \leqq 2e$.

(b) Prove or disprove: It is possible to cut a potato into a (convex) polyhedron having exactly seven edges. (22)

5. Prove: If $1+4^d+4^{2d}+\cdots+4^{(n-1)d}$ is a perfect square then n must be odd. (6)

Problem Set 5—March 7, 1966

1. A boy has k girl friends. For each two of these girls he makes a decision as to which is cuter. (However, the fact that he says Helen is cuter than Penelope and Penelope cuter than Marilyn does not mean that he says Helen is cuter than Marilyn.)

(a) Is it then always possible to list these k girls in some order, say $g_1, g_2, \cdots, g_k$ so that g_1 is cuter than g_2, g_2 is cuter than g_3, $\cdots$, g_{k-1} is cuter than g_k? (Proof?)

(b) Suppose, in a given situation, it is possible to arrange the girls as in (a), and suppose also that g_1 is cuter than g_k. Is this arrangement necessarily the only one satisfying the original conditions? (Proof?) (11)

2. If x and y are fixed real numbers such that $x+y=1$ and $x^4+y^4=c$, find x^2+y^2 and x^3+y^3 (in terms of c). (10)

The *Fibonacci numbers* are 1,2,3,5,8,13, $\cdots$, where each one (after the second) is obtained by adding together the previous two numbers in the sequence.

3. Prove that every positive integer can be written as the sum of *distinct* Fibonacci numbers. (11)

4. 100 points are distributed in space so that no three are collinear. Prove that it is possible to draw 2500 segments joining them, so that no triangle (having 3 of the 100 points as vertices) is formed. (18)

5. Find all positive integers n which have the property that the product of their distinct (positive) divisors is n^2. (For example, 6 is such a number, since $1\cdot2\cdot3\cdot6=6^2$.) (19)

RESEARCH WORKERS IN MATHEMATICS EDUCATION

OTTO BASSLER, George Peabody College for Teachers

One of the critical needs in mathematics education is the need for trained researchers to investigate problems in how students learn mathematics, what the mathematics curriculum should include at various levels of instruction, and what methodological techniques are best suited for presentation of the specific content to be taught. This need was underscored by the Conference on Needed Research in Mathematical Education in their Summary Report. This conference concludes that there is a particular need for people who know both good mathematics and psychology.

The Institute on School Learning and Individual Differences at George Peabody College for Teachers has designed and instituted a doctoral program to train prospective research workers in several academic areas. The academic areas that are represented in the program at the present time are elementary education, English and mathematics. Administration of the program is a joint endeavor involving the academic departments and the department of psychology.

Mathematics students accepted in this program will pursue graduate study in mathematics and psychology. The graduate mathematics courses are designed to provide a firm foundation in algebra, geometry and analysis. A further emphasis in the mathematics curriculum will be placed upon the teaching of mathematics and research in mathematics education. The coursework in psychology emphasizes learning theory and research skills such as experimental design, statistical inference and problems in testing and measurement. The major goal of the coursework is to provide a firm foundation in mathematics and to prepare the student to become a researcher in mathematics education.

During the students' entire tenure in this program, they will actively participate on faculty-student research teams which investigate learning problems in mathematics. In this way the students will gain practical experience in planning, conducting, and evaluating meaningful research projects in their area of interest in conjunction with their coursework.

Graduates of this program will be prepared to teach mathematics at the college level and to conduct research on the learning of mathematics.

ON THE TRAINING OF TEACHERS OF ADVANCED PLACEMENT COURSES

G. N. GARRISON, Wesleyan University

The continuing growth of the need for high school teachers who are prepared to teach courses in calculus stimulates this note. The program which is described below has been essentially in its present form since 1962–63.

The program is administered by the Wesleyan University Graduate Summer School for Teachers as a small (12 participants) National Science Foundation

Academic Year Institute for experienced secondary school teachers. Participants are selected on the basis of (1) an indication of their opportunity to teach advanced placement courses in the near future; (2) their ability to handle the program; and (3) their professional need for the level of instruction proposed.

The most unusual feature of the program, and the one about which we have had the most comment, is a special kind of involvement of the Institute participants in the freshman calculus course. Each participant attends all the class meetings of this course, does the assigned homework, attends the problem sessions, and takes the tests and examinations (for a grade). In addition, depending upon his instructor's estimate of his competence to do so, each participant grades about seven homework papers from each assignment for the class he attends. This is not intended as work done for the Department of Mathematics, but rather, as experience for him. Actually, other graders are available in the Department to keep the load from being excessive. Finally, again dependent upon his ability, the participant is expected to help conduct one two-hour "help session" a week to which freshmen who are having difficulties with the course can come for assistance. The rationale here, as in the grading of homework papers, is to give the high school teacher experience without actually placing him in charge of a class.

A second feature of the program, intended as support for the one just described, is a seminar in analysis for the participants. In this seminar, the topics of first-year calculus are treated with more rigor and greater precision than is usual in a freshman course.

Each high school teacher also participates in a special seminar in topics other than analysis. His program is completed with an elective chosen from the mathematics department offerings.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before January 31, 1968. Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.

E 2002 [1967, 720] **Correction.** *Proposed by F. Leuenberger, Feldmeilen, Switzerland.*

Construct a triangle ABC, having given the two sides AB and AC, and knowing that the line joining the circumcenter and the incenter is perpendicular to the interior angle bisector of angle A.

E 2006. *Proposed by A. S. Howard, Eastern Kentucky State College*

Given two fixed points A, B in the Euclidean plane, let C be free to move on a circle in the plane with A as center. Find the locus of P the point of intersection of BC with the internal bisector of angle A of the triangle ABC.

E 2007. *Proposed by W. A. Donnell, North Texas State University*

Show that a cross-cancellative (i.e., $ab=bc$ implies $a=c$) semigroup S is a cancellative semigroup.

E 2008. *Proposed by Murali Rao, University of British Columbia*

Let $\{a_n\}$ be a sequence of positive numbers such that $\sum a_n$ converges. Find a necessary and sufficient condition for the existence of a sequence of positive numbers $\{b_n\}$ such that $\sum a_n/b_n$ and $\sum b_n$ both converge.

E 2009. *Proposed by R. A. Avelsgaard and R. E. Stockton, Bemidji State College, Minnesota*

It is well known, as an example of Dirichlet's Test, that the series $\sum_{n=2}^{\infty} \sin n/\log n$ converges. Does it converge absolutely?

E 2010. *Proposed by D. R. Rao, Osmania University, India*

Show that $[(m-1)!/m]$ is even for all $m>4$. Brackets indicate the greatest integer function.

E 2011. *Proposed by R. C. Entringer, University of New Mexico*

Solve the functional equation $f(x)=f(x/(1-x))$, $x\neq 1$, subject to the condition that f is continuous at $x=0$.

E 2012. *Proposed by R. S. Kulkarni, Harvard University*

Let $f(x_1, \cdots, x_r)$, $g(y_1, \cdots, y_s)$ be two homogeneous polynomials with integral coefficients, and suppose the degree of f is relatively prime to the degree of g. Show that there exist infinitely many integral solutions of the equation $f=g$.

E 2013. *Proposed by Walter Noll, Carnegie Institute of Technology*

m, n being positive integers, prove the identity

$$S_{n,m} = \sum_{r=1}^{n} (-1)^{n-r} \sum (x_{i_1} + \cdots + x_{i_r})^m = \begin{cases} n!x_1x_2 \cdots x_n & \text{if } m = n \\ 0 & \text{if } m < n, \end{cases}$$

where the second summation is taken over all possible selections $i_1, \cdots, i_r$ of r of the first n natural numbers.

E 2014. *Proposed by Erwin Just and Norman Schaumberger, Bronx Community College, New York City*

Show that $2^{2^n}-1$ has at least n distinct prime divisors.

SOLUTIONS OF ELEMENTARY PROBLEMS

Inequalities for Two Sequences

E 1860 [1966, 199]. *Proposed by Edward Thorpe and Fred Richman, New Mexico State University*

Consider the sequences n^n, $n^{(n^n)}$, etc., and $n!$, $n!!$, $n!!!$, etc., for a fixed integer $n \geqq 3$. Do the terms of one sequence eventually become larger, and stay larger, than the corresponding terms of the other? Suppose, instead, that we compare the corresponding terms of n^n, $n^{(n^n)}$, etc., and $n!!$, $n!!!$, etc., and ask the same question.

Solution by C. B. A. Peck, Ordnance Research Laboratory, State College, Pa. Let $a_1 = n^n$, $a_{m+1} = n^{a_m}$ for $m > 0$; $b_1 = n!$, $b_{m+1} = b_m!$ for $m > 0$. We will prove

$$a_2 > 2b_2^2 (> b_2), \qquad n \geqq 2. \tag{1}$$

For $n = 2, 3, 4$, (1) is easily checked. For $n \geqq 5$,

$$\ln a_2 = n^n \ln n \text{ and } \ln 2b_2^2 = \ln 2 + 2 \ln n!!.$$

Now

$$n!! = \prod_{i=2}^{n!} i < \prod_{i=2}^{n} (i!)^{i!-(i-1)!} < \prod_{i=2}^{n} (i!)^{n!},$$

whence $\ln n!! < n! \sum_2^n \ln i!$. Also $\ln i! = \ln i + \cdots + \ln 2 < (i-1) \ln n$, so that

$$2 \ln n!! < 2n! \ln n \sum_{i=2}^{n} (i - 1) = (n - 1)n \cdot n! \ln n.$$

Thus

$$\begin{aligned} \ln 2b_2^2 &< \ln 2 + (n - 1)n \cdot n! \ln n < (n^2 - n + 1)n! \ln n \\ &< n^2 n! \ln n < n^n \ln n = \ln a_2, \end{aligned}$$

since, for $n \geqq 5$, $n^2 n! < n^n$. This implies (1).

For m, $n \geqq 2$, $b_m \geqq 2$ and for any $x \geqq 2$ it is easily seen that $x^x \geqq 2x!$. Thus for m, $n \geqq 2$, $b_m^{b_m} \geqq 2b_m! = 2b_{m+1}$. Also for m, $n \geqq 2$, $n^{b_m} > b_m$. Now suppose that $a_m > 2b_m^2$ for some m, $n \geqq 2$. (We have shown this for $m = 2$ and $n \geqq 2$.) Then

$$\begin{aligned} a_{m+1} = n^{a_m} &> n^{(2b_m^2)} = (n^{b_m})^{2b_m} > b_m^{2b_m} = (b_m^{b_m})^2 \\ &\geqq (2b_{m+1})^2 > 2b_{m+1}^2 (> b_{m+1}). \end{aligned}$$

By induction on m, $a_m > b_m$ for m, $n > 1$.

For the second question, we proceed as follows. Let $n \geqq 3$. From

$$n!! > n!(n! - 1) \cdots (n! - n) > n^{n+1} > n(n^{n-1} + 1) - 1$$

it follows that $n!! - n^n + 1 > n$, whence

$$b_3 = n!!! > n!!(n!! - 1) \cdots (n!! - n^n + 1) > n^{(n^n)} = a_2;$$

also $b_2 = n!! > n^n + n - 1 > n^n = a_1$.

Now suppose that $b_m > a_{m-1}$ for some $m \geqq 2$ for any $n \geqq 3$. (We have just shown this for $m = 2$, 3 and $n \geqq 3$.) Then $b_{m+2} = b_m!! > a_{m-1}!!$ by hypothesis; and, by problem E 1816 [1965, 902], $a_{m-1}!! > [(a_{m-1}-1)!]^{a_{m-1}!}$. Now for $m \geqq 2$ and $n \geqq 3$,

$$(a_{m-1} - 1)! \geqq (a_1 - 1)! = (n^n - 1)! > n^n - 1 > n$$

and also

$$\begin{aligned} a_{m-1}! &> a_{m-1}(a_{m-1} - 1) \cdots (a_{m-1} - n + 2) \cdots n > n^{a_{m-1}-n+1} \cdot n^{n-1} \\ &= n^{a_{m-1}} = a_m \end{aligned}$$

since $a_{m-1} - n + 2 \geqq a_1 - n + 2 = n^n - n + 2 > n^2$. Thus $b_{m+2} > a_{m-1}!! > n^{a_m} = a_{m+1}$. By induction on odd and even m separately, $b_{m+1} > a_m$ for all $m \geqq 1$ and $n \geqq 3$. (The inequality is reversed for $n = 2$ and replaced by an equality with 1 for $n = 1$.)

Also solved by the proposers.

Number of Representations

E 1862 [1966, 199]. *Proposed by Michael Fried, University of Tennessee*

Let $A = \{a_i\}_{i=1}^{\infty}$ be an ordered set of distinct positive integers. Let

$$P(x) = \prod_{i=1}^{\infty} (1 + x^{a_i}) = \sum_{i=0}^{\infty} N_A(i) x^i.$$

It is well known that $N_A(n)$ is the number of ways n can be expressed as a sum of distinct elements from A.

$N_A(n)$ is said to be unbounded if $\lim_n \sup N_A(n) = \infty$.

$N_A(n)$ is said to be uniformly unbounded if $\lim_n N_A(n) = \infty$.

(a) Find necessary and sufficient conditions on the set A so that $N_A(n) > 0$ for all n.

(b) Find necessary and sufficient conditions on the set A so that $N_A(n)$ is unbounded.

(c) Does there exist a set A for which $N_A(n)$ is unbounded but not uniformly unbounded?

Partial solution by E. S. Langford, U. S. Naval Post-graduate School, Monterey, Cal. (a) It is necessary and sufficient that $a_1 = 1$ and $a_{n+1} \leqq 1 + s_n$, where $s_n = a_1 + \cdots + a_n$. (Thus, as is well known, the 'most efficient' set is found by taking $a_n = 2^{n-1}$.) Call an integer n *attainable* if $N_A(n) > 0$.

Necessity. If for some n, $a_{n+1} > 1 + s_n$, then certainly $1 + s_n$ is not attainable.

Sufficiency. (By induction.) By definition, $s_1 = 1$ is attainable using only a_1, so assume that every integer $\leqq s_n$ is attainable using only $a_1, \cdots, a_n$. Suppose x is such that $s_n + 1 \leqq x \leqq s_{n+1}$. Since $a_{n+1} \leqq s_n + 1$, it follows that $0 \leqq x - a_{n+1} \leqq s_{n+1} - a_{n+1} = s_n$. Either $x = a_{n+1}$ or by the inductive assumption $x - a_{n+1}$ is attainable using only $a_1, \cdots, a_n$; in either case, x is attainable using only $a_1, \cdots, a_n, a_{n+1}$.

(c) Let A be the set of even positive integers. Then no odd number is attainable, so that lim inf $N_A(n)$ is 0. But evidently lim sup $N_A(n)$ is infinite.

Also solved by the proposer.

Part (b) was misstated—the proposer intended to include the restriction that $N_A(n)>0$ for all n. With this restriction, $N_A(n)$ will be unbounded iff s_n-a_{n+1} is unbounded.

Prime Power Divisors

E 1868 [1966, 309]. *Proposed by K. E. Eldridge, Ohio University*

Let p be any prime. Let t and s be integers such that $t>0$ and $0<s<p^t$. Define integer i as the exponent of the highest power of p dividing s, and integer a as the exponent of the highest power of p dividing the binomial coefficient $\binom{p^t}{s}$. Prove that $a=t-i$.

Solution by R. A. Patenaude, University of Heidelberg, Germany. Let $p^x \| y$ imply $p^x | y$ and $p^{x+1} \nmid y$. We first note that $p^x \| p^t - y$ if and only if $p^x \| y$ for $0<y<p^t$. Then

$$p^a \| \binom{p^t}{s} = \frac{(p^t)!}{s!(p^t-s)!} = \frac{p^t}{s} \prod_{j=1}^{s-1} \frac{p^t-j}{j} .$$

We are given $p^i \| s$, whence $p^a \| p^t/p^i$, and therefore $a=t-i$.

Also solved by J. C. Abad, P. N. Bajaj, M. T. L. Bizley (England), Leonard Carlitz, H. M. Edgar, M. G. Greening (Australia), F. T. Howard, Geoffrey Kandall, V. H. Keiser, Jr., Kenneth Kramer, Arthur Lieberman, J. E. MacDonald, Jr., Dan Marcus and Herrold Fischer, D. C. B. Marsh, Lieselotte Miller, Norman Miller, Wanda J. Mourant, Stanton Philipp, Stanley Rabinowitz, Perry Scheinok, R. J. Snelling, Al Somayajulu, Sidney Spital, I. Vrečko (Yugoslavia), Charles Wexler, and J. C. Williams.

Plane Subdivided by Lines

E 1869 [1966, 309]. *Proposed by J. A. Burslem, St. Louis University*

(a) Let L be a finite set of pairwise intersecting lines in the plane, and let P be the set of points determined by L. Define the multiplicity of a point $p \in P$ as the number of lines of L passing through p. For each integer $k \geq 2$, given i_k, the number of points of multiplicity k, determine the number N of regions into which L divides the plane.

(b) Do the analogous problem resulting when "great circle" and "sphere" are substituted for "line" and "plane" respectively.

Solution by Harley Flanders, Purdue University. (a) Changing slightly to more customary notation, let V be the number of vertices, E the number of edges, F the desired number ($=N$) of faces and L the number of lines which were originally placed to create this configuration. Let $V_k(=i_k)$ be the number of vertices on exactly k lines and let L_k be the number of lines on exactly k vertices. We are given only the numbers $V_k(k=2, 3, \cdots)$ and the hypothesis that no lines are parallel.

Since $V=V_2+V_3+V_4+\cdots$, the number V is determined.

Next we consider the incident triples (A, l, m) where A is a vertex and l and m are distinct lines. Counting two ways leads to

$$(*) \qquad \binom{2}{2}V_2+\binom{3}{2}V_3+\binom{4}{2}V_4+\cdots=\binom{L}{2},$$

whence L is determined.

We now count incident pairs (A, l) which gives us

$$2V_2+3V_3+4V_4+\cdots=L_1+2L_2+3L_3+\cdots.$$

But $L=L_1+L_2+L_3+\cdots$, $E=2L_1+3L_2+4L_3+\cdots$, since a line with k vertices contains $k+1$ edges. Hence $2V_2+3V_3+4V_4+\cdots=E-L$, and so E is determined.

Finally we determine F by the Euler formula in the plane,

$$V-E+F=1.$$

This gives $F=1+L+V_2+2V_3+3V_4+\cdots$, where L is given by (*).

(b) On the sphere it is easier. We have simply

$$V=V_2+V_3+\cdots, \qquad E=2V_2+3V_3+\cdots,$$

the latter by counting (vertex, edge) pairs, and $V-E+F=2$. More explicitly,

$$F=2+V_2+2V_3+3V_4+\cdots.$$

Also solved by C. P. Celenza, Michael Goldberg, Norman Miller, W. O. J. Moser, and R. J. Snelling.

Decimal Expansions with Missing Digits

E 1871 [1966, 310]. *Proposed by R. A. Jacobson, South Dakota State University*

Let $A=\{x \mid x\in[0, 1]$, and the infinite decimal expansion of x consists of not more than 9 distinct digits$\}$. Is A countable or uncountable? Find the measure of A.

I. *Solution by L. A. Steen, Saint Olaf College.* Let S_i be the subset of A consisting of all $x\in[0, 1]$ whose infinite decimal expansion does not contain the digit i $(i=0, 1, \cdots, 9)$. Then each S_i is equivalent to the set of all $x\in[0, 1]$ when represented to the base 9. Thus S_i is uncountable, and (since $S_i\subset A$) A also is uncountable.

Let the elements of S_i' (the complement of S_i) be partitioned into classes according to the earliest occurrence of the digit i and let that occurrence be in the kth place. Then the measure of the set of numbers with $k=1$ is $1/10$; with $k=2$ is $(9/10)/10$; with $k=3$ is $(9/10)^2/10$, etc. The measure of S_i' is therefore $\sum_0^\infty (9/10)^i/10=1$. Therefore S_i has measure 0. Now $A=\bigcup_{i=1}^9 S_i$, whence A has measure zero.

II. *Solution by Erwin Just, Bronx Community College.* If N is the set of normal numbers (I. Niven, *Irrational Numbers*, Carus Monograph, 1956, 94–95) then it follows from the definition of normal number that $A \cap N = \varnothing$. Since almost all real numbers are contained in N (*ibid.*, 103–104) it follows that A has zero measure.

Also solved by E. P. Emerson, G. J. Foschini, Michael Goldberg, Robert Groover III, G. A. Heuer, Edward Hook, D. H. Hutcheson, Arthur Lieberman, Daniel Marcus, Lieselotte Miller, Norman Miller, George Purdy (England), Donald Quiring, Perry Scheinok, G. F. Schumm, Stephen Soldz, Lynn A. Steen, G. B. Weiss, K. L. Yocom, and the proposer.

The result follows also from Theorem 145 of Hardy and Wright, *Introduction to the Theory of Numbers*, p. 122: *The set of points whose decimals, in any scale, miss any digit is null.*

Decimal Expansions with k Repeated Digits

E 1872 [1966, 310]. *Proposed by R. A. Jacobson, South Dakota State University*

(a) Let $U = \{x \mid x \in [0, 1]$, and at least two consecutive digits in the decimal expansion of x are identical. Find measure U.

(b) Let $V = \{x \mid x \in [0, 1]$, and at least three consecutive digits in the decimal expansion of x are identical. Find measure V.

(c) Generalize to an arbitrary base b and to k consecutive digits identical.

I. *Solution by E. P. Emerson, University of Minnesota.* Each of the sets in question has measure 1. This follows at once from Theorem 146, Hardy and Wright, *An Introduction to the Theory of Numbers*, p. 123: *Almost all decimals, in any scale, contain all possible sequences of any number of digits.*

II. *Solution by Michael Goldberg, Washington, D. C.* The numbers of the problem are normal numbers, according to the definition in Ivan Niven, *Irrational Numbers*, p. 95. On p. 103 is the theorem: *Almost all real numbers are normal to every base.* Accordingly, each of the stated sets has measure 1.

Also solved by G. J. Foschini, Erwin Just, Daniel Marcus, Lieselotte Miller, and George Purdy (England).

Defining Properties of a Group

E 1873 [1966, 310]. *Proposed by G. A. Heuer and Bruce Erickson, Concordia College*

Let S be a semigroup with cancellation. Assume that for every $a \in S$, there is an integer $n_a > 1$ such that $a^{n_a} = a$. Is S necessarily a group?

I. *Solution by J. C. Williams, Lackland Air Force Base, Texas.* Let $a, b \in S$. Since $n_a > 1$, $a^{n_a}b = a \cdot a^{n_a-1}b = ab$ implies $a^{n_a-1}b = b$. Similarly, $ba^{n_a-1} = b$. Hence a^{n_a-1} is an identity. There cannot be two identities, e and e^*, in S, since $e = e \cdot e^* = e^*$. Therefore $a^{n_a-1} = e$ for every $a \in S$. Further, if $n_a > 2$, then $a^{-1} = a^{n_a-2}$; if $n_a = 2$, then $a^2 = a = e$, so $a^{-1} = a$. Therefore S has an identity and every element has an inverse, whence S is a group.

II. *Solution by S. Lajos, Budapest, Hungary.* It is known that a regular cancellative semigroup is a group (Clifford-Preston, *The Algebraic Theory of Semigroups*, 1961, vol. I, p. 33, Ex. 5). The assumption implies solvability of the equation $axa=a$ for each a in S. Here $x=a$ if $n_a=2$, and $x=a^{n_a-2}$ when $n_a>2$. Thus S is regular and cancellative, whence by the above result, S is a group.

Also solved by R. A. Bell, E. R. Berger, W. E. Bodden, J. L. Brown, Jr., John Burslem, J. P. Celenza, R. W. Feldman, Neil Grabois, L. C. Graue, Charles Green, M. G. Greening (Australia), Thomas Hand, G. A. Heuer, R. J. Hursey, Jr., Erwin Just, R. N. Leggett, Jr., Arthur Lieberman, C. C. Lindner, D. C. B. Marsh, Lieselotte Miller, Alexander Morgan, Wanda J. Mourant, D. E. Myers, F. D. Parker, Stanton Philipp, M. S. R. K. Sastry, D. A. Sibley, D. R. Stark, Raymond, Stockton, P. K. Subramanian & L. R. Pujara, L. R. Vermani (India), Charles Wells, J. E. Wilkins, Jr., J. C. Williams, E. L. Wilson, P. R. Winter, C. N. Winton, K. L. Yocom, and the proposers.

Brown notes that if S is a finite semigroup, then cancellation alone suffices to imply that S is a group. See N. Jacobson, *Lectures in Abstract Algebra*, Vol. I, p. 24, problem 4.

Conjugate Subgroups of Order n in a Group of Order n^2

E 1874 [1966, 310]. *Proposed by W. A. McWorter, University of British Columbia*

Let G be a group of order n^2 and let H be a subgroup of order n. Prove that for any $x\in G$ we have $H\cap x^{-1}Hx\neq I$.

Solution by William Scott, University of Utah. Deny the stated conclusion, and let $K=x^{-1}Hx$. K is a subgroup of G of order n. Then

$$o(HK) = o(H)o(K)/o(H\cap K) = n^2 = o(G).$$

Hence $HK=G$ and $x=hk$, $h\in H$, $k\in K$. Thus $K=k^{-1}h^{-1}Hhk=k^{-1}Hk$, whence $H=kKk^{-1}=K$, a contradiction (unless $n=1$).

Also solved by W. E. Bodden, W. G. Dotson, Jr., L. C. Graue, M. G. Greening (Australia), Thomas Hand, Edward Hook, J. E. Joseph & C. B. Baytop, Erwin Just, Geoffrey Kandall, V. H. Keiser, Jr., Arthur Lieberman, C. C. Lindner, J. J. Martinez, Stephen Milles & Al Somayajulu, Wanda J. Mourant, Stanton Philipp, Bob Prielipp, L. R. Pujara, Simeon Reich (Israel), C. H. Sampson, M.S.R.K. Sastry, Stephen Ullom, C. N. Winton, Peter Yff (Lebanon), and the proposer.

Yff notes that, according to G. A. Miller (Annals of Mathematics, vol. 14, p. 95) the index of $H\cap x^{-1}Hx$ under H must be less than the index of H under G. This problem is a special case.

Coefficients in a Uniformly Convergent Series

E 1875 [1966, 410]. *Proposed by Samuel Zaidman, University of Montreal*

Let $\phi\in C^\infty$ $[0, 1]$ satisfy the following conditions: (1) $\phi\not\equiv 0$, (2) $\phi^{(k)}(0)=0$, $k=0, 1, 2, \cdots$, (3) The series $\sum a_k\phi^{(k)}(x)$ is uniformly convergent on $[0, 1]$ where $\{a_k\}$ is a given sequence of real numbers. Prove that $k!a_k\to 0$ as $k\to\infty$.

Solution by Stanton Philipp, University of California at Riverside. Choose $\epsilon>0$ and let $x_0\in(0, 1]$ be such that $\phi(x_0)\neq 0$. By Taylor's theorem and (2) we see that for each natural number n there is a number $\xi_n\in[0, 1]$ such that

$$\phi(x_0) = \frac{\phi^{(n)}(\xi_n)x_0^n}{n!};$$

equivalently,

(a) $$\phi^{(n)}(\xi_n) = n!\phi(x_0)/x_0^n.$$

By (3), there is a natural number N such that if $n>N$, then

(b) $$|\, a_n\phi^{(n)}(\xi_n)\,| < \epsilon|\,\phi(x_0)\,|\,.$$

Substituting from (a) into (b), we have for every $n>N$,

$$\left|\frac{a_n n!\phi(x_0)}{x_0^n}\right| < \epsilon|\,\phi(x_0)\,| \Rightarrow |\,n!a_n\,| < \epsilon x_0^n \leqq \epsilon.$$

Also solved by A. S. Galbraith, C. H. Sampson, Al Somayajulu & Steve Milles, Sidney Spital, and the proposer.

Ratios of Number Theoretic Functions

E 1876 [1966, 410]. *Proposed by K. K. Norton, University of Illinois*

Let $\phi(n)$ be Euler's totient function, let $d(n)$ be the number of divisors of n, and let $\sigma(n)$ be the sum of those divisors. Show that

(1) $$\liminf_{n\to+\infty}\frac{\phi(n)}{nd(n)} = \liminf_{n\to+\infty}\frac{\sigma(n)}{nd(n)} = 0,$$

(2) $$\limsup_{n\to+\infty}\frac{\phi(n)}{nd(n)} = \limsup_{n\to+\infty}\frac{\sigma(n)}{nd(n)} = \frac{1}{2}.$$

Solution by R. B. Eggleton, Avondale College, Cooranbong, Australia. All the functions concerned are multiplicative, so it is sufficient to consider the case $n=p^k$, where p is prime and k any positive integer. Familiar formulas for ϕ, d and σ give

$$\frac{\phi(p^k)}{p^kd(p^k)} = \frac{p^{k-1}(p-1)}{p^k(k+1)} = \frac{p-1}{p(k+1)} \to \begin{cases} 1/(k+1) & \text{as } p\to\infty \text{ if } k \text{ is fixed;} \\ 0 & \text{as } k\to\infty \text{ if } p \text{ is fixed.} \end{cases}$$

$$\frac{\sigma(p^k)}{p^kd(p^k)} = \frac{p^{k+1}-1}{p^k(p-1)(k+1)} \to \begin{cases} 1/(k+1) & \text{as } p\to\infty \text{ if } k \text{ is fixed;} \\ 0 & \text{as } k\to\infty \text{ if } p \text{ is fixed.} \end{cases}$$

The appropriate results follow, by taking $k=1$ and $p\to\infty$ for the suprema, and p fixed with $k\to\infty$ for the infima.

Also solved by Anders Bager (Denmark), P. N. Bajaj, Gabriel Bastien, Addison Fischer, M. G. Greening (Australia), Emil Grosswald, R. E. Giudici, R. J. Hursey, Jr. & Charles Zeigenfus, Betty Kvarda, E. S. Langford, Arthur Lieberman, Dan Marcus, D. C. B. Marsh, Stanton Philipp, Simeon Reich (Israel), Sister Marion Beiter, R. Sivaramakrishnan (India), Al Somayajulu, Sidney Spital, and A. M. Vaidya (India).

Convex Pentagon Inscribed in a Semicircle

E 1877 [1966, 410]. *Proposed by Huseyin Demir, Middle East Technical University, Ankara, Turkey*

Let $ABCDE$ be a convex pentagon inscribed in a unit circle with AE as diameter, and let $AB=a$, $BC=b$, $CD=c$, $DE=d$. Then prove that

$$a^2 + b^2 + c^2 + d^2 + abc + bcd < 4.$$

Solution by Allan Wachs, Student at Far Rockaway (N. Y.) High School. Draw AC and CE and put $\theta = \sphericalangle CEA$. Then $\sphericalangle CAE = 90° - \theta$, $\sphericalangle CBA = 180° - \theta$, $\sphericalangle CDE = 180° - (90° - \theta) = 90° + \theta$. By the law of cosines,

$$(1) \qquad AC^2 = a^2 + b^2 - 2ab \cos (180° - \theta) = a^2 + b^2 + 2ab \cos \theta,$$

$$(2) \qquad CE^2 = c^2 + d^2 - 2cd \cos (90° + \theta) = c^2 + d^2 + 2cd \sin \theta.$$

From the right triangle ACE, $AC^2 + CE^2 = AE^2 = 4$, also $AC = 2 \sin \theta > b$ and $CE = 2 \cos \theta > c$ (because of the obtuse angles). Substitution of these results into the sum of (1) and (2) gives at once

$$4 > a^2 + b^2 + c^2 + d^2 + abc + bcd.$$

Also solved by Leon Bankoff, W. J. Blundon, L. Carlitz, Mannis Charosh, M. A. Ettrick, Michael Goldberg, M. G. Greening (Australia), Ned Harrell, Donald Jeffords, Erwin Just, J. D. E. Konhauser, Dan Marcus, Lieselotte Miller, Norman Miller, C. B. A. Peck, Al Somoyajulu, J. L. Standig, C. S. Venkataraman (India), J. C. Williams, Dale Woods, and the proposer.

Concyclic Points within a Regular Polygon

E 1878 [1966, 410]. *Proposed by Huseyin Demir, Middle East Technical University, Ankara, Turkey*

Let $A_1A_2 \cdots A_n$ be a regular polygon inscribed in circle (O) of radius R. Denote the incenter of the triangle $A_{i-1}A_iA_{i+1}$ (indices mod n) by I_i, and that of the triangle formed by A_iA_{i+2}, $A_{i+2}A_{i+1}$, $A_{i+1}A_{i+3}$ by J_i. Then show that the points $I_1, \cdots, I_n$ and $J_1, \cdots, J_n$ all lie on the same circle of radius $R' = R \cos (3\pi/2n)/\cos (\pi/2n)$.

Solution by Frank Kerr, Napa, California. Let the intersection of $A_{i-1}A_{i+1}$ with OA_i be P_i and that of $A_{i+1}A_{i+2}$ with line OJ_i be Q_i. Then

$$\begin{aligned} OI_i &= OP_i + P_iI_i \\ &= R \cos (2\pi/n) + R \sin (2\pi/n) \tan (\pi/2n) \\ &= R[2 \cos (2\pi/n) \cos (\pi/2n) + 2 \sin (2\pi/n) \sin (\pi/2n)]/2 \cos (\pi/2n) \\ &= R \cos (3\pi/2n)/\cos (\pi/2n), \end{aligned}$$

and

$$\begin{aligned} OJ_i &= OQ_i - Q_iJ_i \\ &= R\cos(\pi/n) - R\sin(\pi/n)\tan(\pi/2n) \\ &= R[2\cos(\pi/n)\cos(\pi/2n) - 2\sin(\pi/n)\sin(\pi/2n)]/2\cos(\pi/2n) \\ &= R\cos(3\pi/2n)/\cos(\pi/2n). \end{aligned}$$

Hence $R' = OI_i = OJ_i = R\cos(3\pi/2n)/\cos(\pi/2n)$.

Also solved by J. P. Celenza, Michael Goldberg, M. G. Greening (Australia), J. D. E. Konhauser, E. S. Langford, Dan Marcus, D. C. B. Marsh, Lieselotte Miller, Norman Miller, Robert Patenaude (Germany), J. M. Quoniam (France), Simeon Reich (Israel), Stephen Spindler, Sidney Spital, C. S. Venkataraman (India), and the proposer.

A Billiard Table Problem

E 1879 [1966, 411]. *Proposed by Agatha Himmelfarb, Fordham University*

A billiard ball is cued from a corner of an $n\times m$-foot billiard table at an angle of 45° (n and m are integers). How many cushions will the ball strike before it again goes into a corner?

Solution by D. L. Silverman, Hughes Aircraft Company, El Segundo, Calif. Tesselate the first quadrant with $m\times n$ rectangles. By reflection, each boundary intersected by the line $x=y$ corresponds to a cushion struck by a ball cued from the origin at a 45° angle. The line $x=y$ first intersects a vertex at (L, L), where L is the lowest common multiple of m, n, and en route intersects $L/n-1$ vertical and $L/m-1$ horizontal boundaries. Accordingly, the ball strikes $L/n+L/m-2=(m+n)L/mn-2$ cushions. The result may also be written $(m+n)/(m, n)-2$, where $(,)$ indicates the greatest common divisor.

Also solved by J. C. Abad, Merrill Barneby, J. A. Byrd, J. P. Celenza, Yu Chang, R. B. Eggleton (Australia), Michael Goldberg, Michael Goodman, M. G. Greening (Australia), H. S. Hahn, G. A. Heuer, Donald Jeffords, Michael Goldberg, R. S. Kaluzniacki, R. L. Kammerer, M. S. Kaplan, Frank Kerr, M. S. Klamkin, M. S. Knebelman, Kenneth Kramer, E. S. Langford, Dan Marcus, D. C. B. Marsh, Lieselotte Miller, Norman Miller, Edward Moylan, F. D. Parker, Robert Patenaude (Germany), C. B. A. Peck, Stanton Philipp, J. M. Quoniam (France), Steven Russ, J. J. Segedy, K. N. Sigmon, T. R. Smith, Stephen Spindler, Lawrence Somer, Paul Sugarman, Stephen Tice, P. S. Viita, Allan Wachs, John Wessner, Oswald Wyler, J. W. Zerger, and the proposer.

Klamkin notes that the problem is not new and that a generalization appeared in the 1959 fall edition of the Pi Mu Epsilon Journal. See also problem E 1704 [1965, 669] for a related result.

Marsh notes a second interpretation of the problem; since the table has at most four cushions to be hit, the number of different cushions struck during the ball's motion will be

0 if $q=p=1$, $q=n/(m,n)$, $p=m/(m,n)$;
1 if q, $p=2$, 1 in either order;
2 if one of q, p is 1 and the other is >2;
3 if the smaller of q, p is 2;
4 if the smaller of q, p is >2.

ADVANCED PROBLEMS

All solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before March 31, 1968. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose a self-addressed stamped postcard.

5510. *Proposed by M. L. Glasser, Battelle Memorial Institute, Columbus, Ohio*

Show that

$$\sum_{k=-\infty}^{\infty} (-1)^k(x + kz) \exp(-k^2z^2/x) \cdot {}_1F_1[\tfrac{1}{2}, \tfrac{3}{2}; (x + kz)^2/x] = 0.$$

Does this generalize to other hypergeometric functions?

5511. *Proposed by R. S. Kulkarni, Harvard University*

Characterize groups of order $2n$ which contain exactly n elements of order 2 (i.e. $a^2=1$, $a\neq 1$). (Note that the symmetry group of a polygon with an odd number of sides has this form.)

5512. *Proposed by M. F. Neuts, Purdue University*

At time O an urn contains N balls ($N \geqq O$). Every time unit later, k balls are added and immediately thereafter, (i.e., at times $n+O$), r balls are drawn out at random and discarded ($O<r<k$).

1. What is the probability that a particular ball which is in the urn at time $n+\frac{1}{2}$ will be thrown out later than time $n+\nu+O$? $\nu=1, 2, \cdots$.

2. What is the probability that a particular ball will eventually be thrown out?

3. What is the expected number of drawings required before the given ball is thrown out?

5513. *Proposed by L. F. Meyers, Ohio State University*

If a is a real number and S is a subset of the set R of all real numbers, then the translate T_aS of S by a is defined to be $\{x+a : x \in S\}$. For certain subsets S of R it is possible to find a real number a such that T_aS is the complement S' of S in R. For example, if $S=\bigcup_{k=-\infty}^{\infty}[2k, 2k+1)$, then the translate of S by each odd integer is S'. For each set S allowing a translation onto its complement, let

$$f(S) = \inf\{a : a > 0 \text{ and } T_aS = S'\}.$$

In the above example, $f(S)=1$. Is it possible to find a set S such that $f(S)=0$? In other words, is there a subset of the real line which admits arbitrarily small nontrivial translations of itself onto its complement?

5514. *Proposed by J. W. Wyman, Pasadena College, California*

Find all positive valued functions defined on the positive real numbers such that $ab \leqq \frac{1}{2}\{af(a)+bf^{-1}(b)\}$ for every $a>0$, $b>0$.

5515. *Proposed by J. W. Wyman, Pasadena College, California*

Let f: $M_1 \to M_2$, where M_1 and M_2 are metric spaces, and define f to be *absolutely continuous* if for each $\epsilon>0$, there exists $\delta>0$ such that if $\{a_1, \cdots, a_n\}$ is any finite set of points of M_1 such that $\sum_{i=1}^{n-1} d(a_i, a_{i+1})<\delta$, then $\sum_{i=1}^{n-1} d(f(a_i), f(a_{i+1}))<\epsilon$. If f is continuous, do there exist metrics equivalent to the given metrics in M_1 and M_2 respectively such that f is absolutely continuous with respect to those metrics?

5516. *Proposed by D. J. Simanaitis and L. R. Anderson, Western Reserve University*

Let E be a nonzero unitary K-module which is generated by one element. Suppose the annihilator of E in K is $\{0\}$. Prove or disprove: E admits a basis.

5517. *Proposed by W. A. McWorter, University of British Columbia*

Let $\bigcirc$ be a relation on a set X. A subset A of X is said to be a kernel of $\bigcirc$ if (1) $x \not\bigcirc y$ for every x, y in A, and (2) for every x not in A, there is a y in A such that $x \bigcirc y$.

Suppose $\bigcirc$ is such that for every nonempty subset B of X there is an x in B such that $x \not\bigcirc b$ for every b in B. Prove that $\bigcirc$ has a unique kernel.

5518. *Proposed by P. J. Schweitzer, Institute for Defense Analyses, Arlington, Va.*

Let $a_k=\sum_{i=1}^{n}(x_i)^k$, $k=1, 2, \cdots$. Show that a_k, $(k=n+1, n+2, \cdots)$ can be expressed as a polynomial in $a_1, a_2, \cdots, a_n$. Stated differently, show that the traces of the higher powers of an $n \times n$ matrix can be expressed as polynomials in the traces of the first n powers.

5519. *Proposed by W. O. Egerland, U.S.A. Nuclear Defense Laboratory, Edgewood Arsenal, Md.*

Let $\sum_{n=1}^{\infty} a_n z^n$ be a power series in $z=x+iy$, $|a_n| \leqq cn^p$, c and p positive constants. Determine

$$\lim_{n\to\infty} n^{\alpha} \iint_{|z|\leqq 1} \log(1+|a_n z^n|)\,dxdy$$

for every $\alpha<1$.

SOLUTIONS OF ADVANCED PROBLEMS

A Functional Equation of Bernoulli

5410 [1966, 782]. *Proposed by H. W. Guggenheimer, University of Minnesota*

Prove that $x^{k+1}y(x^{-k}) = y(x)$, $x>0$, has no analytic nontrivial $(y(x) \neq x)$ solution for $k \neq 1$. (This functional equation was proposed by John Bernoulli in 1696, but no valid discussion seems to have been given.)

Solution by Robert Breusch, Amherst College. Let k be real, $k \neq \pm 1$. Then there cannot even be a solution which is just continuous for $x>0$ (actually continuous only for $x=1$).

Let $f(x) = y(x)/x$. Then the problem asks for continuous solutions of

$$\text{(A)} \qquad f(x) = f(x^{-k}), \qquad f(x) \neq a \text{ (a constant)}, \qquad k^2 \neq 1.$$

By (A), $f(x) = f(x^{k^2}) = f(x^{k^4}) = \cdots = f(x^{k^{2n}}) = \cdots$, and $f(x) = f(x^{k^{-2}}) = f(x^{k^{-4}}) = \cdots = f(x^{k^{-2n}}) = \cdots$.

Let $f(1) = c$ and $k^2 < 1$. Then $\lim_{n\to\infty} x^{k^{2n}} = 1$ for every $x>0$, thus by continuity $f(x) = \lim_{n\to\infty} f(x^{k^{2n}}) = f(1) = c$ which contradicts (A).

If $f(1) = c$ and $k^2 > 1$, the same contradiction develops from the fact that $\lim_{n\to\infty} x^{k^{-2n}} = 1$ for every $x>0$.

Also solved by D. R. Anderson, D. Ž. Djoković (Yugoslavia), L. Dorembus & S. Rosset (Israel), D. A. Hejhal, M. D. Mavinkurve (India), R. H. C. Newton (Australia), Stephen Soldz, P. C. Tonne, and the proposer.

Tonne extended the problem and noted for a very general class of functions $u(x)$, $|u'(1)| \neq 1$, $u(1) = 1$, that the analytic solutions of $xu(x)y(1/u(x)) = y(x)$ have the form $y(x) = cx$.

Groups with Direct Factor Subgroups

5411 [1966, 782]. *Proposed by Azriel Rosenfeld, University of Maryland*

Let G be a group every subgroup of which is a direct factor of G. Prove that G is a direct product of cyclic groups of prime orders.

Solution by R. W. Gilmer, Jr., Florida State University. We first observe that G is abelian. For, if $g \in G$, $G = (g) \oplus H$ for some subgroup H of G; g commutes with each element of H, and hence commutes with each element of G.

Zorn's lemma implies the existence of a maximal independent subset $S = \{s_\alpha\}$ of G. If T is the subgroup of G generated by S, we show $T = G$. By hypothesis, T is a direct factor of G: $G = T \oplus H$. And for any nonidentity element h of H, $S \cup \{h\}$ is independent. The maximality of S then implies H is the trivial subgroup of G and $G = T$. Hence G is the direct product of the collection $\{(s_\alpha)\}$ of cyclic groups generated by elements of S.

To complete the proof we show that each (s_α) is a direct product of cyclic groups of prime order.

For this purpose, we first prove that if H is a subgroup of G and if J is a subgroup of H, then J is a direct factor of H. By assumption, J is a direct factor of G: $G=J\oplus T$, and the modular law then implies that $H=J\oplus(H\cap T)$. In particular, if $g\in G$, each subgroup of (g) is a direct factor of (g). From the known structure of cyclic groups, it follows that if (g) is nontrivial, then the order of (g) is finite and is a product of distinct prime factors. Hence (g) is a direct product of cyclic groups of prime order, which completes the proof.

Also solved by M. R. Alipour (Iran), Frank Cannonito, D. Ž. Djoković (Yugoslavia), S. J. Farber & Marvin Tretkoff, P. Hantom, G. A. Heuer, Geoffrey Kandall, H. D. Keesing, M. D. Mavinkurve (India), Ka Menehune, Al Somayajulu, Gomer Thomas, Z. Z. Uoiea, R. Wiegandt (Hungary), Kenneth Yanosko, and the proposer.

Kandall and Wiegandt refer to a theorem of A. Kertész: *Each subgroup of a group G is a direct factor of G if and only if G is abelian and the order of each element of G is a squarefree number.* See A. Kertész, *On groups every subgroup of which is a direct summand*, Publ. Math. Debrecen, 2 (1951) pp. 74–75.

The Magnitude of Least Common Multiples

5412 [1966, 783]. *Proposed by Paul Erdös, Budapest, Hungary*

Let $a_1<a_2<\cdots$ be an infinite sequence of integers. Put A_n for the least common multiple of $a_1, a_2, \cdots, a_n$. Prove that $A_n>n^{c_1 \log\log n}$, but that there is a sequence $a_1<a_2<\cdots$ so that $A_n<n^{c_2 \log\log n}$.

Solution by J. H. van Lint, Technological University, Eindhoven, Netherlands. (a) Let $d(A_n)$ be the number of divisors of A_n. Trivially $n\leqq d(A_n)$. Now for every $\epsilon>0$ and m sufficiently large

$$d(m) < \exp\left\{(1+\epsilon)\log 2\frac{\log m}{\log\log m}\right\}$$

(cf. Prachar, *Primzahlverteilung*, p. 24). It follows that $\log A_n>c_1(\log n)(\log\log n)$ with a positive constant c_1 so that $A_n>n^{c_1 \log\log n}$.

(b) Let $P_i=\Pi_{p\leqq 3^i} p$. Then $P_i>(P_{i-1})^2$ and therefore P_i has at least $\frac{1}{2}\cdot 2^{\pi(3^i)}$ divisors which are greater than P_{i-1}. Let the sequence $\{a_n\}$ consist of these numbers; i.e., $\{a_n\}$ is the sequence of numbers larger than P_{i-1} and dividing P_i for some i, which is the sequence 1, 2, 3, 6, 7, 10, 14, $\cdots$. If $P_{\nu-1}<a_n\leqq P_\nu$, then $A_n\leqq P_\nu$, i.e., $\log A_n=O(3^\nu)$.

Furthermore $n>\frac{1}{2}\sum_{i=1}^{\nu-1} 2^{\pi(3^i)}$, i.e.,

$$\frac{\log n}{\log 2} > \frac{3^{\nu-1}}{(\nu-1)\log 3} - 1$$

from which we see $3^\nu=O(\log n\cdot\log\log n)$. This means that for the sequence considered we have $\log A_n=O(\log n\cdot\log\log n)$ completing the proof.

Also solved by Dieter Wolke (Marburg, Germany) who uses the sequence $\{a_i\}$ defined as follows: $n \in \{a_i\}$ if and only if $\mu(n \neq 0$ and $p(n) \geqq (7/2) \log n$, where $p(n)$ is the largest prime divisor of n.

A Pair of Singular Double Integrals

5414 [1966, 783]. *Proposed by L. Carlitz, Duke University*

Show that

$$(1) \quad \int_0^1 \int_0^1 \{(1-x^2)(1-y^2)(1-x^2y^2)\}^{-1/2} dxdy = \frac{(\Gamma(\frac{1}{4}))^4}{16\pi}.$$

$$(2) \quad \int_0^1 \int_0^1 \{(1-x^2)(1-y^2)(1+x^2y^2)\}^{-1/2} dxdy = \frac{\pi^2}{4} \left\{\frac{\Gamma(9/8)}{\Gamma(5/4)\Gamma(7/8)}\right\}^2.$$

I. *Solution by R. E. Shafer, University of California at Livermore.* A more general pair of integrals are

$$\int_0^1 \int_0^1 x^{4a-1}y^{2a-1/2}\{(1-x^2)(1-y^2)(1 \mp x^2y^2)\}^{-1/2} dxdy$$

with Re $(a) > 0$. Expanding $(1 \mp x^2y^2)^{-1/2}$ by the binomial theorem and integrating termwise, we obtain

$$\frac{\pi}{4} \frac{\Gamma(2a)\Gamma(a+1/4)}{\Gamma(2a+1/2)\Gamma(a+3/4)} \cdot {}_3F_2[1/2, 2a, a+1/4; 2a+1/2, a+3/4; \pm 1]$$

which is reducible, using Clausen's theorem (Erdelyi, *Higher Transcendental Functions*, vol. 1, Section 4.3) into

$$\frac{\pi}{4} \frac{\Gamma(2a)\Gamma(a+1/4)}{\Gamma(2a+1/2)\Gamma(a+3/4)} \{{}_2F_1[1/4, a; a+3/4; \pm 1]\}^2$$

which may be readily evaluated by Gauss' identity. Therefore

$$\int_0^1 \int_0^1 x^{4a-1}y^{2a-1/2}\{(1-x^2)(1-y^2)(1-x^2y^2)\}^{-1/2} dxdy = \frac{\Gamma(a)\{\Gamma(1/4)\}^2 2^{-7/2}}{\Gamma(a+1/2)};$$

$$\int_0^1 \int_0^1 x^{4a-1}y^{2a-1/2}\{(1-x^2)(1-y^2)(1+x^2y^2)\}^{-1/2} dxdy = \frac{\pi}{32} \frac{\Gamma(a/2)\Gamma(a/2+1/4)}{\Gamma(a/2+1/2)\Gamma(a/2+3/4)}.$$

II. *Solution by M. L. Glasser, Battelle Memorial Institute.* The integrals are the case $\alpha=\beta=\frac{1}{2}$, $\gamma=1$ of the formula

$$\int_0^1\int_0^1 x^{2(\alpha-\gamma)+1}y^{2\beta-1}[(1-x^2)(1-y^2)]^{\gamma-\beta-1}(1\pm x^2y^2)^{-\alpha}dxdy$$

$$= \tfrac{1}{4}B(\beta,\gamma-\beta)\begin{cases}\dfrac{\Gamma(\gamma-\beta)\Gamma(\alpha-\gamma+1)}{\Gamma(\alpha-\beta+1)}\,{}_3F_2\left[\begin{matrix}\alpha-\gamma+1,\ \alpha,\ \beta\\ \alpha-\beta+1,\ \gamma\end{matrix}\,\middle|\,-1\right],\\ \dfrac{\Gamma(1+\alpha/2)\Gamma(\gamma)\Gamma(\alpha-\gamma+1)\Gamma(\gamma-\alpha/2-\beta)}{\Gamma(1+\alpha)\Gamma(1+\alpha/2-\beta)\Gamma(\gamma-\alpha/2)}, \text{ Re } (\gamma-\alpha/2-\beta)>0,\end{cases}$$

for Re $(\gamma-\beta)>0$, Re $(\alpha-\gamma+1)>0$.

This formula is obtained, after a simple change of variables, by combining equations 7.512 (1), (12) and 9.111 of Gradshteyn and Ryzhik, *Table of Integrals, Series and Products* (Academic Press, 1965). The generalized hypergeometric series arising in this case can be found, e.g., in Bailey, *Generalized Hypergeometric Series* (Cambridge, 1935).

Also solved by M. G. Beumer, D. A. Breault, J. H. Heinbockel, E. L. Koh, Chih-Bing Ling, J. W. Mellender, F. W. Steutel (Netherlands), the late E. L. Whitney, V. E. Wood, and the proposer.

Breault obtains the first formula above from problem 612, Mathematics Magazine, Sept.–Oct. 1966, pp. 251 ff.

Whitney avoids hypergeometric series by establishing the first integral as $\frac{1}{2}\pi\int_0^1 F(x^2)(1-x^2)^{-1}dx$ and the second as $\frac{1}{2}\pi\int_0^1 xF(x^4)(1-x^2)^{-1/2}dx$, where

$$F(r^2)=\frac{1}{\pi}\int_0^\pi \frac{d\theta}{\sqrt{1+r^2+2r\cos\theta}}=\frac{2}{\pi}\int_0^{\frac{1}{2}\pi}\frac{d\theta}{\sqrt{(1+r)^2-4r(\sin\theta)^2}}.$$

Primitive Elements for K/Q

5416 [1966, 783]. *Proposed by W. J. Leahey, University of Illinois*

Let K be a number field and θ a primitive element for K/Q, i.e. $K=Q(\theta)$, where Q is the field of rational numbers. Let $f(X)$ be the minimal polynomial of θ over Q and denote by $f'(X)$ the derivative of $f(X)$. Is $f'(\theta)$ necessarily a primitive element for K/Q?

Solution by L. Carlitz, Duke University. Consider $f(x)=x^6-2x^3+2$, which is evidently irreducible over Q (by the Eisenstein criterion). Then for $f(\theta)=0$,

$$\begin{aligned}\delta &= f'(\theta) = 6(\theta^5-\theta^2) = 6\theta^2(\theta^3-1),\\ \delta^2 &= 36\theta^4(\theta^3-1)^2 = 36\theta^4(\theta^6-2\theta^3+1) = -36\theta^4,\\ \delta^3 &= -216\theta^3(\theta^6-\theta^3) = -216\theta^3(\theta^3-2)\\ &= -216(\theta^6-2\theta^3) = 2\cdot 6^3,\end{aligned}$$

so that δ is not a primitive element of K.

A Multivariate Distribution

5417 [1966, 783]. *Proposed by M. V. Chari and John Slivka, State University of New York at Buffalo*

Show that $\int \cdots \int_S (y-z)dx_1 \cdots dx_r = m-n$, where $y = \min_i\{m,\ x_i+\frac{1}{2}\}$, $z = \max_i\{n,\ x_i-\frac{1}{2}\}$, $n<m$, and

$$S = \{(x_1, \cdots, x_r);\ n - \tfrac{1}{2} < x_i < m + \tfrac{1}{2} \text{ for all } i (i = 1, \cdots, r) \text{ and } \max_i\{x_i\} - \min_i\{x_i\} < 1\}.$$

Solution by the proposers. Consider the statistical joint density

$$f(w, x_1, \cdots, x_r) = \begin{cases} 1/(m-n), & n < w < m,\ w - \frac{1}{2} < x_i < w + \frac{1}{2} \text{ for all} \\ 0, & \text{elsewhere.} \end{cases}$$

$$= \begin{cases} 1/(m-n), & z < w < y \\ 0, & \text{elsewhere.} \end{cases}$$

Finding the marginal density of $x_1, \cdots, x_r$ we have

$$g(x_1, \cdots, x_r) = \begin{cases} \dfrac{y-z}{m-n}, & (x_1, \cdots, x_r) \in S \\ 0, & \text{elsewhere,} \end{cases}$$

from which the desired result follows immediately.

Rank in a Symmetric Semi-definite Matrix

5419 [1966, 784]. *Proposed by F. D. Faulkner, U. S. Naval Postgraduate School*

Let A_{nn} be a real, symmetric, positive semi-definite matrix. Let A_{pn} be the matrix obtained from A_{nn} by omitting the last $n-p$ rows, and A_{pp} be obtained by omitting the last $n-p$ columns of A_{pn}. Prove that rank A_{pp} = rank A_{pn}.

I. *Solution by R. F. Rinehart, Naval Postgraduate School.* Since A is positive semidefinite, there exists a matrix C such that $C^TC = A$. Let

$$P = \begin{pmatrix} I_{n-p} & 0 \\ 0 & 0 \end{pmatrix}$$

and let $R(X)$ signify rank of X. Then by well-known rank theorems, including the theorem that $R(X^TX) = R(X)$, for X real,

$$R(A_{pn}) = R(P^TA) \geqq R([P^TA]P) = R(A_{pp})$$
$$= R(P^TC^TCP) = R(P^TC^T) \geqq R(P^TC^TC) = R(A_{pn}).$$

Therefore $R(A_{pn}) = R(A_{pp})$.

II. *Solution by W. L. Morris, Oak Ridge National Laboratory.* Remark:

Denoting rank by R, it is well known that $R(CD)=R(D)$ if and only if $CDx=0$ implies $Dx=0$. (Mirsky: *An Introduction to Linear Algebra*, p. 165.)

Let A be a nonnegative hermitian matrix and S a matrix of p columns and n rows. We prove the (slightly) more general result: $R(S^HAS)=R(S^HA)$, where the superscript H denotes the conjugate transpose. If $S^HASx=0$ then $(Sx)^HA(Sx)=0$ which implies that either (1) $Sx=0$ or (2) $(Sx)^HA(Sx)/(Sx)^H(Sx)=0$. If (2) holds then Sx minimizes the Rayleigh quotient of A which means that Sx is a proper vector of A associated with its smallest proper value, viz., zero (Gantmacher, *The Theory of Matrices*, vol. 1, p. 319). In either case, $S^HASx=0$ implies $ASx=0$. Applying the remark gives $R(S^HAS)=R(AS)$, and since A is hermitian, $R(AS)=R(S^HA)$. Taking S to be the first p columns of the identity solves the problem.

Also solved by D. Ž. Djoković (Yugoslavia), A. S. Householder, M. D. Mavinkurve (India), C. C. A. Sastri, G. W. Soules, and the proposer.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto 5, Canada. Correspondence about Reviews will be welcome.

Reviewing Policy. We are now publishing telegraphic reviews of all textbooks above the sophomore level and of all other mathematics books, including many advanced treatises, thought to be of interest to the readers of this magazine. The lag between receipt of books and publication is about three months, of which more than two are accounted for by the mechanics of printing and distribution. This coverage, in spite of the use of small type, requires a high selectivity of titles for extended review. We solicit comments and suggestions.

The problem of reviewing textbooks in fairly standard courses is a most difficult one. We feel that the most important thing is a prompt informative notice, since professors make their choices only after examining the book itself. Accordingly, telegraphic reviews are intended to give sufficient information for a decision as to whether to order an examination copy. An extended review of a textbook by someone who has not used it is of doubtful value, especially if it is delayed by a year or more, and such reviews in the past have served often as nothing more than belated notices. On the other hand, a review based on actual use would be valuable. We have tried to arrange for such reviews by locating and soliciting users. However, we have had little success during the current year, largely because of the difficulty of finding a professor who had actually used a given book. Perhaps the best way to secure reviews of this kind is to ask for volunteers. In order to avoid unintentional duplications we ask that those willing to review give us advance notice of their intentions.

Perhaps even more valuable than reviews of individual books would be survey articles analyzing the existing textbooks in a given area. Such articles would be helpful to the professor faced with an overwhelming number of competing textbooks among which it is difficult to distinguish without extended study. This type of a survey article

would be a substantial job, but much of such work is done by those assigned to choose textbooks. We hope that volunteers will let us know of their willingness to perform this valuable service to the profession, and we stand ready to help secure the books.

Universal Algebra. By P. M. Cohn. Harper and Row, New York, 1965. xi+333 pp. $9.75 (Teleg. Review April 1967).

Given a set A together with a set Ω of functions from Cartesian powers of A to A. If Ω can be partitioned into disjoint subsets $\Omega(0), \Omega(1), \cdots$ (some of which may be empty) such that each element of $\Omega(n)$ is a function from A^n to A, then the pair $\langle A, \Omega\rangle$ constitutes a *universal algebra*. The elements of $\Omega(n)$ are the n-ary operations of $\langle A, \Omega\rangle$. The 0-ary operations are interpreted as distinguished elements. Thus a group can be presented as a universal algebra with one 0-ary operator the identity, one unary operation inversion, and one binary operation product. There is no restriction on the cardinality of Ω, so that it is possible to view a vector space over the real field as a universal algebra with, among others, an infinite set of unary operations: the scalar multiplications

$$\theta_r\colon x \to rx$$

for each real number r.

The history of Universal Algebra began with a work of A. N. Whitehead, a Treatise on Universal Algebra with Applications I, Cambridge 1898, from which the subject got its name. Whitehead in his treatise attempted to produce a unified treatment of Hamilton's quaternions, Grassmann's calculus of extensions, and Boole's algebra of logic, which were the main algebraic systems extant at the time. The term "applications" in the title of his Treatise refers to applications to geometry and mechanics.

After Whitehead, the subject lay dormant until the early 1930's when it was taken up by G. Birkhoff and O. Ore. Each of these authors published papers on universal algebras which employed algebraic concepts and the somewhat crude metamathematical apparatus available at the time.

The main result of Birkhoff (part of Theorem 3.1 p. 169 in the book under review) gives a flavour of the results of that time: If the axioms of a set of universal algebras can be presented in the form of equations without quantifications, then the set is closed under the formation of direct products, homomorphisms, and subalgebras.

The refinements in metamathematics and category theory which were made in the 1940's and early 50's paved the way for the further development of universal algebra. This began with A. Robinson's *On the metamathematics of algebra* in 1951; later it was continued by Tarski, Mostowski, and their students, until today there is a flourishing literature on the subject. Much of the present day work in universal algebra involves the theory of models developed by Robinson. His most famous result, developed within this theory (Corollary 6.8 p. 219) is the following: An elementary sentence (a formula without free variables) which holds in every field of characteristic zero also holds in every field of sufficiently high characteristic.

The book under review is, to the reviewer's knowledge, the first book since Whitehead's which is devoted entirely to the subject in full generality, and therefore it deserves some attention. It has already been reviewed in the Math. Reviews by J. R. Isbell (MR 31, no. 224) and in the J. London Math. Soc. by Graham Higman (41 (1966), 760).

Since Isbell's review covers the content quite adequately, I will not detail a list of the subject matter covered. Instead, I shall concentrate on the relevance to mathematics of the subject as a whole and of the book in particular. In his review, Higman remarks: "Universal Algebra is something everyone ought to know about, though nobody should specialize in it." To a large extent this is also the present reviewer's opinion. To develop a new argument or result in, say, group theory and then to generalize it to a wider class

of universal algebras, puts a result of proven utility at the disposal of workers studying algebras of this wider class, and hence is a useful contribution to mathematics. On the other hand, to obtain a result about universal algebras as such, without reference to an application, may result in yet another hollow addition to the already overblown mathematical literature.

The book under review is concerned with results of the former kind, i.e. standard results and arguments given in their broadest generality and results proved in a general setting which have obvious application to well-known problems. The reader with a year of graduate work in algebra will find the book a compendium of familiar arguments and proofs arranged in such a way that it is easy for him to fit them into algebra (and mathematics) as a whole. In general, I would say that the book could be used as a basis for a first or perhaps second year graduate course in algebra, for those interested in the relationship between abstract algebra and the foundations of mathematics.

A word of caution is necessary however: The style of the book is very condensed; in fact, in places it is genuinely heavy going. Some of the results are stated very cleverly, as for example Proposition 4.1 on p. 21 where you are tempted to provide a counter-example before you realize that the infimum of the empty set should be the maximal element of the lattice. In other cases results are stated a little haphazardly, as for example Theorem 4.9 on p. 25 where in (i) the author means to say that the chain $a=a_0 \geqq a_1 \geqq a_2 \geqq \cdots$ is ultimately constant. The only genuine error which the reviewer found was Theorem 5.7 on p. 84 for which a counter example exists. This situation requires that Corollary 6.5 on p. 88 be proved directly, which is quite easily done. Other minor errors are mentioned in the Isbell review.

Despite some minor imperfections which can easily be rectified in future editions, this book is an important addition to mathematical literature and should be placed in every college and university mathematics library.

BARRON BRAINERD, University of Toronto

Harmonic Analysis. 1965 MAA Cooperative Summer Seminar. By Lynn H. Loomis, notes by Ethan Bolker. Mathematical Association of America, Buffalo, 1966. 350 pp. (paper) $3.00. (Teleg. Review January 1967)

As the author states in his preface, "The principal theme of these notes is the development of the heavy machinery required to manipulate the Fourier transform." The first half of the book presents basic theorems of linear functional analysis and harmonic analysis on a locally compact abelian group. In the second half attention is restricted to harmonic analysis on euclidean n-space where weak methods are applied, via the Fourier transform, to prove some theorems about linear partial differential equations.

Because of insufficient complementary results and exercises (only eight) which would deepen understanding of the principal theorems, these notes are not recommended as a primary text. The content, enhanced by an informal style, makes the book valuable for general reading. It provides insight into applications of harmonic analysis for the modern analyst and a different approach to linear differential equations for the classical analyst. Supposedly, the only prerequisites are first year graduate level topology, measure theory and algebra. However, since the text is loaded with "big" theorems, some previous knowledge of functional analysis or partial differential equations would make its reading more enjoyable and worthwhile.

RICHARD ILTIS, University of Toronto

Introduction to Computing. By T. E. Hull. Prentice-Hall, Englewood Cliffs, N. J., 1966. xi+212 pp. $7.75. (Teleg. Review March 1967)

In discussing the development of computers, one usually talks in terms of generations.

First generation computers contained tubes, second generation computers utilized solid state devices, and the current question is whether the third generation has been reached. Can introductory textbooks on computing be classified in the same way? The first generation would be the programming manuals initially supplied by the organization that manufactured the computer; these were usually incomprehensible to the novice. The second generation would be the programming texts designed for the beginner and usually published commercially. The central characteristic of a third generation text, in this classification, is the focus on the computer as a processor of symbols rather than solely as a computer of numerical values. In this sense this book belongs to the third generation.

This book is intended as an introductory text and, according to the author, requires nothing beyond high-school mathematics, except for one example and a few exercises which can be omitted. From a pedagogical viewpoint the book has several desirable characteristics: briefness, numerous exercises, a widely available language (FORTRAN IV) and material on nonnumerical applications. My personal preference is to delay machine language and assembly programming (covered in Chapter 2 and 3) as long as possible in an introductory course. The book appears to be one of the best candidates now available for freshman or sophomore courses.

D. TEICHROEW, Case Institute of Technology

The Logic Design of Transistor Digital Computers. By G. A. Maley and J. Earle. Prentice-Hall, Englewood Cliffs, N. J., 1963. x+322 pp. $12.95.

This book presents an introductory treatment of the logic design techniques used to derive NAND/NOR circuits currently in use in modern digital computers and digital devices. Extensive use is made of Karnaugh map methods for both logic design and minimization. They are applied principally to NAND/NOR combinational logic circuits and asynchronous sequential circuits. The mathematical and theoretical foundations of the subject are developed only in minimal fashion.

Use for a year as a supplemental text in the second semester of a one-year graduate course in the logical design of digital computers at the University of Southern California indicated that the text was too elementary and nonmathematical at this level.

I. S. REED AND C. R. WALLI, University of Southern California

A Survey of Geometry, Vol. II. By Howard Eves, Allyn and Bacon, Boston, 1965. xiii+496 pp. $9.95. (Teleg. Review Feb. 1967)

This volume contains Chapters 9–16 ("the analytical and the more abstract portions of the subject") of a two volume survey of geometry. Volume I was reviewed in this MONTHLY, 72 (1965) 691. All of the excellent features of Volume I (clear exposition, imaginative and extensive problem lists, and extensive use of historical information) are carried over to Volume II.

The topics developed at more than a superficial level include the geometry of complex numbers (Chapter 12), the classical differential geometry of curves and surfaces (Chapter 14), and the combinatorial topology of 2-manifolds (Chapter 15). Shorter treatments of more than just a descriptive nature include solvability and insolvability with Euclidean tools (Section 9.3), geometrical applications of the intermediate value theorem (Section 13.3), and pathological curves and surfaces (Section 13.4). These should not be omitted from the "basic course" as outlined by the author.

The major pedagogical difficulty of this text, but one of its great virtues as a reference, is the large number of definitions which appear in rapid succession for the student to learn. For example, under "curve(s)" there are over 100 entries in the index (including lituus, orthoptic, and orthotomic).

In the preface to Volume I and again in its review the question is raised as to whether

the author will do for geometry what Birkhoff and MacLane did for modern algebra in 1941. This reviewer's opinion is that he has not and that in order to do this a survey of geometry, especially one that claims to present the analytical and more abstract portions of geometry, must exploit linear algebra to present a more extensive and rigorous treatment of n-dimensional affine and projective spaces.

This text is excellent for a terminal course in geometry for prospective teachers. Although it is not appropriate as the basic text for a class of good mathematics majors preparing for graduate study, it is valuable as a source of supplementary reading assignments for such a class.

P. B. YALE, Pomona College

About Vectors. By Banesh Hoffmann. Prentice-Hall, Englewood Cliffs, N. J., 1966. ix+134 pp. (paper) $3.75.

The enormous proliferation of college mathematics textbooks, most of which are uninspired, unoriginal and dull, makes it especially pleasing to pick up an unpretentious paperback like "About Vectors" and find that it does have ideas, genuine originality and a flavor that will give delight to students and instructors alike. Instead of presenting a neat linear path through the subject of vectors, the author raises all sorts of questions which he hopes will "disturb and annoy." The provocative questions and roadblocks strewn in the path of the reader exhibit a wealth of experience in teaching the subject and thoughtful reflection upon the difficulties involved—and there seem to be very serious difficulties. For example, early in the game one is faced with the question: What is a vector? Is it any quantity with length and direction? or a directed segment? or an equivalence class? or an undefined algebraic entity? The spirit of raising such questions continues, giving the reader insights into the subject, *per se*, and to the peculiar ways in which it is applied (in physics). Of particular interest is the chapter on Vector Products and Quotients of Vectors. The embarrassing character of the cross-product is not kept secret; that it is a pseudovector rather than a vector paves the way for an introduction of quarternions and a subsequent chapter on tensors. There is also a very nice discussion relating cross-products to oriented areas and boundaries. This discussion will give students valuable assistance in understanding the integral theorems of Stokes and Gauss. Unfortunately, the chapter on tensors is too bare to provide the same sort of service as its predecessors.

No vector calculus appears. This is a mixed blessing, for it makes the book accessible to a large audience but precludes its use as the text for a standard vector analysis course. The principal use for "About Vectors" will probably be as an auxiliary text for any course (including physics courses) in which the subject of vectors plays a central role. However, its use in any manner is sure to give ultimate pleasure in spite of—or because of—the author's design to "disturb and annoy."

SEYMOUR SCHUSTER, University of Minnesota

Modern Algebra, vols. I and II. By Seth Warner. Prentice-Hall, Englewood Cliffs, N. J., 1965. viii+797 pp. vol. I, $12.95; vol. II, $11.95.

These volumes are intended primarily as a text, at the junior-senior level, in a two-semester introductory course in abstract algebra. By omitting appropriate portions, they can be used for students who have been introduced to linear algebra earlier in the undergraduate curriculum. The amount of space devoted to linear algebra is large; the text contains nearly all topics covered in such a text as Hoffman and Kunze's *Linear Algebra*.

There are six chapters in the first volume, five in the second. The chapter headings give a good idea of the diversity of topics. They are: I Algebraic Structures; II New

Structures from Old; III The Natural Numbers; IV Rings and Fields; V Vector Spaces; VI Polynomials; VII The Real and Complex Number Fields; VIII Algebraic Extensions of Fields; IX Linear Operators; X Inner Product Spaces; XI The Axiom of Choice. As the author points out, there is too much material in the two volumes to be covered in one year, so the instructor has freedom in choosing topics to cover. Although the author states that there are sufficiently many topics in the first volume for a year course, most people teaching such a course would want to include topics from both volumes.

The writing is lucid and, as the author hopes, the student ought to be able to read it easily, thus leaving class time for problems. There are occasions, however, when the notation becomes cumbersome. Also, there are places where use of the author's notation would waste a student's time; for example, see the definition of automorphism group of E over k, p. 527. References to earlier portions of the text are not always made easy for the reader. For example, exercise 35.21, p. 392, refers to (N), whereas there is no hint in the exercise as to where (N) can be found; actually, it is on p. 380. The text contains a reasonable number of illustrative examples and many good exercises. The exercises come in all degrees of difficulty, with hints for the more difficult ones. Many exercises are attributed to this MONTHLY. There is no bibliography, which seems a mistake. The index is unusually full, containing references not only to the text but to the exercises.

It might have been better for the author to have had a chapter on group theory. The material on groups is scattered throughout the text. The concept of a group is introduced at the end of the first chapter, while such an elementary result as Lagrange's theorem appears, on p. 293, in the last section of the chapter on Rings and Fields.

In summary, the volumes have many good features, which will make them very useful in the presentation of a first course in abstract algebra. Of the large number of algebra books which have appeared recently these may be included among the better written ones.

ALICE T. SCHAFER, Wellesley College

Numbers and Ideals. By Abraham Robinson. Holden-Day, San Francisco, 1965. 106 pp $5.95.

As the tremendous bulk of twentieth century mathematics continues to grow, so does the danger that the student will miss much of its beauty by being exposed to the latest abstractions and generalizations before he has much knowledge of the specific mathematical objects or theories that are being abstracted or generalized. Thus a student may become thoroughly adept with categories, functors and commutative diagrams but still know little of the theory of groups, rings and modules. Similarly an extensive course in theory of groups or rings sometimes leaves a student with little knowledge of specific groups or rings.

Professor Robinson's book has been written primarily to combat this type of mathematical training. In an elementary and readable style he has written the story of unique factorization in the ring of integers, its failure in rings of algebraic integers of certain quadratic fields and of its restoration in the form of unique factorization for ideals. This is a beautiful chapter of mathematics, in which much of abstract ideal theory has its roots, but which is often neglected in modern courses in abstract algebra. The exposition is kept as simple as possible by treating only quadratic fields. The book should prove a valuable addition to the growing mathematical literature addressed to able undergraduates. Some exercises are provided to test the reader's understanding. There are several typographical errors that should be corrected in a second printing. (*Editorial Note:* Since this review was written, a second edition has been printed with corrections and added problems.)

D. C. MURDOCH, The University of British Columbia

Elements of General Topology. By Sze-Tsen Hu. Holden-Day Series in Mathematics, 1964. 214 pp. $8.95.

The author whose interests in mathematics are extensive and varied (a book on algebra and one on homotopy theory have been published recently with rumours of more to come) shows his usual pedagogical skill in this text also. He writes with a clear style and adheres to a high standard of mathematical rigor. Supplying basic information first, the author begins with a treatment of the standard elements of general topology, emphasizing basic concepts and properties. The proofs are presented in a concise manner and carefully chosen examples keyed to the main line of development are given.

While textbooks in general topology proliferate as never before, there is something new presented in this text. The last three chapters (pages 111 to 200) deal with more specific topics which have not previously appeared in books or have appeared only in advanced treatises. Chapter IV discusses cellular polytopes. Chapters V and VI deal with function spaces and fundamental groups. These chapters should be of interest to all mathematicians. A bibliography of 46 books and 17 research papers as well as a list of special symbols and abbreviations concludes the book. The text contains many exercises of varying degrees of difficulty. According to the author, it is designed as a text for an introductory first course in general topology for advanced undergraduates and beginning graduate students. In the reviewer's opinion, the text might offer some difficulties to the average beginning graduate student, but it would be ideal for the mathematically more mature one.

DAGMAR HENNEY, The George Washington University

Complex Variable Methods in Science and Technology. By John Cunningham. Van Nostrand, Princeton, N. J., 1965. viii+178 pp. $7.50.

This textbook is primarily a compendium of techniques involving complex methods, purportedly designed to furnish the prospective scientist and engineer with the necessary tools for successful pursuit of their fields. Such a book might have been welcome a generation or so ago; today, however, there are several excellent books which meet the present-day needs of the scientifically oriented student far more adequately and admirably, thereby making the present book not too desirable.

I am certain that the style of presentation will be unnerving not only to mathematicians but to scientists as well. Theorems are not always precisely stated; proofs are often slip-shod or are completely omitted, even though the necessary background is available. Important concepts such as bounded function, region, curve, simple curve, boundary points, multiple points are not defined. Some concepts such as line integral and analytic function are not well defined. Such expressions as "continuity" has something to do with "smoothness" and "the shape of this function" jar the nervous system. My experience has shown that most students taking courses in mathematics insist on precision and clarity of expression.

For a book that is addressed to engineers and scientists, it is woefully lacking in substantial applications. The phrase " . . . plays an important role in many two-dimensional problems in classical electrostatics, electric current flow, and non-viscous hydrodynamics" is of typical occurrence. However, since the terminology of the applied fields is not defined, the sprinkling of the text with this jargon hardly enhances its effectiveness as a text in applied mathematics.

Even as a "methods book," it has some serious shortcomings. For example, a consideration of well-known general theorems in the residue theory (well within the grasp of the student at this level) would obviate the necessity of establishing certain results in every problem that is encountered.

The chapter headings are: Real Variable Theory; Complex Numbers, Analyticity;

Conformal Transformations; Integration; Improper Integrals; Many-valued Functions; Beta, Gamma and Delta Functions; Differential Equations. At the end of each chapter is a set of exercises, mostly standard; some are culled from British university examination papers—even these are not exceptionally challenging.

A. E. DANESE, State University of New York at Buffalo

Trends in Elementary School Mathematics. By Lloyd Scott. Rand McNally, Chicago, 1966. ix+215 pp. $3.50 (paper).

Among the readers of the *Monthly* who did not look past the review title there probably is a large number of mathematicians who should read this book. In particular, those who teach mathematics (content) courses for elementary teachers could use the book's map of the contemporary situation and obtain a perspective of the changes taking place in elementary school mathematics curricula. Some of these changes are subtle, some are dramatic; some depend upon pressures from mathematicians, some show the influence of learning theorists. Each of the most important trends is carefully delineated, along with an indication of the conflicts that have arisen recently. Within the various elementary school mathematics projects there are examples of mathematical writing which reflect attitudes and approaches with which most mathematics professors and elementary school teachers are unfamiliar. Consequently, there is a great value in the author's comprehensive survey of major projects and their distinguishing characteristics. This is the basis for the recommendation to *Monthly* readers.

The central section, which discusses mathematical content, is not meant to be sophisticated and it isn't. Consequently, this section will meet with a mixed reception from mathematicians. Nevertheless, they should find the book useful because of the strong points already mentioned, as well as for the later chapters dealing with materials, teaching strategies, and evaluation, plus a set of carefully selected references.

Would that this book were written with an incisive polemic style! Then perhaps mathematicians would react to it, and encourage each other to read it. As it stands, it is a noncontroversial, carefully done survey that should be read by those who have broad responsibilities in teaching mathematics to either elementary school students or to their teachers.

LEONARD FELDMAN, San Jose State College

The Theory of Numbers. By Neal H. McCoy. Macmillan, New York, 1965. 150 pp. $4.95.

The author wrote this short book as a text for a one-semester course at the undergraduate level. There are five chapters. The first deals with divisors and prime numbers. The second and third involve the properties of congruences, polynomial congruences and primitive roots. The fourth deals essentially with the law of quadratic reciprocity and the fifth treats continued fractions. There are some remarks addressed to a reader familiar with some abstract algebra but these may be omitted without affecting the understanding of the subsequent material.

I find the book somewhat meager for a regular undergraduate course. I see no reason why, in considering $f(x) \equiv 0 \bmod p^k$, the author limited himself to the case where $f(x) \equiv 0 \bmod p$ and $f'(x) \equiv 0 \bmod p$ have no solution in common. Quadratic reciprocity is never utilized to get any significant results. There is no general discussion of number theoretic functions, and diophantine equations are limited essentially to the linear congruence. There are not enough challenging problems for the better students.

In my opinion this would be an excellent text in number theory in a good many summer institutes. Professor McCoy knows that writing out a proof in a fairly elementary textbook requires a different style from the one used in writing a paper for a mathematical journal. This is the strong point of the book—the unusual clarity of its writing.

SOLOMON HURWITZ, City College, City University of New York

Uniform Spaces. By J. R. Isbell. Mathematical Surveys No. 12. American Mathematical Society, Providence, Rhode Island, 1964. xi+175 pp. $7.50.

This is the first book since Weil's (1937) to be entirely devoted to the subject of uniform spaces. The theory has grown greatly, in large part thanks to the author, and the book will be warmly welcomed. It starts at the beginning and is self-contained, carefully organized and well motivated. Nevertheless it is not easy reading. The statements and proofs of theorems are laconic; the reader must often amplify the details, contending with unfamiliar ideas and terms. (Luckily, there is a good index.) He will be rewarded for his trouble by meeting many striking new results and problems, and gaining new insights into many familiar ones, here generalized from topological to uniform spaces with an increase of significance.

The book begins with a foreword on categories (in the sense of Eilenberg-MacLane rather than of Baire or Lusternik-Schnirelmann). Category theory as such is not used, but categorical notions supply motivation, organization and terminology. After two chapters on fundamentals there come chapters on spaces of functions, polyhedra, compactifications, dimension and "locally fine" spaces (those for which every uniformly locally uniform covering is uniform). There is an extensive bibliography. Each chapter includes problems, many of them important results in their own right, which comment on or complete the results in the text; and it ends with notes giving references to the literature. Some unsolved research problems are stated. The author adds comments from time to time, which the reviewer found always interesting, sometimes baffling, sometimes highly illuminating. (This review has been abridged with the author's permission.—K.O.M.)

A. H. STONE, University of Rochester

Fortran IV. Programming and Computing. By James T. Golden. Prentice-Hall, Englewood Cliffs, N. J., 1965. 270 pp. $4.50.

This book is written as a college-level introduction to computing and programming. The first concern of the author, who is scientific marketing manager of IBM, is with programming rather than specific applications.

As each feature of Fortran is described, the need for it is discussed and examples are given which depict usage. The treatment of Fortran is comprehensive. Two important aspects of Fortran, often ignored by programming manuals, are given detailed attention. Program planning and program testing or "debugging" are discussed in detail and with precision. The importance of these phases is often overlooked by the beginning programmer.

Considered as a whole, this book will be useful not only to the reader who may wish to use it for self-study but also to those who desire to learn more about recently developed features of Fortran.

DAGMAR HENNEY, George Washington University

Functions of a Complex Variable. Tutorial Text No. 2. By D. S. Mitrinovic. P. Noordhoff Ltd., Groningen, The Netherlands, 1965. 114 pp. $4.90.

This book consists of 286 problems in the theory of functions of a complex variable. In the author's words, the problems were "collected over many years with the aim of providing students and teachers with material, the search for which would otherwise occupy much valuable time." Complete solutions are given for some of the problems and answers or hints are given for others, but many problems are left unsolved. The existing solutions present methods that apply to subsequent problems so the situation is not as calamitous as it sounds, although students would probably appreciate more answers.

The topics treated are classical in nature, emphasis being placed on the geometry of

the complex numbers and the elementary analytic functions. Integration theory is omitted as well as topics such as local properties of analytic functions, mapping theorems, and topological properties of families of analytic functions. There is only one short section concerning residues (defined via Laurent series), but a future volume in the Tutorial Text series will be devoted entirely to the calculus of residues.

D. R. SHERBERT, University of Illinois

Matrix Mechanics. By H. S. Green. P. Noordhoff Ltd., Groningen, The Netherlands, 1965. 118 pages. $5.50.

Although the title of this book is "Matrix Mechanics," the emphasis is the application of an operator method to the solution of a number of quantum-mechanical problems, e.g., the simple harmonic oscillator, the particle in a box, and the hydrogen atom (relativistic and nonrelativistic). The only matrices displayed are those associated with the harmonic oscillator, with the angular momentum operators, the Pauli matrices, and the α_j and β matrices in Dirac's theory of the electron.

The book should be available to students who have had a first year course in quantum mechanics and an introductory course on matrix algebra. The author carefully lays the mathematical foundations as they are required in the text, which is supplemented by numerous well chosen exercises. There is a short section on quantum mechanical paradoxes. This and other features should make the book of interest to more experienced readers also.

ERNEST IKENBERRY, Auburn University

Topological Analysis. By Gordon T. Whyburn. Rev. ed. Princeton University Press, Princeton, N. J., 1964. 125 pp. $5.00.

Topological analysis deals with certain basic results of analysis, particularly complex function theory, that are fundamentally topological in nature and can be developed largely by topological methods. In the book under review, the author concentrates on those results from complex function theory which can be obtained with the use of the topological index and openness of mappings.

The first four chapters present preliminary material. Basic set-theoretic topology, in the setting of metric spaces, is given in Chapters 1 and 2. Chapter 3 treats plane topology, providing a topological background for later developments. These three chapters are concise and represent considerable condensation of Chapters 1, 2, and 6 of the author's *Analytic Topology* (American Mathematical Society Colloquium Publications, vol. 28). Chapter 4 is an elementary review of properties of the complex number system.

In Chapter 5, the topological (or circulation) index is introduced and studied. The index is closely related to the winding number of a mapping, and is defined using exponential representations of mappings from a metric space X to the complex plane. Properties of the topological index are applied in Chapter 6, in which a number of standard results of complex function theory are established. These include continuity of the derivative, existence of second and higher derivatives as consequences of differentiability, the maximum modulus theorem, Cauchy's inequality, and series representation. These results are established by topological methods. The author gives, in an appendix, a simplified treatment of the topological index sufficient to yield the results of Chapter 6. Various other results of complex function theory are established in Chapter 7, including Rouché's theorem, and theorems of Hurwitz and Vitali.

The last two chapters concern local and global analysis of open and light open mappings. The main results concern such mappings on 2-manifolds, and are established with the aid of an analysis of the action of such mappings on closed 2-cells. Among the major

results are the theorem of Stoïlow that any light open map from a 2-manifold without boundary to the complex plane is topologically equivalent to an analytic function, and a necessary and sufficient condition that a 2-manifold without boundary be a Riemann surface.

In this revised edition of *Topological Analysis*, the study of differentiability properties of mappings has been simplified. The book is well organized and clearly written. It will, no doubt, stimulate further developments in an interesting and important area of topology, one to which the author has made numerous significant contributions.

STEVE ARMENTROUT, University of Iowa

TELEGRAPHIC REVIEWS

The following abbreviations indicate suggested uses: T (textbook), S (supplementary student reading), P (professional reading for the teacher), TT (teacher training), L (library purchase) 15 (junior level)—18 (second graduate year).

Algebra

The Modified Algorithm of Jacobi-Perron. By Leon Bernstein. Memoirs of the American Mathematical Society, Number 67. Amer. Math. Soc., Providence, R. I. 1966. 44 pp. $1.40 (paper). A generalization of the Euclidean algorithm that yields solutions of algebraic equations. P, L.

Proceedings of the Conference on Categorical Algebra, La Jolla, 1965. Edited by S. Eilenberg, D. K. Harrison, S. MacLane, H. Röhrl. Springer-Verlag, New York, 1966. 562 pp. $14.50. Twenty-two papers which the editors hope give "a representative, if incomplete, coverage of the present activities . . . trend of research . . . in this country." P.

Categories of Fractions and Homotopy Theory. By P. Gabriel and M. Zisman. Springer-Verlag, New York, 1967. x+168 pp. $9.50. Intended as a possible introduction to algebraic topology for "beginners," the algebraist, and "the topologist eager to assimilate the category language." This book appears to presuppose familiarity with homology theory, category theory, and other matters that give a special meaning to "beginners." P.

Sequences, Vol. I. By H. Halberstam and K. F. Roth. Oxford, New York, 1966. xx+290 pp. $10.10. The first of two volumes concerned with "a substantial branch of number theory of which no connected account appears to exist . . . , " the arithmetical properties of particular integer sequences (such as the nature of the distribution of the sequence of primes among congruence classes). Reviewed in *Science* 27 January 1967. P, L.

Finite and Infinite Primes for Rings and Fields. By D. K. Harrison. Memoirs of the American Mathematical Society, Number 68. Amer. Math. Soc., Providence, R. I. 1966. 62 pp. $1.50. If the unusually clear and informative introductory paragraphs are typical, this memoir should be good reading for anyone familiar with "the basic rudiments of ring theory." P, L.

An Introduction to Nonassociative Algebras. By Richard D. Schafer, Academic Press, New York, 1966. x+166 pp. $7.95. Assumes linear and elementary abstract algebra. Bibliography. S (17–18), P, L.

Analysis

Lectures on Quasiconformal Mappings. By Lars V. Ahlfors; manuscript prepared with the

assistance of Clifford J. Earle, Jr., Van Nostrand, New York, 1966. 146 pp. $2.75 (paper). Based on notes for lectures given in 1964, this is the first English treatment of the subject. S (18), P.

Distributions and the Boundary Values of Analytic Functions. By Edward J. Beltrami and M. R. Wohlers. Academic Press, New York, 1966. xiv+116 pp. $6.50. A research monograph assuming abstract analysis and addressed to "applied mathematicians, theoretical physicists, research engineers, advanced graduate students." P.

Perturbation Theory for Linear Operators. By Tosio Kato. Springer-Verlag, New York, 1966. xix+592 pp. $19.80. "Perturbation theory for linear operators is a collection of diversified results in the spectral theory of linear operators, unified more or less loosely by their common concern with the behavior of spectral properties when the operators undergo a small change." The author assumes only linear algebra and real and complex analysis. Functional analysis is developed as needed. Very brief history and a bibliography. T (17), P, L.

Mixed Boundary Value Problems in Potential Theory. By Ian N. Sneddon. North-Holland, Amsterdam, 1966. vii+283 pp. $12.75 (through Wiley in U. S. and Canada). A survey of recent work with brief historical remarks and a short bibliography. P.

Computer Science

Advances in Computers. Edited by Franz L. Alt and Morris Rubinoff. Academic Press, New York, 1966. xiii+303 pp. $14.00. Highly parallel information processing systems, programming language processors, the man-machine combination for computer-assisted copy editing, computer-aided type-setting, programming language for computational linguistics, computer driven displays and their use in man-machine interactions. P, L.

Computer Programming and Related Mathematics. By Richard V. Andree. Wiley, New York, 1967. 284 pp. $6.50. "This book is prepared in the belief that you can learn to program a modern computer and that in today's world every educated person must have at least a rudimentary knowledge of how computers work." Computer languages, GOTRAN, programming logic, FORTRAN, computer-related mathematics, 1620 machine language, and symbolic programming via elementary exposition, "over a thousand small computer problems and myriad noncomputer problems as well as a set of a more difficult type of 'term project' long problems." The book was tried in two preliminary editions. T (first undergraduate course), S, P, L.

Numerical Inversion of the Laplace Transform. Applications to Biology, Economics, Engineering, and Physics. By Richard Bellman, Robert E. Kalaba and Jo Ann Lockett. American Elsevier, New York, 1966. vii+249 pp. $9.50. Fourth in the series *Modern Analytic and Computational Methods in Science and Mathematics* based on the thesis "that the modern computer has become so powerful that it requires reformulation of many classical processes . . ." P, L.

Control Systems Functions and Programming Approaches. Volume A: Theory. Volume B: Applications. By Dimitris N. Chorafas. Academic Press, New York, 1966. xxvi+395 pp. $16.00. xx+276 pp. $11.00. The author, a Parisian management consultant in the computer field, studied industrial control systems in both the U. S. and Europe as a basis for this book whose main purpose is "to discuss and explain in a fundamental manner some of the control systems functions which became important in industrial practice during very recent years." "Fundamental" refers to the inclusion of "guidance logic" and "mathematical understructure." P, L.

Functional Analysis and Numerical Mathematics. By Lothar Collatz. Translated by Hansjorg Oser. Academic Press, New York, 1966. xx+473 pp. $18.50. Mainly concerned with those parts of functional analysis which relate to numerical applications, "does not claim to be a textbook of either functional analysis or numerical analysis" but rather an account of changes in the latter due to computers and abstract analysis. S (17–18).

An Introduction to Algorithmic Methods Using the MAD language. By Alan B. Marcovitz and Earl J. Schweppe. Macmillan, New York, 1966. ix+433 pp. $6.95. ". . . Using a computer does not eliminate the need for careful work in the solution of problems; in fact, it places a premium on such work and adds some new aspects. In addition to the careful logical and mathematical analysis of problems, one must now consider the following: the structure of the available input data and the desired results; the structure and efficiency of the computational algorithm which describes the process of getting from the input to the results; the linguistic means of expressing this algorithm to the computer; the capacity and weakness of computers; the problems involved in debugging and running the algorithm on a computer; and finally, the careful verification of the results to assure that they are meaningful . . . " We may ask Alfred E. Neuman to comment on the MAD language (Michigan Algorithm Decorder). T (13–14), S, P.

Solution of Equations and Systems of Equations. By A. M. Ostrowski. Academic Press, New York, 1966. xiv+338 pp. $11.95. Numerical analysis of solving equations. This edition is "thoroughly revised" and is nearly double the size of the first edition which was favorably reviewed in *Mathematical Reviews* when it appeared in 1960. S, P, L.

Mathematical Methods for Digital Computers, Vol. 2. Edited by Anthony Ralston and Herbert S. Wilf. Wiley, New York, 1967. x+287 pp. $11.95. A sequel to volume 1 containing 13 papers under the topics of programming languages (Fortran and Algol), quotient-difference algorithm, numerical linear algebra, numerical quadrature, numerical solution of equations, random number generation, and rational Chebyshev approximation. P, L.

Information. A Scientific American Book. Freeman, San Francisco, 1966. 218 pp. $5.00 (cloth), $2.50 (paper). Twelve essays on the present and future of "information machines" (computers), touching on such topics as logic and memory, system analysis, time sharing, transmission of data, information storage and retrieval, artificial intelligence, applications in science, technology, organizations and education. S.

Education

Mappings of the Plane. With applications to trigonometry and complex numbers. By H. E. Chrestenson. Freeman, San Francisco, 1966. vi+171 pp. $2.50. Written for and used for several years in summer and inservice institutes for high school teachers. TT, S (Linear Algebra), P.

Contemporary mathematics for elementary teachers. By Howard F. Fehr and Thomas J. Hill. Heath, Boston, 1966. xii+394 pp. $7.95. "All the material is presented from the contemporary mathematical viewpoint as exemplified in the writings of SMSG and CUPM." TT (Pre- and in-service).

Major Topics in Modern Mathematics. Set and Group Theory By D. E. Mansfield and M. Bruckheimer, with a foreword by W. H. Cockcroft. Harcourt, Brace & World, New York, 1965. 252 pp. $6.50. This is a "working text for teachers," designed for inservicing reading by high school teachers but possibly suitable also for teacher training. TT.

Introduction to Modern Mathematics for Elementary Teachers. By Dora McFarland and Eunice M. Lewis. Heath, Boston, 1966. x+406 pp. $7.50. "The material used in this textbook grew out of conferences held by the CUPM and the broad teaching experience of the authors." TT (pre- and in-service).

History

Bibliography of Schlicht Functions. By S. D. Bernardi. New York University, 1966. ix +157 pp. Free from the Courant Institute, 251 Mercer Street, New York, N. Y. A superb bibliography of 1694 titles arranged alphabetically by author and followed by a partial index by periodical, a list of expository papers, and a subject index of 68 topics. Let there be more bibliographies like this! With them we might hope for more reading and less writing, more awareness of previous work and less duplication, and perhaps even higher standards of scholarship in mathematics! L.

Kūshyār Ibn Labbān, "Principles of Hindu Reckoning." A translation with introduction and notes by Martin Levey and Marvin Petruck of the Kitāb fī usūl hisāb al-hind. Univ. of Wisconsin Press, Madison, 1965. 114 pp. $6.00. Facsimile text, translation, extended commentary (41 pp.) and glossary. Perhaps the oldest surviving Arabic text using Hindu numerals, it contains material supporting the claim that the Arabs were more than mere transmitters. P, L.

The Selected Papers of E. S. Pearson. Issued by the Biometrika Trustees to celebrate his 30 years as editor. Univ. of California Press, Berkeley, 1966. vi+327 pp. $6.75. Twenty-one papers selected from 112 listed in a bibliography. Joint papers with J. Neyman will be published separately. P, L.

Studien zur Mathematik des John Wallis, (1616–1703). Winkelteilungen, Kombinationslehre und zahlentheoretische Probleme. By Christoph J. Scriba. Steiner, Wiesbaden, 1966. 144 pp. DM. 32. A scholarly analysis, based on books and unpublished manuscripts of the mathematical and educational role of Wallis. P, L.

Essays in Mathematical Economics. In honor of Oskar Morgenstern. Edited by Martin Shubik. Princeton Univ. Press, 1967. xx+475 pp. $12.50. Following a too-brief essay on Morgenstern's contributions and a bibliography of his works, appear twenty-seven papers on game theory, programming, decision, economic theory, management science, international trade, and econometrics. P, L.

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor J. C. Eaves, University of Kentucky, represented the Association at the inauguration of President K. K. Wilson of Asbury College on March 28, 1967.

Professor J. C. Lanz, Harrisburg Area Community College, represented the Association at the Centennial Convocation at Lebanon Valley College on April 8, 1967.

Professor R. C. Meacham, Florida Presbyterian College, represented the Association at the inauguration of President J. V. Elmendorf of New College on February 22, 1967.

Professor Henry Sharp, Emory University, represented the Association at the Centennial Convocation at Morehouse College on February 18, 1967.

Professor R. F. Shortt, Keuka College, represented the Association at the inauguration of President G. W. Glick of Keuka College on April 15, 1967.

Professor R. W. Veatch, University of Tulsa, represented the Association at the inauguration of President G. O. Roberts and the Dedication Services of Oral Roberts University on April 2, 1967.

Professor Dale Woods, Northeast Missouri State Teachers College, represented the Association at the inauguration of President J. C. Weaver of the University of Missouri on April 18, 1967.

Abilene Christian College: Assistant Professor S. E. McReynolds has been promoted to Associate Professor; Associate Professor J. C. Bradford has been promoted to Professor and Head of the Mathematics Department.

Colorado School of Mines: Dr. A. J. Boes, Purdue University, has been appointed Assistant Professor; Mr. D. L. Bohmont, University of Wisconsin, has been appointed Assistant Professor; Associate Professor D. C. B. Marsh has been promoted to Professor.

East Tennessee State University: Mr. T. H. Jablonski, Jr., Castle Heights Military Academy, has been appointed Assistant Professor; Mr. G. G. Killough, Jr., University of Tennessee, has been appointed Assistant Professor; Dr. J. C. Pleasant, East Carolina College, has been appointed Associate Professor.

Florida State University: Dr. W. A. LaBach, Northwestern University, has been appointed Assistant Professor; Associate Professor H. C. Griffith has been promoted to Professor.

Fort Hays Kansas State College: Mr. Robert Gumm has been promoted to Assistant Professor; Assistant Professor Ellen C. Veed has been promoted to Associate Professor.

Marquette University: Dr. P. R. Bender, University of Iowa, has been appointed Assistant Professor; Associate Professor E. W. Swokowski has been promoted to Professor.

University of Minnesota: Associate Professors Alfred Aeppli and D. A. Storvick have been promoted to Professors.

University of Missouri at Rolla: Associate Professors C. E. Antle and S. J. Pagano have been promoted to Professors; Professor J. R. Foote, University of New Mexico, has been appointed Professor; Dr. A. J. Penico, Stanford Research Institute, has been appointed Professor; Dr. A. G. Haddock, Arkansas College, has been appointed Associate Professor.

Texas Woman's University: Mr. R. V. McPherson, University of Texas, has been appointed Assistant Professor; Assistant Professor B. L. Fincher has been named Acting Chairman of the Department of Mathematics.

Assistant Professor W. P. Cooke, West Texas State University, has been promoted to Associate Professor.

Assistant Professor A. L. Deal, III, Virginia Military Institute, has been promoted to Associate Professor.

Mr. W. H. Drake, Upper Iowa College, has been promoted to Assistant Professor.

Mr. J. E. Garner, Lambuth College, has been appointed Assistant Professor at Greensboro College.

Associate Professor S. P. Hoffman, Jr., Trinity College, has been appointed Professor and Chairman of the Department of Mathematics at State University College at Cortland.

Associate Professor Lloyd Montzingo, Seattle Pacific College, has been promoted to Professor.

Mr. C. O. Worm, Adams State College, has been promoted to Assistant Professor.

Professor J. A. Beane, SUNY at Buffalo, died on March 5, 1967. He was a member of the Association for thirteen years.

Professor Margaret R. Davis, Southeastern Louisiana College, died on January 5, 1967. She was a member of the Association for twenty-four years.

Professor A. G. Hill, North Dakota State University, died in January 1967. He was a member of the Association for nineteen years.

Professor L. A. MacColl, Polytechnic Institute of Brooklyn, died on January 20, 1967. He was a member of the Association for thirty-four years.

Professor Emeritus W. M. Miller, Dickinson College, died on September 23, 1966. He was a member of the Association for thirty-nine years.

Professor J. P. Russell, Polytechnic Institute of Brooklyn, died on April 15, 1967. He was a member of the Association for seventeen years.

GEOMETRY IN SECONDARY SCHOOLS—AN NCTM PUBLICATION

This 64-page booklet is a report of the joint meeting of the Association and the NCTM which was held at Houston on January 28, 1967. It is available for 50 cents from the National Council of Teachers of Mathematics, 1201 Sixteenth Street, N.W., Washington, D. C. 20036.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

NEW SECTIONAL GOVERNORS OF THE ASSOCIATION

The following have been elected Governors of the Association for the three year term July 1, 1967 to June 30, 1970, by a mail vote of the Association in the Sections indicated:

Kansas	R. N. Bradt, University of Kansas
Missouri	Paul Burcham, University of Missouri at Columbia
New Jersey	Joshua Barlaz, Rutgers—The State University
Northeastern	Miss Grace Bates, Mount Holyoke College
Ohio	H. M. MacNeille, Case Western Reserve University
Pacific Northwest	Joseph Hashisaki, Western Washington State College
Southeastern	R. W. Ball, Auburn University
Southwestern	A. P. Hillman, University of New Mexico
Upper New York State	F. D. Parker, St. Lawrence University

The highest percentage of voters was 46% in the Kansas Section, followed by the Missouri Section with 43%.

RAOUL HAILPERN, *Associate Secretary*

MARCH MEETING OF THE MICHIGAN SECTION

The annual meeting of the Michigan Section of the Mathematical Association of America was held on Saturday, March 18, at the University of Michigan, Ann Arbor, in

conjunction with the meeting of the Michigan Academy of Arts and Letters. Professor James Powell of Western Michigan University presided at the sessions. A total of 123 persons attended the meeting.

At the business meeting, the following officers were elected: Professor Beauregard Stubblefield, Oakland University, Chairman; Professor E. A. Nordhaus, Michigan State University, Vice-Chairman; Professor Lester Serier, Central Michigan University, Secretary-Treasurer.

Professor Lyle Mehlenbacher reported on the activity of the Board of Governors and announced that funds were available for section projects.

Professor W. E. Deskins gave a report on the tenth annual Michigan Prize Competition stating that 26,000 High School students took part in the contest.

Professor Phillip Jones pointed out that financial support for the High School Visiting Lecturers program is being discontinued by the National Science Foundation; it was decided that a committee be appointed to take steps to reinstate the program with Michigan Council support.

The following program was presented:

1. *Geometries of the Erlanger program*, by I. E. Vance, Michigan State University.

2. *The use of the telephone in the teaching of elementary college mathematics*, by Beauregard Stubblefield, Oakland University.

3. *Regular-faced polyhedra with holes*, by B. M. Stewart and N. W. Johnson, Michigan State University.

4. *The decimal expansion of log n*, by J. S. White, General Motors Research Laboratory, Warren.

5. *The domesticated integral test*, by George Piranian, University of Michigan.

6. *Functions of a matrix*, by J. S. Frame, Michigan State University.

7. Panel discussion.

L. H. SERIER, *Secretary-Treasurer*

APRIL MEETING OF THE MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA SECTION

The 1967 Spring Meeting of the Maryland-District of Columbia-Virginia Section of the MAA was held at the University of Virginia, Charlottesville, Virginia, on Saturday, April 22, 1967. Chairman T. L. Reynolds presided. Total attendance was 127.

During the morning session, four papers were presented:

1. *Green's Matrix for a Linear Difference System*, by A. L. Deal, Virginia Military Institute, Lexington, Virginia.

Green's matrix is obtained for the difference analog of a linear differential system. The differential Green's matrix is shown to be the limit, in a certain sense, of the difference Green's matrix.

2. *On the Brown method of fictitious play for two-person zero sum games*, by Stephen Jauregui, Jr., Bethesda, Maryland.

Two-person zero sum games can be solved by a variety of methods, the common methods being graphical, matrix, linear programming and the Brown approximation method. The Brown method of fictitious play is investigated for two factors; speed of obtaining a solution and the ability to extract more than one solution, in case multiple solutions exist. The Brown method is found to be quite slow and to give only one solution for a single computer run. A variation on the method which is both faster and often able to produce more than one solution on a single computer run is discussed.

3. *Existence and uniqueness properties of subfunctions of Boolean functions*, by R. E. Schwartz, Institute for Defense Analyses, Arlington, Virginia.

A Boolean function $f(x_1, \cdots, x_n)$ is said to be of order n if it is dependent upon each of the variables $x_1, \cdots, x_n$. A subfunction of lower order is obtained by assigning the value 0 or 1 to one or more of the variables. Two questions arise: (1) Does $f(x_1, \cdots, x_n)$ have at least one subfunction of order r, for every integer r in the range $1 \leqq r < n$? (2) Is $f(x_1, \cdots, x_n)$ uniquely determined by its subfunctions? The first answer is yes. The second answer is also yes, with one curious exception called the "alternating symmetric function."

4. *A very fast integrator for orbital computation*, by E. H. Weiss, IBM Federal Systems Division, Gaithersburg, Maryland.

Professor K. Stumpff of Goettingen has conceived a new method for computing orbits of spacecraft. The method uses several osculating conic sections to approximate the orbit over large spans of time. If desired, numerical integration may be used to improve the solution. The integrator has been programmed in FORTRAN IV and is much faster than methods in current use. Typical cases are examined for accuracy and machine execution times.

The afternoon session was opened with an invited address by Professor A. G. Mackie of the Institute for Fluid Dynamics and Applied Mathematics, University of Maryland, who offered *Some Comments on Existence and Uniqueness Theorems in Applied Mathematics with an Application to Thin Airfoil Theory.*

Following Professor Mackie's address, three papers were presented:

5. *Two point boundary value problems and their application to celestial mechanics*, by R. L. Stallard, IBM Federal Systems Division, Gaithersburg, Maryland.

6. *The geometric configurations associated with the osculating quadrics at a point of an analytic surface*, by P. D. Thomas, Naval Research Laboratory, Washington, D.C.

By considering certain polar reciprocal relations between the osculating quadrics of Darboux and of Bompiani at a given point of an analytic surface, the resulting geometric configuration was studied. Plane loci discovered included conics, cubics, quartics, and sextics. Space loci discovered included twisted cubics, quadric cones, osculating planes, ruled cubic surfaces, tangent developable quartic surfaces, osculating linear complexes and null systems of twisted cubics, a skew involution, and a linear congruence.

7. *New methods of calculating Bessel functions of integral order and complex argument*, by A. S. Elder, Aberdeen, Maryland.

Bessel functions of the first kind, both ordinary and modified, are calculated for an index which is large compared to the argument. The standard recurrence relation is used to obtain functions of lower order. Bessel functions of the second kind are decomposed into (1) a finite series satisfying a nonhomogeneous recurrence relation stable for increasing index, (2) a logarithmic part depending on functions of the first kind, and (3) an infinite series satisfying a nonhomogeneous recurrence relation stable for decreasing index. Results obtained by combining these elements are generally accurate to about 14 significant figures.

A short business meeting followed during which reports were tendered and routine business was conducted. The following officers were elected for one-year terms beginning 1 July, 1967: Chairman: Avron Douglis, University of Maryland; Vice-chairmen: Mary A. Lee, Sweet Briar College, and S. H. Schot, American University; Secretary: S. L. Gulick, University of Maryland; Treasurer: Joseph Milkman, U.S. Naval Academy.

The meeting concluded with the showing of two MAA films, *Theory of limits* (*Part I*), with E. J. McShane and *Let us teach guessing*, with George Polya.

G. N. TRYTTEN, *Secretary*

APRIL MEETING OF THE MISSOURI SECTION

The spring meeting of the Missouri Section of the MAA was held at Northeast Missouri State Teachers College, Kirksville, Missouri, on April 29, 1967, Professor Dale Woods, Chairman of the Section, presiding. Sixty persons were present of whom fifty-one were members.

At the business meeting the following officers were elected for 1967–68: Chairman, Professor Louise Beasley, Lindenwood College; Vice-Chairman, Professor Guido Weiss, Washington University; Secretary-Treasurer, Professor R. J. Mihalek, University of Missouri at St. Louis.

Professor John Andrews of St. Louis University reported on the high school testing program. Professor Paul Burcham of the University of Missouri at Columbia reported on the progress his committee is making in writing the history of the Missouri Section.

During the morning session Professor Neil Foland of Southern Illinois University gave the main address, "Convex Sets."

In addition to Professor Foland's address, three papers were presented during the morning session. The afternoon session consisted of three papers followed by a number of films. The following papers were presented during the two sessions:

1. *Nontopological character of completeness*, by Ralph Jones, University of Missouri at Kansas City.

2. *Geometry and composite functions*, by J. J. Andrews, St. Louis University, St. Louis.

3. *Optimization and elementary calculus*, by J. R. Foote, University of Missouri at Rolla.

4. *Bivariate probability distributions satisfying a certain summability condition*, A. G. Haddock, University of Missouri at Rolla and V. Seshadri, McGill University. (Presented by A. G. Haddock.)

5. *A mathematical model for musical composition*, by H. A. Padberg, R.S.C.J., Maryville College of the Sacred Heart, St. Louis.

6. *A brief biography of Professor George H. Jamison*, by Mary Jane Kohlenberg, Northeast Missouri State Teachers College.

E. C. PRINGLE, *Secretary-Treasurer*

APRIL MEETING OF THE OHIO SECTION

The fifty-first annual meeting of the Ohio Section of the MAA was held at The Ohio State University, Columbus, Ohio, on Saturday, April 22, 1967. Professor David Lipsich, Chairman of the Section, presided at the business meeting and Professors D. H. Staley and B. J. Yozwiak presided at the program sessions. One hundred seventy-five persons registered in attendance including one hundred forty-three members of the Association.

The following officers were elected: Chairman, Professor Daniel Finkbeiner, Kenyon College; Chairman Elect, Professor Arnold Ross, The Ohio State University; Secretary-Treasurer, Professor Foster Brooks, Kent State University; Program Committee: Professor B. J. Yozwiak, Youngstown University, Chairman; Professor R. A. Clark, Case Institute of Technology; Professor David Brown, Hiram College.

Regular reports were made by the Chairman and the Secretary-Treasurer; there were also special reports by Professor C. E. Capel for the Committee on Curriculum (CONCUR) and by Professor J. L. Smith for the Committee on Teacher Training and Certification (CONTTAC).

The following program was presented:

1. *Non-measurable subsets of the unit interval* $[0, 1]$, by Nand Kishore, University of Toledo. Let λ^* be the Lebesgue outer measure on subsets of the real numbers. Let P be a Lebesgue

nonmeasurable subset of $[0, 1]$ such that the difference of any two elements of P is an irrational number. Then it can be shown that if P_r is a translation of P by r modulo one, where r is a rational number in $[0, 1]$, then P_r is non-measurable and that $\lambda^*(P_r) = \lambda^*(P)$. This leads to the following THEOREM: There exists a sequence $(P_n)_{n=1}^{\infty}$ of disjoint, Lebesgue nonmeasurable subsets P_n of $(0, 1]$ such that $[0, 1] = \mathsf{U}_{n=1}^{\infty} P_n$ and $\sum_{n=1}^{\infty} \lambda^*(P_n) = \infty$.

2. *A consequence of the non-existence of certain generalized polygons*, by S. E. Payne, Miami University.

3. *Euclidean completeness—metric versus synthetic*, by J. L. Smith and Joyce Heick, Muskingum College.

Metric and synthetic (Hilbert) formulations of completeness are stated and used in the proofs of theorems to help demonstrate their difference. The particular contribution of this paper is the presentation of Hilbert's completeness theorem which was translated from the 9-th edition of Hilbert's *Grundlagen der Geometrie*. The paper concludes by presenting a set which is synthetically but not metrically complete.

4. *Some results on triangular numbers*, by Syed Asadulla, Miami University.

5. *Affine transformations in a complex three-space interpreted in a real Argand six-space*, by Hunter Hardman, Marshall University.

A method for the representation of complex three-space in a real six-space is first given. Two types of linear four-spaces in the six-space are defined as "regular" and "anti-regular" four-spaces. Eighteen transformations of the complex three-space are given and when interpreted in the real six-space, they transform "anti-regular" four-spaces into "anti-regular" four-spaces. These transformations are all orthogonal in the six-space and each is a direct rotation or a rotation followed by a reflection upon a subspace of the six-space.

6. *Generalized implication and the Russell Paradox*, by J. G. Maxwell, Kent State University.

A relation called *implicative accompaniment* is defined for propositional functions on differing domains. This implicative accompaniment is shown to be a generalization of each of material, formal and strict implication. Some properties of this implicative accompaniment are outlined and the barber version as well as the original version of Russell's so-called paradox is examined and seen to involve a double implication (if and only if) which, because of circumstances now easily identified, must be false and hence not useful in answering the standard question occurring in the statement of the "paradox."

7. *Sufficient conditions for strong differentiation in infinite dimensional space*, by Thyrsa A. Frazier, Central State University.

Several writers have shown that if f is a bounded measurable function on Euclidean m-space, then the indefinite integral of f is strongly differentiable. Examples have been given of bounded measurable functions defined on infinite dimensional torus-space Q_w whose indefinite integrals are not strongly differentiable. In the present paper it is shown that for f in Q_w a sufficient condition for the strong differentiability of the indefinite integral is that f be the limit of a uniformly convergent sequence of bounded measurable functions, each depending on a finite number of the variables.

8. *An underworked example for linear algebra*, by C. A. Long, Bowling Green State University.

Vector spaces whose elements are polynomials over the real field provide illustrative and easy to obtain examples which are useful in the study of linear algebra. Such polynomial space examples lead to questions, conjectures and generalizations which are not so apparent from the usual n-tuple space or geometric space examples.

9. *The area of a Pythagorean triangle*, by I. A. Barnett, Ohio University.

It is well known that the area of a primitive Pythagorean triangle can never be a square or

twice a square. It is shown here that the area of such a triangle cannot be of the form t^p, $2^{p-2}t^p$, or $2^{p-1}t^p$, provided the Fermat conjecture is true for such a p. For example, if $p=5$, the area of a Pythagorean triangle cannot be of the form t^5, $8t^5$ or $16t^5$, and this leaves undecided the forms $2t^5$ and $4t^5$. From these results other consequences are derived on the area of a Pythagorean triangle.

10. *Some new directions for the Ohio Section*, by David Lipsich, Chairman of the Section, (Chairman's address).

11. *Topics in mathematical logic*, by Jan Mycielski, Visiting Professor, Case Institute of Technology, on leave from the Mathematical Institute, Polish Academy of Science in Warsaw (by invitation).

This lecture pointed the role of first order logic in modern mathematics and described a procedure for checking the tautologies of the propositional calculus essentially contained in A. Ehrenfeucht and E. Orlowska, *Mechanical proof procedure for propositional calculus*, Bull. Acad. Polon. Sci., Série Sci. Math. Astr. et Phys., 15 (1967) 25–30.

FOSTER BROOKS, *Secretary-Treasurer*

APRIL MEETING OF THE SOUTHEASTERN SECTION

Florida Presbyterian College was host to the 46th annual meeting of the Southeastern Section of the MAA, March 31–April 1, 1967. Professor C. V. Aucoin, retiring Chairman of the Section, and Professor R. C. Meacham, Chairman of the Mathematics Department of Florida Presbyterian College, presided at the general sessions. Two one-hour invited addresses were scheduled for the general sessions: "A Nonlinear Parabolic Problem," by F. A. Ficken (New York University) and "Functional Equations and Binary Topological Algebras," by A. D. Wallace (University of Miami). The program included a panel discussion: "The mathematics preparation expected of students transferring as juniors from a Junior College to a Senior College." Members of the panel were: H. E. Taylor (Florida State University), Waldemar Olson (University of Florida), William Tessin (Florida Atlantic University), E. P. Miles (Florida State University). Among the contributed papers, two sections were of special interest—one devoted to partially ordered algebraic systems, the other devoted exclusively to presentations by students. A banquet was scheduled Friday evening, and the program which followed it included a talk by Professor G. K. Reid (Department of Biology, Florida Presbyterian College) and two films supplied by Modern Learning Aids: John von Neumann, and Challenge in the Classroom (R. L. Moore).

Total registration for this meeting was 278, including 82 nonmembers of the Association. The following officers were elected: Chairman, R. E. Wheeler (Samford University); Vice-Chairman, Trevor Evans (Emory University). The invitation from East Carolina College to act as host to the 1968 meeting was reaffirmed, and an invitation from Winthrop College, Rock Hill, South Carolina, to act as host to the 1969 meeting was accepted.

Upon the adjournment of the business meeting, members from the state of Florida met to take initial steps in the formation of a Florida Section of the MAA. Professor Howard Taylor discussed the present status of the petition to form a separate Florida Section. Approval of the idea of a separate Section was voted unanimously by those present. Professor Taylor was elected Chairman *pro tem* and a committee was elected to nominate a slate of officers in anticipation of the establishment of this Section.

The following contributed papers were presented:

1. *Concerning metric intervals*, by E. L. Bethel, Clemson University.

Let (X, ρ) denote a metric space. The point c of (X, ρ) is said to be between points a and b

of (X, ρ) iff $\rho(a, c)+\rho(c, b)=\rho(a, b)$. We denote this in brief by acb. $I(a, b)$ denotes a subset of (X, ρ) such that $x \in I(a, b)$ iff $a \times b$. $I(a, b)$ is called an interval.

Let $M \subset I(a, b)$. Then the point $c \in M$ is said to be an extremal point of M iff there is no other point $z \in M$ such that acz or there is no other point $z \in M$ such that zcb.

THEOREM. *If (X, ρ) is complete and M is a closed subset of $I(a, b)$, then M contains an extremal point.*

2. *A new look at an old problem*, by R. G. Blake, University of Florida.

One sometimes sees the problem "Solve x raised to the x power raised to the x power $\cdots=2$ for x." Another way to state the problem is "Find x such that as $n \to \infty$ the limit of $a_n=2$ where $a_1=x$ and $a_{n+1}=x^{a_n}$. This is an example of the problem of finding u where $u=f(u)$ for a given function f.

3. *On doubly autographic groups*, by L. M. Chawla, University of Florida.

A group G is called autographic, if it can be embedded isomorphically into $A(G)$, the group of all automorphisms of G. A group G is defined to be doubly autographic, if both G and $A(G)$ are autographic.

THEOREM I. *(a) A group G having the identity as its centre is doubly autographic. (b) A group G which is a direct product of groups each of which has identity as its centre is doubly autographic. In particular a direct product of nonabelian simple groups is doubly autographic.*

THEOREM II. *(a) If $G=\Pi_{i \in A} H_i$, A an index set, is a direct product of its subgroups H_i, each of which is autographic, then G is autographic. (b) If in $G=\Pi_{i \in A} H_i$, each H_i is doubly autographic and characteristic, then G is doubly autographic. (c) If G be the direct product of its centre C and a subgroup H, then G is doubly autographic if C is doubly autographic and H is characteristic.*

4. *The Krull-Schmidt theorem for loops*, by David Clark, Emory University.

A new proof is given of the uniqueness of direct decomposition for loops satisfying ascending and descending chain conditions on normal subloops. The theorem, of course, is already known, not only for loops, but for more general algebraic systems. The main virtue of this proof is the closeness with which it parallels the standard proof for the group case. A particular point of interest is the development of a substitute for the binomial theorem in a neo-ring.

5. *Products of points—some simple algebras and their identities*, by Trevor Evans, Emory University.

A study is made of the identities satisfied by algebras of ordered pairs of elements of a set S with products defined by $(a, b) \cdot (c, d)=(\ ,\)$ where the product pair is chosen in some fixed manner from a, b, c, d. The product $(a, b) \cdot (c, d)=(b, c)$ satisfies the identity $xy \cdot yz=y$ which has the interesting property that any finite model of it has a square number of elements.

6. *Cyclically vertex-symmetric graphs*, by Forrest Dristy, Robert Ferguson and Alexander Hunter, Florida Presbyterian College.

A vertex-symmetric graph is called cyclically vertex-symmetric (CVS) if its vertices can be numbered (modulo n) in a manner such that one of its automorphisms maps any vertex, having number k, onto the vertex numbered $k1$. This type of graph can be completely described in terms of the vertices incident with the vertex numbered zero. If $t_1, t_2, \cdots, t_d$ are the vertices incident with zero on a graph with n vertices, then a graph with vertices $s_1, s_2, \cdots, s_d$ incident with zero is isomorphic if and only if there is a number relatively prime to n such that $mt_1, \cdots, mt_d\, s_1, \cdots, s_d$. The paper also contains a theorem which gives the index of imprimitivity for a CVS graph.

7. *Some transformations that reduce complex boundaries in every face of a parallelepiped to zero*, by R. M. Fiterre, Alabama University in Huntsville.

8. *The Riesz interpolation property in ordered groups*, by Laszlo Fuchs, University of Miami. (30 minutes)

Let A be an additively written abelian group with a partial order $\leqq$ such that $a \leqq b$ implies $a+c \leqq b+c$, and the elements $\geqq 0$ generate A. The Riesz interpolation property asserts that if both a_1, a_2 are $\leqq$ both b_1, b_2, then some $c \in A$ satisfies $a_i \leqq c \leqq b_j$ for $i, j = 1, 2$. Lattices share this property with $c = \sup(a_1, a_2)$, and there are lots of important groups which are not lattice-ordered and have the Riesz property, e.g., real polynomials or differentiable functions in the unit interval. The simplest types are the antilattices; here $\sup(a_1, a_2)$ exists only when either $a_1 \leqq a_2$ or $a_2 \leqq a_1$. Every A with the Riesz property is a subgroup of a cartesian product of antilattices.

9. *The substitution sign*, by B. A. Fusaro, University of South Florida.

The operation of substitution would seem to warrant a standard notation. Many texts have a list of notations but they fall short of including a notation for substitution. Similarly, mathematics dictionaries do not appear to recognize a special sign. . . . In practice, devices such as parentheses or brackets are used, and the constants to be substituted are written in various places. About a century ago, F. Sarrus introduced a notation to symbolize this operation, and mathematicians conceded the value and utility of having a special sign to indicate substitution. Sarrus' sign was modified by A. Cauchy, and others, and what emerged was a vertical bar written to the left of the function. The "limits" of substitution were placed like the limits of integration. This serviceable notation, only occasionally used today, allows a simplicity and even an elegance in expressing certain relations as, e.g., the fundamental theorem of the calculus and integration-by-parts.

10. *Mathematics by television and graduate student teachers at the University of Florida*, by W. A. Gager, University of Florida.

This paper relates the $3\frac{1}{2}$ years experience of teaching elementary college mathematics by television and using graduate student teaching assistants to conduct the discussion in the small section groups and to give individual aid as needed.

11. *A stability theorem for closed linear operators*, by Leland Graber, Florida Presbyterian College.

Let T and S be linear operators with domains in a Banach space X and ranges in a Banach space Y. Let T be closed with closed range and let S be bounded with respect to T. Suppose that the image of the null space of T under S has only the zero element in common with the range of T. The author introduces a condition which is sufficient to insure that the range of $T+\lambda S$ is closed and the null space of $T+\lambda S$ is fixed for all complex numbers λ in a deleted neighborhood of 0.

12. *On the construction of a ternary quadratic form*, by E. H. Hadlock and Amin Muwafi, University of Florida.

In this paper positive values are given to a, and d, the determinant associated with the form $f = ax^2+by^2+cz^2+2ryz+2xz$. Formulas are obtained by which integral values of b, r and c are obtained in that order. This method of construction is a generalization of the method given by L. E. Dickson.

13. *Maximal starshaped sets*, by W. R. Hare, Jr. and J. W. Kenelly, Clemson University.

While any set S in a linear space has maximal convex subsets, this is not true for starshaped sets in general. However, if S is a compact subset of an n-dimensional linear topological space, there exist maximal starshaped subsets and all such maximal sets are closed.

14. *The use of Cartesian tensors in development of complex equations of motion*, by W. G. Heffron, Bellcomm, Inc.; W. H. Land, Jr., IBM Federal Systems Division.

Part I. The purpose of Part I, and Part II to follow, is to demonstrate the use of Cartesian tensors in the development of equations of motion of particles and rigid bodies. It is shown that Cartesian tensors have many advantageous features; in particular, (a) ω^* (crossproduct) term

arises in a simple manner, (b) development of the inertia tensor is straightforward, and (c) the resulting equations are unambiguous and can be reduced to computable form with relative ease. Part I covers the following: brief review of the vector approach; discussion of pertinent properties of direction cosines; solution of simple rigid body motion by this method; and particle motion about the earth, referred to inertial, geocentric ecliptic, and earth-fixed axes.

Part II. Part II of this presentation reviews the classical tensor approach and concentrates on the application of Cartesian tensors to development of the equations of motion of a helicopter. The development considers the helicopter as a group of rigid bodies constrained to move together in a useful fashion. The forces and torques of constraint are, however, eliminated in the useful versions of the equations.

15. *Rational inequalities—a simplified approach*, by C. W. Huff, Winthrop College.

Let $q(x)=\Pi_{i=1}^{m}(x+p_i)$, $p_1<p_2<\cdots<p_m$, be a polynomial over the reals; so that $x+p_1<x+p_2<\cdots<x+p_m$ for any real number x. Then $\{x:q(x)<0\}$ is found by inspection in preference of the detailed case studies that are usually advocated in undergraduate texts. From this result one can easily ascertain the solution set $\{x:g(x)/h(x)<0\}=\{x:f(x)=g(x)h(x)<0\}$, where $g(x)$ and $h(x)$ are polynomials over the reals.

16. *A property related to absolute pure for modules*, by B. H. Maddox, Florida Presbyterian College.

In this paper, all rings have unity and all modules are unitary. If A is a ring, a left A-module E is said to be *pure with respect to* a right A-module F if for any left A-module H containing E (as a submodule) the canonical map $F\otimes E\to F\otimes H$ is an injection. The paper consists of proving four immediate results from this definition using isomorphisms that exist between certain tensor products.

17. *On oscillatory matrices*, by T. L. Markham, Auburn University.

The definition and basic structure of oscillatory matrices were given by F. R. Gantmacher and M. G. Krein in *Compositio Math.*, v. 4 (1937) 445–476. A canonical representation for an oscillatory matrix is determined, and this form is used to derive upper bounds for the determinant of an oscillatory matrix which improves a bound of Gantmacher-Krein. Special classes of oscillatory matrices are investigated and determinantal bounds are discussed relative to these classes. Finally, if A is an oscillatory matrix, a necessary and sufficient condition for A^{-1} to be an M-matrix is proved.

18. *On a form representing a large collection of primes*, by L. M. Chawla, J. E. Maxfield, and R. G. Selfridge, University of Florida.

Let p be an odd prime. It is determined which odd prime p can be represented by the form $p=|x^l\pm m(x\pm 1)|$ where l and $m\leqq\frac{1}{2}(x-1)$ are positive integers, and x an odd prime, $p\leqq 80,413$. It is determined that less than 3% of the primes in the range considered cannot be represented in this way.

19. *Linear programming a generalized traveling salesman problem*, by J. G. May, Wake Forest College.

Given n cities, in what order should they be visited so that no city is encountered twice and the distance traveled is a minimum?

We assume the existence of n points in m-dim. space such that the "Manhattan distance" between points equals the specified distance between corresponding cities.

Using these points, we formulate a linear programming solution to the above problem. The number of constraints is $2n+(n-1)m$ and the number of variables is $n^2+2(n-1)m$. The description easily submits to a generalization of this problem.

20. *On the proximate fixed-point property for multifunctions*, by T. B. Muenzenberger, University of Florida.

A multifunction F on a space X into a metric space Y is ϵ-continuous provided each point x admits a neighborhood U such that $F(x)$ is a subset of $S_\epsilon(F(x'))$ and $F(x')$ is a subset of $S_\epsilon(F(x))$ for each x' in U. A metric space X has the proximate fixed-point property for multifunctions (pFpp) provided for each $\eta>0$ there exists an $\epsilon>0$ such that for every ϵ-continuous multifunction F on X into itself there exists a point x in X such that $d(x, F(x))<\eta$.

THEOREM 1. If a metric space X has the pFpp, then every compact m-retract of X has the pFpp.

THEOREM 2. If a compact metric space X has the pFpp, then every metric homeomorph of X has the pFpp. Theorems 1 and 2 are extensions of theorems of Klee (*Stability of the fixed-point property*, Colloq. Math., 8 (1961) 43–46).

21. *On the equivalence of a ternary quadratic form*, by E. H. Hadlock and Amin Muwafi, University of Florida.

If g and its reciprocal G are two properly primitive, positive or indefinite, ternary quadratic forms, then g is equivalent to a properly primitive form, $f=ax^2+by^2+cz^2+2ryz+2sxz+2txy$ with $(a, s, t)=1$. There exists a linear transformation T of determinant 1 which takes f into an equivalent form, $f_1=a_1x^2+b_1y^2+c_1z^2+2r_1yz+2s_1xz+2t_1xy$ such that $a_1=a$, and $(s_1, t_1)=1$. Finally, every properly primitive, positive or indefinite, ternary quadratic form, with a properly primitive reciprocal, is equivalent to a properly primitive form in which the coefficients of $2xz$ and $2xy$ are one and zero respectively.

22. *The pseudo-join in implicative semilattices, by* W. C. Nemitz, Southwestern at Memphis.

Let $\langle L, \leqq, \wedge, * \rangle$ be an implicative semilattice. If a and b are elements of L, the pseudo-join of a and b is defined to be $((a*b)*b)\wedge((b*a)*a)$. The pseudo-join is an upper bound of a and b, is the larger of a and b if they are ordered, is idempotent, commutative, and absorbtive with respect to meet. Furthermore, the following conditions are all equivalent: (i) that the pseudo-join be a join, (ii) that it be associative, (iii) that it be monotone, (iv) that it satisfy either distributive law with respect to meet, (v) that it satisfy the generalized De Morgan Law.

23. *An application of Abel's identity*, by G. B. Parrish, Army Research Office, Durham, N. C.

One often asks if the solution of a boundary value problem is continuously differentiable in a closed region containing the boundary. Consider the problem: Find a function u which is harmonic in the interior R of a right circular cylinder of unit radius and which vanishes on the boundary of the cylinder except at one end where $u=f(r)$. Here r is the distance from the cylinder's axis and $f\in C''$ $[0, 1]$, $f'(0)=f(1)=0$. Using simple relations, such as Schwarz' inequality and Abel's summation identity, it is shown that the Fourier-Bessel series solution of this problem is continuously differentiable throughout $\overline{R}$.

24. *Some game-theoretic problems*, by L. T. Ratner, Vanderbilt University.

A game-theoretic approach is used in connection with the solution of certain problems arising in deterministic mathematical models.

25. *A semigroup of convex sets*, by Harold Reiter, Clemson University.

It is shown that the class C of compact convex subsets of a real normed linear space X with vector addition, is a commutative semigroup with an identity. C is made into a topological semigroup with continuous real operators. G. K. Sheppard has recently shown that certain classes of convex sets form a Hilbert space.

The operator $S: C'\to C'(C'=\{[A]=\{A+b \mid b\in X\} \mid A\in C\})$ defined by $S([A])=[(A-A)/2]$ is a continuous idempotent. If P is a parallelogram in E_2, $S^{-1}([P])$ is a singleton.

26. *Report on the activities of the Two Year College Panel of the CUPM*, by W. R. Rice, St. Petersburg Junior College.

The charge to the panel is as follows: to establish the minimum levels of course content acceptable for the Associate Degree or for transfer credit; to study computer methods as they relate

to teaching; to determine the level of mathematical training required of two-year college instructors; to investigate the use of programmed materials; to recommend materials for the library; to determine what should be included in the "General Education" mathematics program; to study the mathematics appropriate for technical and occupational training programs; to develop placement criteria; to investigate how CUPM recommendations could be utilized.

This panel is subdivided into three subpanels as follows: 1. Mathematics for university-parallel students; 2. Mathematics for technical and occupational training; 3. General mathematics for terminal students.

27. *Abnormal semantic matrices—a timely state of the art survey*, by E. P. Miles, Jr., Florida State University.

Abnormal semantic matrices, first defined by Miles at a meeting of this Section of the Association over twelve years ago, are subsets of the class of literate matrices, i.e., those with non-numeric alpha-numeric characters as elements, which are optically or phonetically comprehensible in their basic form and remain comprehensible when subjected to one or more of such operations as reflections, inversions, reversions or orthogonal transformations. Additional canonical forms or under-the-counter examples will be displayed which are multiply decomposable, phonetically implausible or punitively ill-conditioned. Applications to psychotherapy and mirror writing will be given.

28. *On the admissibility of a mean on certain continua*, by K. N. Sigmon, University of Florida.

A *mean* on a space is a continuous commutative, idempotent binary operation on the space. A *mean* is called *autodistributive* if $(xy)z=(xz)(yz)$ for all x, y, z in the space. It is not known whether the subspace S of the plane consisting of the set $W=\{(r, s)\,|\,s=\sin(1/r),\ 0<r\leqq 1\}$ together with its limit continuum C admits a mean. Some relevant results follow. Let $D=S\cup\{(r, x)\,|\,(2-r, x)\in S\}$, a subset of the plane.

PROPOSITION 1. If S admits a mean, then $xC=C$ for all $x\in C$.

PROPOSITION 2. S admits no mean which is internal (i.e., $\min\{x, y\}\leqq xy\leqq\max\{xy\}$) on W.

PROPOSITION 3. If S admits an autodistributive mean, then C is an ideal of S (i.e., $SC\subset C$).

PROPOSITION 4. D admits no autodistributive mean.

29. *A permanent inequality*, by P. B. Sigrest, Auburn University.

The following theorem is proved:

Suppose B is an $n\times n$ matrix with root λ and corresponding normalized column characteristic vector $x=(x_1, x_2, \cdots, x_n)$. Then per $(BB^*)\geqq|\lambda|^{2n}\Pi_{i=1}^{n}|x_i|^2 n!$ When B is stochastic, we obtain per $(BB^*)\geqq n!/n^n$. In order for this bound to be significant, λ must be nonzero and x must contain no zero elements. However, this generalizes some of the results obtained by M. Marcus and H. Minc on bounds for permanents of positive semidefinite matrices.

30. *Torsional stresses in a cyclindrically aeolotropic material*, by C. B. Smith, University of Florida.

A mathematical method of investigating the torsional stresses in a cylindrically aeolotropic material is presented. The method is applied to obtain the system of stresses in a hollow cylinder produced by couples acting on the ends. Several types of hollow cylinders are discussed including a cylinder with a varying diameter.

31. *Fully and partially ordered extensions of the real field*, by Andrew Sobczyk, Clemson University.

Any algebra $D(S)$ of real functions on a set S, with order defined by nonnegative functions as nonnegative elements, contains an order-isomorphic copy of the real field R for each scalar-multiple class of such a function $x\in D(S)$. For the continuous function space $C(S)$ of a nonpseudocompact completely regular topological space S, it is known (see, e.g., the book of Gillman and Jerison) that $C(S)/M$ for a nonfixed maximal ideal M is a fully ordered hyper-real field, whose transcendence degree over R is at least the power of the continuum. Theorems are obtained on representa-

tion of a partially ordered commutative algebra as a $D(S)$, as a quotient algebra $D(S)/I$, where I is an ideal of $D(S)$, and on transcendence degrees in the more general situation.

32. *The importance of certain hypotheses in theorems on L-sets*, by A. G. Sparks, Clemson University.

In a paper by Alfred Horn and F. A. Valentine, "Some properties of L-sets in the plane," Duke Math. J. 16 (1949) 131–140, we will refer to two particular theorems. They are:

THEOREM 2.9 *Let S be a simply connected, compact L-set, and suppose each point of S lies in a convex subset of S which is visible from all points of S. Then S is a sum of convex sets every two of which have a point in common.*

THEOREM 2.10 *If S is a simply connected, compact L-set, then S is a sum of convex sets every two of which have a point in common.*

An example was given to show that simple connectedness is needed in Theorem 2.10. This example does not serve for Theorem 2.9 since it does not have the stated visibility property. The following example shows that simple connectedness is needed in Theorem 2.9. Let $P_1=(-2, 2)$, $P_2=(0, 4/3)$, $P_3=(2, 2)$, $P_4=(1, 1)$, $P_5=(1, -1)$, $P_6=(-1, -1)$, and $P_7=(-1, 1)$ be the points with indicated coordinates, and let S be the set $\Delta P_1P_2P_7+\Delta P_2P_3P_4+\Delta P_4P_5P_6+\Delta P_5P_6P_7$. Then S is a compact L-set which is not simply connected, but which does have the desired visibility property. However, S is not a sum of convex sets every two of which have a point in common.

33. *A generalization of the Stone-Weierstrass Theorem to multivalued functions*, by W. T. Spears, University of Florida.

A generalization of the Stone-Weierstrass Theorem is obtained for multivalued functions which gives the classical theorem when the functions are taken as single valued.

34. *On the domain of attraction of the sum of independent random variables*, by C. V. Stanojevic, University of Detroit.

35. *Relations and bigraphs*, by Jagbir Singh and W. A. Thompson, Jr., Florida State University.

This paper generalizes some concepts of directed graphs to configurations which have directed as well as undirected lines. The subject is motivated by paired comparison problems which arise in statistics and by tournaments in which ties may occur. Both direct and indirect comparisons are employed to determine a partial ordering of the players. Conditions are determined under which such an order will exist and the uniqueness question is treated. If no such ordering exists then one may determine a "nearest adjoining order" by deleting and changing the orientation of a minimum number of lines.

36. *The number of solutions of certain systems of equations in a finite field*, R. G. Van Meter, Florida Presbyterian College.

HENRY SHARP, JR., *Secretary-Treasurer*

APRIL MEETING OF THE TEXAS SECTION

The annual spring meeting of the Texas Section of the MAA was held on the campus of Austin College, Sherman, Texas, on April 14–15, 1967. There were 279 persons registered including 176 members of the Association.

Papers were presented Friday in two concurrent sessions chaired by Professors A. D. Stewart of Prairie View A & M, D. H. Martin of Grayson College, T. G. Newman of Southern Methodist University, and B. B. Williams of the University of Texas at Arlington.

The welcoming address was given by President J. D. Moseley of Austin College at a dinner meeting on April 14, 1967 which was presided over by Professor Dale Maness of Austin College.

The general session on Saturday, April 15, 1967 was chaired by Professor C. J. Pipes

of Southern Methodist University and included reports of all committees and of the secretary-treasurer. At this session the following officers were elected for the coming year: Chairman, Dale Maness of Austin College; Vice-Chairman, H. A. Luther of Texas A & M University; Secretary-Treasurer, B. T. Goldbeck, Jr., of Texas Christian University.

The invited speakers for the meeting were Professor E. E. Moise, Harvard University, who spoke on "How to Tell That a Simple Over-hand Knot is Really Knotted" and Dr. T. A. Atchison, Ling-Temco-Vought, who spoke on "Nonlinear Transformations Related to the Evaluation of Improper Integrals."

The following papers were presented:

1. *Periodic solutions of linear difference equations*, by Louis Brand, University of Houston.

The linear difference equation $P(E)\times(t)=f(t)$, in which $P(E)$ is a polynomial of degree n in $E=1+\Delta$ and $f(t)$ is a sequence of period p, has the operational form $P(r)X(r)=Q(r)+F(r)$ (this MONTHLY, 71 (1964) 719–728) where $r=1/s$, the inverse of the shift operator $\{0, 1, 0, 0, \cdots\}$. It has a unique solution $g(t)$ of period p iff the zeros r_j of $P(r)$ are not poles of $F(r)$. If r_j is of multiplicity m_j, the initial values of $g(t)$ are uniquely determined by the n equations $Q^{(i)}(r_j)+F^{(i)}(r_j)=0$, $i=0, 1, \cdots, m_j-1$. Sequences $g(t)$ and $f(t)$ satisfy $P(1)\sum_{t=0}^{p-1} g(t)=\sum_{t=0}^{p-1} f(t)$.

2. *On the weight of a metric space*, by J. C. Bradford, Abilene Christian College.

Since the cardinal numbers are well ordered, there is in every topological space a dense set of smallest cardinal. This is the *weight* of the space. It is shown that in a metric space, there is always an isolated set of largest cardinal and that this cardinal is the weight of the space. Thus the weight has the dual characterization as the largest cardinal of an isolated set and the smallest cardinal of a dense set.

3. *Metrizability conditions in a Moore space*, by Geraldine Fuller Daunis, Texas Christian University and University of Texas at Arlington.

A Moore space is a space satisfying axiom 0 and parts 1, 2, and 3 of axiom 1 of Moore's *Foundations of Point Set Theory*. A Moore space is not necessarily metrizable but whether or not a normal Moore space is metrizable is still unanswered. A normal Moore space which is not metrizable will be completely normal, perfectly normal, and countably paracompact but not paracompact nor pseudo-metrizable.

The author compares a Moore space to some other generalizations of metrizable spaces. Some metrizability conditions are the results. Some of these are conditions that can be put on the basis that they are similar to the equivalent conditions for paracompactness.

4. *Breadth, connectedness, modularity*, by D. E. Edmondson, University of Texas at Austin.

Let L be a topological lattice; the theorem is proved that if L is connected and has breadth less than or equal to two, then L is modular.

5. *Schauder decompositions of some product spaces*, by Jean B. Richmond, Southern Methodist University.

A Schauder decomposition which is both shrinking and boundedly complete is given for the product space $X=\pi_2 X_i$ of a sequence $\{X_i\}_1^\infty$ of nontrivial Banach spaces with respect to l_2. Then X is reflexive if and only if each X_i is reflexive. If each X_i is a certain quasi-reflexive space, then X is isometric with X^{**} but X is not quasi-reflexive. For another choice of the X_i's, X is not isomorphic to any conjugate space.

6. *Restriction of zeros of polynomials to sectors of the complex plane*, by Ruth Goodman, Texas A & M University.

It is possible to write an nth degree polynomial $f(z)$ as a sum of $n+1-k$ definitely defined polynomials $f_{k,j}(n)$ of degree $k<n$. If a sector S contains all zeros of $f(z)$, it is easily shown that S also contains those of all the $f_{k,j}(z)$ and that S is "best possible." The converse problem is more difficult: For given k, let S contain all the zeros of the $f_{k,j}(z)$; determine the minimal sector $S'=S'(S, n, k)$ which must also contain those of $f(z)$. These questions are discussed. Some results are proved, and some problems which remain unsolved are pointed out.

7. *Some set properties of relative extreme points*, by W. J. Matthews, Southwest Texas State College.

For subsets A and S of a linear space L, a point p of S is an extreme point of S relative to A if p is not contained in the relative interior of any line segment having one end point in A and the other end point in S. The purpose of this paper is to present some set properties of relative extreme points.

8. *Some properties of generalized Orlicz spaces*, by Richard O'Neil, Rice University.

9. *On a generalization of separability, the Lindelof property and countable compactness*, by Margaret R. Wiscamb, University of St. Thomas.

A topological space satisfies the discrete countable chain condition (DCCC) if every discrete collection of open sets is countable. This property is a generalization of separability, the Lindelof property and of countable compactness. A regular space satisfies the DCCC if and only if every locally finite collection of open sets is countable. A T_4 space is countably compact if and only if every discrete collection of open subsets is finite.

10. *Fourier series and convolution*, by A. F. Kleiner, Jr., Texas A. & M University.

If f satisfies a countable number of "suitable" conditions then f is the convolution $g*h$ of functions g and h where g is in $L(0, 2\pi)$, even, positive and continuous on $(0, \pi)$ and h satisfies the same conditions that f does. Specifically, the conditions (1) $f \in L(0, 2\pi)$ and $S[f]$ converges to f on a countable set E and (2) f is in $Lp(0, 2\pi)$ for $1 \leqq p < \infty$, are shown to be suitable.

11. *Doctoral programs in mathematics and education as related to instructional needs of junior colleges and four year colleges*, by Wingo Hamilton, University of Texas at Arlington.

The problem of this study was to analyze doctoral programs in mathematics and education designed for the preparation of teachers of undergraduate mathematics. Data were secured, through use of questionnaires, from samples of officials of junior colleges, senior colleges, graduate schools, and from a panel of authorities in mathematics education. Based on these data and a review of the literature, tentative conclusions were drawn as to: (1) the need for such programs, (2) the attitude of college and university officials toward them, (3) the composition of present offerings, and (4) recommendations as to the future course of their development.

12. *Extensions of topologies*, by C. D. Tabor, Texas Christian University and Texas Woman's University.

Let $(X, \mathfrak{I})$ denote a topological space where $\mathfrak{I}$ is some topology on a set X. Norman Levine's definition of a simple extension of $\mathfrak{I}$ by a subset A of S, denoted $\mathfrak{I}(A)$, is given, and relationships concerned with $\mathfrak{I}$-boundary points and $\mathfrak{I}(A)$-boundary points of a subset of X are discussed. A concept of (simultaneously) extending $\mathfrak{I}$ by an arbitrary number of subsets of X is introduced, and a necessary and sufficient condition for an extension of this type to be the simple extension of $\mathfrak{I}$ by the union of the subsets is given. Some theorems concerned with the idea of extending one topology by the members of an open basis for another topology are mentioned.

13. *Mapping induced topologies and everywhere disconnected spaces*, by M. G. Monzingo, Southern Methodist University.

A topology can be induced on a set by a map either to or from a given topological space. In the following, the basic ingredients have been reduced from a set, a map, and a topological space to two sets and a map. Two topologies will be induced by a given map, and a number of results will be obtained. The notion of an everywhere disconnected space will be introduced, and these spaces will be shown to be mapping induced topological spaces.

14. *On convolution and moduli of continuity*, by Jack Bryant, Texas A and M University.

For convolution $f=g*h$ of functions g, h in $L_1[0, 2\pi)$, one usually obtains $w(f, t) \leqq Aw(h, t)$, where w is a "modulus of continuity" $w(f, t)=\sup \{\|f(\cdot+h)-f(\cdot)\| : 0 \leqq |h| \leqq t\}$ with respect to

some Banach space B, $\|\cdot\|$. Under very general conditions on B, one finds this result is best possible in the following sense: if $w(f, t) = 0(w(t))$ then $f = g * h$ where $g \in L$ and $w(h; t) = 0(w(t))$.

15. *Symbols of parabolic singular integrals*, by Max Jodeit, Jr., Rice University.

A certain class of parabolic singular integral operators is characterized in terms of symbols (which reduce to Fourier transforms for operators of convolution type).

16. *Some remarks on the pointwise convergence of singular integrals with nonhomogeneous kernels*, by C. C. Tu, Rice University.

Pointwise convergence of some singular integrals with nonhomogeneous kernels can be established without using J. Peetre's general theorem.

17. *A multi-ordered iteration process for solution of nonlinear simultaneous equations*, by A. R. Crawley and H. A. Luther, Texas A and M University.

An extension of the Newton-Raphson method for the solution of a nonlinear system of equations is presented in a form such that by varying certain parameters the iterative process can take on all orders of convergence up through four. To assure convergence it is required that the initial approximation be close enough to the solution desired, the Jacobian of the system exist at this solution point, and the system has continuous fourth order partial derivatives in a neighborhood of this solution point. The scheme employs derivatives through order three rather than extra function evaluations and thus is appropriate only when derivatives are easily found.

18. *Matrix powers as solutions of a difference equation*, by Louis Brand, University of Houston.

The minimum equation (order m) of an $n \times n$ matrix A can be regarded as a difference equation whose characteristic roots are the eigenvalues λ_i of A. When all $\lambda_i \neq 0$, its solution gives all integral powers A^x in terms of m matrices C_i determined by $A^0 = I, A, \cdots, A^{m-1}$. If all λ_i are distinct, $m = n$, $A^x = \sum_{i=1}^{n} C_i \lambda_i^x$ and $C_i^2 = C_i$, $C_i C_j = 0$ $(i \neq j)$. When A is singular and $\lambda_n = 0$ is simple, $A^{x+1} = \sum_{i=1}^{n-1} C_i \lambda_i^x$; then the set of *singular* matrices A^x form an Abelian group with $A^0 (\neq I)$ as unit and $A^x A^{-x} = A^0$; now $C_i^2 = \lambda_i C_i$, $C_i C_j = 0$ $(i \neq j)$ and A^{-x} is the "inverse" of A^x relative to A^0.

19. *n-Abelian varieties of groups*, by J. R. Durbin, University of Texas at Austin.

The problem discussed is that of generalizing the well-known fact that a group is Abelian if it satisfies the identity $(xy)^n = x^n y^n$ for three consecutive integers n. This leads naturally to questions about certain reduced free groups and to a problem in number theory.

20. *Pseudo involutary linear transformations*, by Shannon Smyrl, Texas Technological College.

A linear transformation A on a vector space V over an algebraically closed field is called pseudo-involutary of order n if and only if $A^n = P$, where P is a fixed projection on the range of A and n is the least positive integer for which $A^n = P$. It can be shown that a linear transformation A on V is pseudo-involutary of order n if and only if $A = m_1 P_1 + \cdots + m_k P_k$, where m_i, $i = 1, \cdots, k$ is an nth root of unity and P_i, $i = 1, \cdots, k$ is a projection such that $P_i P_j = 0$, $i \neq j$, and $P_1 + \cdots + P_k = P$, a projection on the range of A. If $P = I$ then A will be a linear involution.

21. *A note on numerical differentiation*, by S. A. Sims, Texas A and M University, and Sallie Nelson, Lockheed Electronics Company.

From a prescribed discrete sampling of a differentiable function an approximate best fit, in the sense of least squares, to its derivative is obtained.

22. *Junior college mathematics—objectives and curriculum revision—as viewed by a junior college teacher*, by F. L. Ermis, Jr., Wharton County Junior College.

Objectives in mathematics education as related to the general objectives in junior college education and curriculum revision are viewed from a junior college teacher's standpoint. Recommendations are made, along with an appeal for the Texas Section to start a special session at the yearly meeting for junior college teachers.

BEN T. GOLDBECK, JR., *Secretary-Treasurer*

ANNOUNCEMENT OF L. R. FORD AWARDS

At its meeting on January 27, 1965, in Denver, Colorado, the Board of Governors authorized a number of awards, to be named after Lester R. Ford, Sr., to authors of expository articles published in the MONTHLY and the MATHEMATICS MAGAZINE. A maximum of six awards will be made annually; each award is in the amount of $100. The articles are to be selected by a subcommittee of the Committee on Publications appointed for this purpose.

The 1967 recipients of these awards, selected by a committee consisting of R. P. Boas, Chairman; C. W. Curtis, and R. P. Dilworth, were announced by President Moise at the Business Meeting of the Association on August 29, 1967, at the University of Toronto. The recipients of the Ford Awards for articles published in 1966 were the following:

Wai-Kai Chen, Boolean Matrices and Switching Nets, MATH. MAG., 39 (1966), 1–8.

D. R. Fulkerson, Flow Networks and Combinatorial Operations Research, MONTHLY, 73 (1966), 115–138.

Mark Kac, Can One Hear the Shape of a Drum?, MONTHLY, 73 (1966), Part II (Slaught Paper No. 11), 1–23.

M. Z. Nashed, Some Remarks on Variations and Differentials, MONTHLY, 73 (1966), Part II (Slaught Paper No. 11), 63–76.

P. B. Yale, Automorphisms of the Complex Numbers, MATH. MAG., 39 (1966), 135–141.

HENRY L. ALDER, *Secretary*

THE 1967 WILLIAM LOWELL PUTNAM MATHEMATICAL COMPETITION

The twenty-eighth annual William Lowell Putnam Mathematical Competition will be held on Saturday, December 2, 1967. This competition, which is supported by the William Lowell Putnam Intercollegiate Memorial Fund, is under the sponsorship of the Mathematical Association of America. Colleges and universities in the United States and Canada are eligible to register undergraduates in the competition.

Application blanks will be mailed about October 1 to the mathematics department chairmen of the schools on the regular mailing list and also to those who supervised the competition in 1966. If an application blank is not received by October 15, one may be secured by writing the director, James H. McKay, Department of Mathematics, Oakland University, Rochester, Michigan 48063. Your application should be filed with the director not later than November 3, 1967. Further details are provided in the Announcement Brochure which is mailed with the registration forms.

Reports of the previous competitions and the examination questions may be found in the MONTHLY for May 1938, 1939, 1940, 1941, 1942; October 1946; August-September 1947; December 1948; August–September 1949, 1950, 1951; October 1952, 1953, 1954, 1955; January 1957; August–September (announcement of winners) and November (questions and solutions) 1957; August–September 1958, 1959; January (questions and solutions for the eighteenth, nineteenth, and twentieth competitions) 1961; August–September 1961; October 1962; August–September 1963; June–July 1964; August–September 1965, 1966, and in this issue page 771.

QUALIFICATIONS FOR A COLLEGE FACULTY IN MATHEMATICS

In December, 1965, Professor William L. Duren, Jr., then chairman of CUPM, appointed an *ad hoc* committee to prepare a report identifying suitable qualifications for a college faculty in mathematics. Although some members of this committee, including its chairman, were at the time members of CUPM, several were drawn from the ranks of mathematicians and teachers outside CUPM:

L. J. Paige (Chairman), University of California, Los Angeles
A. A. Albert, University of Chicago
R. C. Buck, University of Wisconsin
Bernard Friedman (deceased), University of California, Berkeley
M. G. Humphreys, Randolph-Macon Woman's College
K. O. May, University of Toronto
C. E. Rickart, Yale University
A. B. Willcox, Amherst College
Leo Zippin, City University of New York

Upon succeeding Professor Duren as chairman of CUPM, Professor R. D. Anderson of Louisiana State University became an *ex officio* member of the committee.

At its meeting on January 23, 1967, CUPM approved for publication the committee's report, *Qualifications for a College Faculty in Mathematics*. Taking note of the continuing critical shortage of Ph.D. mathematicians, the report identifies four important components in the formal education of college teachers:

(1) a strong undergraduate mathematics major;
(2) a "first graduate component" which introduces the student to serious graduate work in the principal disciplines of mathematics;
(3) an "advanced graduate component" which includes advanced graduate work and research seminars; and
(4) the doctoral dissertation.

It then describes teaching duties suitable for individuals with academic attainment equivalent to that represented by a given component, and it makes suggestions concerning the composition of a small undergraduate department. The committee believes that, in addition to aptitude for mathematics and interest in teaching, a good college teacher must possess both the willingness and the ability to continue his own education in mathematics indefinitely. The report suggests several activities besides publication which indicate that a teacher is continuing his mathematical growth, and it calls upon college administrations to provide the environment and the opportunity for college teachers to engage in such activities.

CUPM hopes the report will be of interest to college mathematics teachers, to department chairmen and other college administrative officials, to boards of education, and to graduate departments of mathematics at universities offering doctoral programs.

Copies of the report may be obtained without charge by writing to CUPM, Box 1024, Berkeley, California 94701.

PROFESSIONAL OPPORTUNITIES IN MATHEMATICS: NEW EDITION

A new edition of *Professional Opportunities in Mathematics* was published by the Association in September 1967, the seventh edition of this popular booklet. Including the present edition, over 85,000 copies of *Professional Opportunities* have been printed. Annual sales average about 5000 copies.

Professional Opportunities appeared originally in the MONTHLY for January 1951 as the report of a committee of the Association. Successive editions have been revised and rewritten in order to keep the material up to date. The current edition has been prepared by the MAA Committee on Advisement and Personnel, consisting of A. B. Willcox, Chairman, K. J. Arnold, E. A. Davis, J. S. Frame, Mrs. F. J. MacWilliams, C. R. Phelps, and W. H. Schmidt.

CALENDAR OF FUTURE MEETINGS

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

Forty-ninth Summer Meeting, University of Wisconsin, Madison, Wisconsin, August 26–28, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, Indiana University of Pennsylvania, Indiana, April 27, 1968.

FLORIDA

ILLINOIS, Southern Illinois University, Edwardsville Campus, May 10–11, 1968.

INDIANA, Marian College, Indianapolis, November 11, 1967.

IOWA, Wartburg College, Waverly, April 19, 1968.

KANSAS, Marymount College, Salina, Spring 1968.

KENTUCKY, University of Kentucky, Lexington, Spring 1968.

LOUISIANA-MISSISSIPPI, Broadwater Beach Hotel, Biloxi, Mississippi, February 16–17, 1968.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA, Morgan State College, Baltimore, December 9, 1967.

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA, South Dakota State University, Brookings, November 11, 1967.

MISSOURI

NEBRASKA, Nebraska Center for Continuing Education, Lincoln, April 26–27, 1968.

NEW JERSEY, St. Peter's College, Jersey City, November 4, 1967.

NORTHEASTERN

NORTHERN CALIFORNIA

OHIO

OKLAHOMA-ARKANSAS, Federal Aviation Agency, Oklahoma City, March 29–30, 1968.

PACIFIC NORTHWEST, Reed College, Portland, Oregon, June 14–15, 1968.

PHILADELPHIA, University of Delaware, Newark, November 18, 1967.

ROCKY MOUNTAIN, University of Denver, Colorado, May 1968.

SOUTHEASTERN, East Carolina College, Greenville, North Carolina, March 29–30, 1968.

SOUTHERN CALIFORNIA, Loyola University of Los Angeles, Los Angeles, March 9, 1968.

SOUTHWESTERN, New Mexico State University, University Park, Spring 1968.

TEXAS, Texas A and M University, College Station, April 19–20, 1968.

UPPER NEW YORK STATE, State University College at Buffalo, November 4, 1967.

WISCONSIN, Wisconsin State University, La Crosse, May 4, 1968.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, New York, December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, San Francisco, January 23–27, 1968.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, University of California, Los Angeles, June 17–20, 1968.

ASSOCIATION FOR COMPUTING MACHINERY, New York Hilton Hotel, November 10, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC, Sheraton-Boston Hotel, December 27–28, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Hall, Philadelphia, Pennsylvania, April 17–20, 1968.

OPERATIONS RESEARCH SOCIETY OF AMERICA, Sheraton-Chicago Hotel, November 1–3, 1967.

PI MU EPSILON

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, University of California at Santa Barbara, November 29–30, December 1–2, 1967. (Symposium on combinatorial mathematics.)

W. A. BENJAMIN, INC.

recently appointed exclusive world-wide distributor...

Publications Mathematiques

Institut des Hautes Etudes Scientifiques, Paris

Publications Mathématiques has for many years been highly regarded as a distinguished and selective publication of the most significant work of eminent mathematicians with important contributions to make to mathematical knowledge.

Publications Mathématiques will be published several times a year in clothbound volumes averaging 300 pages each. Regular distribution begins with Volume 32, the first issue of 1967. It will contain the fourth part of Alexandre Grothendieck's basic treatise, *Eléments de géométrie algébrique,* entitled "Etude locale des schémas et des morphismes de schémas."

Future volumes will include articles by such well-known mathematicians as Boardman, Segal, Grauert, Milnor, Bass, Cerf, Bruhart, Tits, Krehl, Mostow, and others.

Publications Mathématiques may be obtained only from Benjamin (outside of France). Standing orders as well as individual volumes are available, and a complete list of back issues may be secured by writing W. A. Benjamin, Inc.

W. A. BENJAMIN, INC.

ONE PARK AVENUE • NEW YORK 10016

Outstanding texts

CALCULUS WITH ANALYTIC GEOMETRY

EDWIN J. PURCELL, *University of Arizona.* Rigorous enough to challenge the best student, this text features an early introduction of set theory and a thorough coverage of vectors in two- and three-dimensional spaces. *843 pp., illus., $11.00*

AN INTRODUCTION TO MATRICES, VECTORS, AND LINEAR PROGRAMMING

HUGH C. CAMPBELL, *Virginia Polytechnic Institute.* This text, designed to teach matrix algebra to students with a limited mathematical background, is particularly useful in terminal courses. *244 pp., illus., $6.50*

ELEMENTARY CONCEPTS OF MODERN MATHEMATICS

FLORA DINKINES, *University of Illinois, Chicago.* Hardbound, 457 pp., illus., $6.50, or in three paperbacks: *Elementary Theory of Sets,* 237 pp., illus., $2.65; *Introduction to Mathematical Logic,* 122 pp., $1.65; and *Abstract Mathematical Systems,* 97 pp., illus., $1.45.

New from Blaisdell

FOUNDATIONS IN MODERN MATHEMATICS

W. Graham May, *Wake Forest College*

The purpose of this first-year, one-semester book is to investigate the concepts of set, relation, and function and also to present a selection of topics in both algebra and trigonometry which will give purpose and value to the mathematics the student has to study as well as to build a solid foundation for future courses—especially calculus. Emphasis is on algebraic structure of number systems and properties of elementary functions. Many "modern" and somewhat sophisticated ideas have been brought down to the computational level and are not left entirely at the level of formal logic.

1967. 322 pages. $7.50

COMBINATORIAL THEORY

Marshall Hall, *California Institute of Technology*

Intended for advanced undergraduate and beginning graduate students, this text covers a branch of discrete mathematics. Prerequisites to this material are linear algebra and probability. Among the topics included are—theory of permutations and combinations, theory of partitions and material relevant to design of experiment, linear programming, and finite geometries.

1967. 310 pages. $9.50

FIRST ORDER MATHEMATICAL LOGIC

Angelo Magaris, *Ohio State University*

Written for advanced undergraduate and beginning graduate students who have had little or no acquaintance with abstract mathematics, this text concentrates on first-order logic, presupposing no particular mathematical background. It includes illustrative examples, detailed proof of theorems, and numerous exercises.

1967. 211 pages. $6.75

PROBLEMS IN GROUP THEORY

John Dixon, *University of New South Wales*

This supplementary text on group theory provides a generous source of challenging problems for advanced undergraduate or graduate students. The problems illustrate methods and techniques used in many branches of group theory and enable the student to become familiar with the applications of the theorems which he is studying. Complete solutions are provided.

1967. 176 pages. $7.50

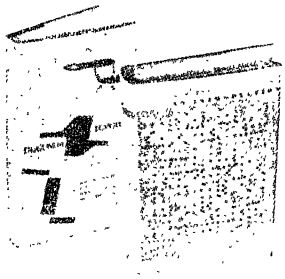
The first two volumes in the Numerical Analysis and Computer Science Series:

STATISTICAL COMPUTATIONS ON A DIGITAL COMPUTER

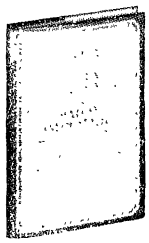
William J. Hemmerle, *University of Rhode Island*

Statistical theory is briefly presented for various applications which are selected because of their importance in applied statistics and numerical analysis. A basic knowledge of computer programming and some advanced calculus and matrix algebra are assumed.

1967. 230 pages. $7.50



NUMERICAL INTEGRATION



Philip J. Davis, *Brown University*
Philip Rabinowitz, *Weizmann Institute, Israel*

Providing a balance between practical computer applications and theoretical topics which underlie numerical integration, this text contains carefully selected material including multiple and automatic integration.

1967. 255 pages. $7.50

The Allyn and Bacon SERIES IN ADVANCED MATHEMATICS

"The Allyn and Bacon Series in Advanced Mathematics is designed to provide expositions of the basic areas of mathematics at the upper undergraduate and beginning graduate levels. It is at this point that the student's acquaintance with modern mathematics really begins. A good text will, of course, supply the usual indispensable features: a high level of exposition, plenty of exercises ranging from routine ones to ingenious challenges, and stimulating glimpses of where the subject goes when you penetrate deeper. A superb text does even more: it lets the student share the excitement that accompanied the great discoveries of the last century. It is to the development of superb texts that the Series is dedicated."

Irving Kaplansky, University of Chicago and Charles DePrima, California Institute of Technology, Consulting Editors

TOPOLOGY

By James Dugundji, University of Southern California

The text presents an introduction to set theory and a comprehensive coverage of general topology. The material is designed for the student with a basic background in differential and integral calculus at the junior, senior, or graduate level. 1966. 447 pp. List $12.95

A SURVEY OF MATRIX THEORY AND MATRIX INEQUALITIES

By Marvin Marcus and Henryk Minc, both of the University of California at Santa Barbara

The text is an invaluable aid to graduate and undergraduate students, as well as a source of reference to working mathematicians who need to know the current state of the field of matrix theory and matrix inequalities. 1964. 180 pp. List $8.95

THE THEORY OF GROUPS: AN INTRODUCTION

By Joseph J. Rotman, University of Illinois

The text is specifically designed for mastery of the fundamentals of group theory by the senior or first year graduate student. The material is unusual in that it contains chapters on simple groups, homological algebra, and word problems. 1965. 305 pp. List $9.95

ALLYN AND BACON, INC., 470 Atlantic Avenue, Boston, Mass. 02210

MODERN COLLEGE ALGEBRA, Second Edition

By ELBRIDGE P. VANCE, *Oberlin College*

This second edition of a highly successful text has included new material on matrices, and a new approach to vectors. Both are strongly recommended at this level and both are perfect preparation for later courses in linear algebra. Also, several references are made to computing machines and methods used in these fields. The problems in this new edition have been augmented and there are four new sets of review problems included at appropriate places. 287 pp., 57 illus. $6.95

ANALYTIC GEOMETRY

By MURRAY H. PROTTER and CHARLES B. MORREY, JR., *University of California at Berkeley.*

This freshman-level text—which may also be used at the high school senior level—is designed for a separate course in analytic geometry to precede the calculus. It can also be used in an integrated course in analytic geometry and calculus, or as a supplement in a straight calculus course.

The book is designed primarily to prepare the student for calculus, and is characterized by logical developments and a normal emphasis on theory. Analytic geometry is developed by coordinates, but vectors are introduced and used. 316 pp., 219 illus. $6.75

CALCULUS FOR COLLEGE STUDENTS

By MURRAY H. PROTTER and CHARLES B. MORREY, JR.

This is a calculus text for students who have had analytic geometry in high school or in a separate college course. Except for the omission of analytic geometry, and the chapter on linear algebra, the content of this text is virtually the same as the authors' *College Calculus with Analytic Geometry.* Like their former book, this text is designed to be equally attractive to students of both science and engineering and pure mathematics. 730 pp., 417 illus. $10.75

MODERN ELEMENTARY DIFFERENTIAL EQUATIONS

By RICHARD BELLMAN, *University of Southern California.*

Emphasizing the formulation of scientific problems, this sophomore-level introductory text was written to give the student a thorough grounding in the theory and application of differential equations. There is particular emphasis upon the formulation of scientific problems in these terms, and applications to biology, economics, engineering and physics are given. The book is intended to provide students, as well as practicing engineers and scientists, with an understanding of the basic methods used to obtain numerical solution of differential equations using both desk and digital computers. In Press.

MATRICES AND LINEAR TRANSFORMATIONS

By CHARLES G. CULLEN, *University of Pittsburgh.*

The first five chapters of this book on linear algebra comprise a one-term text for science engineering and mathematics students which covers those topics most frequently encountered in applications. Only a first course in calculus and analytic geometry is required. Aimed at the sophomore-junior level, the text approaches the subject from the matrix theory point of view rather than from the more abstract approach using linear transformations. 227 pp. $8.95

INTRODUCTION TO VECTOR FUNCTIONS

By JAMES A. HUMMEL, *University of Maryland.*

At the sophomore-junior level, this book offers material for a first course after calculus. It provides the mathematics needed for applications, and is intended mainly for engineers and physicists. The book is carefully and clearly written in the modern mathematical style (theorem, proof, etc.).

Coverage includes vector spaces, linear transformations, determinants, matrices, functions of several variables, differentials, integration, an introduction to curves and surfaces, and vector analysis. 372 pp., 36 illus. $9.75

EDITORIAL CORRESPONDENCE should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with det $[a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00 ($8.00 in 1968). For nonmembers the subscription price is $10.00 ($15.00 in 1968).

FUNCTIONAL DEPENDENCE

W. F. NEWNS, The University, Liverpool

1. Introduction. It has been the fashion for some time for textbooks on Advanced Calculus or Analysis to include a section on Functional Dependence, the general idea being as follows. Real-valued functions $f_1, f_2, \cdots, f_m$ of n real variables are functionally dependent if they satisfy a relation of the form $F(f_1(x), f_2(x), \cdots, f_m(x)) = 0$ identically. Assuming the f_i to be continuously differentiable, it is claimed that the functions are dependent if and only if the rank of their Jacobian is everywhere less than m. It is clearly not intended that every sequence of m functions shall be regarded as dependent (by taking F identically zero) but just what *is* intended by the definition is usually obscure. In the proof of 'only if' in the above result, it is usually supposed that F is continuously differentiable and that its partial derivatives nowhere vanish simultaneously. The 'if' statement is usually deduced from the implicit function theorem on the assumption that the Jacobian has constant rank, and appears to be a local result. From what is assumed about F in the proof of 'only if,' and proved about F in the converse result, one can arrive at an appropriate meaning of 'dependence' for this particular theorem. This meaning, however, differs from the definition given by R. C. Buck [2] in one of the few textbooks where the definition is precise. It also differs from the definition used by A. B. Brown [1], on the basis of which he proves a result similar to the textbook result, but without the hypothesis that the Jacobian has constant rank. (In Brown's theorem there was an extra differentiability hypothesis on the f_i, a hypothesis which was later weakened by A. Sard [9].)

In view of this, it seems worth while to attempt an exposition of the subject, starting with an investigation into the relationship between various possible meanings of 'dependence.'

2. Definitions. We first make

DEFINITION 1. *Let X, I be sets, $(Y_\iota)_{\iota\in\mathrm{I}}$ a family of sets, and for each $\iota\in\mathrm{I}$ let $f_\iota\colon X\to Y_\iota$. Let F be a real-valued function with domain $\mathfrak{D}(F)\subset\prod_{\iota\in\mathrm{I}} Y_\iota$. Then we say that the f_ι are F-related iff $F(f(x))=0$ for all $x\in X$, where $f\colon X\to\prod_{\iota\in\mathrm{I}} Y_\iota$ is the function having (f_ι) as components.*

It is implied here that if (f_ι) is F-related then $\mathfrak{D}(F)$ contains the range $\mathfrak{R}(f)$ of f.

To obtain a useful definition of dependent (as F-related for some suitable F) we must not merely exclude the case where F is identically zero: we need something like the other extreme. The obvious other extreme, namely that F has no zeros, is clearly inappropriate. In a topological space, however, a function is identically zero iff its support is empty. We recall the definition.

DEFINITION 2. *Let Y be a topological space and F a real-valued function with domain Y. The support of F is the subset*

$$\text{supp } F = \overline{\{y \in Y: F(y) \neq 0\}}$$

of Y, where the bar denotes closure in Y.

The support of F is the smallest closed set outside which F vanishes identically. The other extreme from supp $F=\varnothing$ is supp $F=\mathfrak{D}(F)$, but since all we require of $\mathfrak{D}(F)$ is that it should contain $\mathfrak{R}(f)$, it is equivalent for our purposes to make the following definition, which specializes essentially to that given by R. C. Buck ([2] p. 226).

DEFINITION 3. *Let X, I be sets, (Y_ι) a family of topological spaces and for each $\iota \in$ I let $f_\iota: X \to Y_\iota$. We say that the f_ι are functionally dependent iff they are F-related by some F such that supp $F \supset \mathfrak{R}(f)$.*

Buck's requirement on F, namely that it should vanish identically on no nonempty open set, is clearly equivalent.

Having ensured by our requirement on F that the relation satisfied by the dependent functions is as nontrivial as possible, it is natural to impose further restrictions on F.

DEFINITION 4. *Let X, I, (Y_ι), (f_ι) be as in Definition 3. Then we say that the f_ι are C^0-dependent iff they are F-related by some continuous F such that* supp $F \supset \mathfrak{R}(f)$.

DEFINITION 5. *Let X be a set, let m be a positive integer and for each integer i $(1 \leqq i \leqq m)$ let f_i be a real-valued function with domain X. Let p denote ∞ or a positive integer. Then the f_i are C^p-dependent iff they are F-related by some F of class C^p such that* supp $F \supset \mathfrak{R}(f)$. *They are analytically dependent iff they are F-related by some analytic F such that* supp $F \supset \mathfrak{R}(f)$.

3. Topological characterizations of dependence.

PROPOSITION 1. *Let X, I, (Y_ι), (f_ι), f be as in Definition 3. Then the f_ι are functionally dependent iff $\mathfrak{R}(f)$ has no interior point (in $Y=\pi Y_\iota$).*

Proof. Suppose the f_ι are functionally dependent and choose F relating them and such that supp $F \supset \mathfrak{R}(f)$. If y_0 were an interior point of $\mathfrak{R}(f)$, then $\mathfrak{R}(f)$ would be a neighborhood of y_0 on which F vanishes, hence not meeting $\{y \in \mathfrak{D}(F): F(y) \neq 0\}$. This would mean $y_0 \notin$ supp F contrary to $y_0 \in \mathfrak{R}(f) \subset$ supp F. We conclude that no such point exists.

Conversely, suppose that $\mathfrak{R}(f)$ has no interior point and take F to be the characteristic function of $Y \setminus \mathfrak{R}(f)$. Then the f_ι are F-related, and the support of F is the closure of $Y \setminus \mathfrak{R}(f)$, whose complement is an open subset of $\mathfrak{R}(f)$, and hence, is empty. Thus supp $F = Y$ and the f_ι are functionally dependent.

PROPOSITION 2. *If the f_ι are C^0-dependent then $\mathfrak{R}(f)$ is nowhere dense in Y.*

Proof. Let F be a continuous function relating the f_ι and satisfying supp $F \supset \mathfrak{R}(f)$. Then F vanishes on $\overline{\mathfrak{R}(f)} \cap \mathfrak{D}(F)$ and *a fortiori* on $U \cap \mathfrak{D}(F)$, where U is

the interior of $\overline{\mathfrak{R}(f)}$: thus $U \cap \text{supp } F = \varnothing$. If U were nonempty, it would meet $\overline{\mathfrak{R}(f)}$ (it is a subset of it) and hence meet $\mathfrak{R}(f)$ contrary to $\mathfrak{R}(f) \subset \text{supp } F$. We conclude that $U = \varnothing$.

A converse of Proposition 2 is not to be expected without some restriction on the topologies of the Y_ι. We prove only an easy result.

PROPOSITION 3. *Suppose that* I *is countable, that each* Y_ι *is metrizable and that* $\mathfrak{R}(f)$ *is nowhere dense in* Y. *Then the components of* f *are* C^0*-dependent.*

Proof. The space Y being metrizable, we choose a metric for it and let $F(y)$ be the distance of y from $\mathfrak{R}(f)$. Then F is continuous and $F(y) = 0$ iff $y \in \overline{\mathfrak{R}(f)}$. Thus the components of f are F-related and since $\overline{\mathfrak{R}(f)}$ has empty interior, supp $F = Y$.

For the case of C^p-dependence, since this implies C^0-dependence we know from Proposition 2 that a nowhere dense range is necessary for C^p-dependence. Conversely:

PROPOSITION 4. *Let* X *be a set,* m *a positive integer and* $f\colon X \to \boldsymbol{R}^m$ *a function whose range is nowhere dense in* $\boldsymbol{R}^m$. *Then the components of* f *are* C^∞*-dependent.*

Proof. For any integers n, k $(1 \leqq k \leqq m)$, the equation $y_k = n$ defines a hyperplane in $\boldsymbol{R}^m$ (y_k denoting the kth coordinate of $y \in \boldsymbol{R}^m$). All such hyperplanes divide $\boldsymbol{R}^m$ into open hypercubes, and we denote by Q_1 the set of all those hypercubes not meeting $\mathfrak{R}(f)$. For any integer $s > 1$, we divide $\boldsymbol{R}^m$ similarly into hypercubes by means of hyperplanes with equations

$$y_k = n2^{-s} (n \in \boldsymbol{Z},\ 1 \leqq k \leqq m),$$

and denote by Q_s the set of those hypercubes which meet neither $\mathfrak{R}(f)$ nor any element of Q_r for $r < s$. For any positive integer s, we put

$$F_s(y) = s^{-s} \exp\left(-(\sin(2^s \pi y_1) \sin(2^s \pi y_2) \cdots \sin(2^s \pi y_m))^{-2}\right)$$

whenever y belongs to some element of Q_s, and $F_s(y) = 0$ for all other y in $\boldsymbol{R}^m$. It can be shown that F_s is of class C^∞, hence so also is $F = \sum_{s=1}^{\infty} F_s$. It is clear that F vanishes on $\mathfrak{R}(f)$, and hence that the components of f are F-related; also, the support of F contains the union of the Q_s, hence also the complement of $\overline{\mathfrak{R}(f)}$, and since $\overline{\mathfrak{R}(f)}$ has empty interior we see that supp $F = \boldsymbol{R}^m$.

REMARK. By a modified construction it is possible to prove: *Given any closed subset* S *of* $\boldsymbol{R}^m$, *there is an* $F\colon \boldsymbol{R}^m \to \boldsymbol{R}$ *of class* C^∞ *such that* $F(y) = 0$ *iff* $y \in S$. See [1] for details.

For the case of m real-valued functions we see that, for any p, C^p-dependence is equivalent to C^0-dependence and to C^∞-dependence. We thus have only three distinct kinds of dependence. (That the first two are distinct can be seen by considering the projection onto the (x, y)-plane of a well-known dense curve on a torus. Defining

$$f\colon \boldsymbol{R} \to \boldsymbol{R}^2 \text{ by } f(t) = e^{it}(2 + \cos(t\sqrt{2})),$$

we can show that $\mathfrak{R}(f)$ has no interior point but is dense in the annulus $\{z \in \mathbf{C}\colon 1 \leqq |z| \leqq 3\}$. For analytic dependence, an extra topological condition on $\mathfrak{R}(f)$ is necessary [1].)

4. Local dependence. We now suppose that X is a topological space. A family (f_ι) is *locally C^0-dependent* iff each point of X has a fundamental system of neighborhoods such that the restrictions of the f_ι to each of the neighborhoods are C^0-dependent. It is clearly enough that each point of X should possess one such neighborhood. Moreover,

PROPOSITION 5. *If Y is metrizable and the components of f are locally C^0-dependent, then for every compact $K \subset X$, the components of $f|_K$ are C^0-dependent.*

Proof. Each point of K has a neighborhood U such that $f|_U$ has C^0-dependent components, hence such that $f[U]$ is nowhere dense in Y (Prop. 2). We can cover K by a finite sequence (U_i) of such U. Thus $f[K]$, as subset of $\bigcup f[U_i]$, is nowhere dense, and consequently (Prop. 3) the components of $f|_K$ are C^0-dependent.

We next show that, at least in the most usual case, this kind of dependence is not yet another kind, but is equivalent to the first kind. The generality is retained mainly to indicate what is involved.

PROPOSITION 6. *Suppose that X is locally compact and σ-compact, that Y is a complete metric space and that f is continuous. Then the components of f are functionally dependent iff they are locally C^0-dependent.*

REMARK. The definition of functional dependence used by A. B. Brown [1] is essentially (i.e., modulo the irrelevance of p in C^p-dependence) the property given in Proposition 5, and so (since $\boldsymbol{R}^n$ is locally compact) is equivalent to our local C^0-dependence. Proposition 6 asserts the equivalence of Brown's definition with Buck's.

Proof of Proposition 6. Suppose that the components of f are functionally dependent. Then $\mathfrak{R}(f)$ has no interior point. Let $x \in X$ and choose a compact neighborhood K of x. *A fortiori*, $f[K]$ has no interior point, and being closed (as compact subset of a Hausdorff space) is nowhere dense. By Proposition 3, the components of $f|_K$ are C^0-dependent. Thus f has locally C^0-dependent components.

Conversely, supposing that f has locally C^0-dependent components, let (K_n) be a sequence of compact sets covering X. By Proposition 5, the components of $f|_{K_n}$ are C^0-dependent, hence (Proposition 2) $f[K_n]$ is nowhere dense, for every n. The sets $f[K_n]$ cover $\mathfrak{R}(f)$, so that $\mathfrak{R}(f)$ is meager (1st. category). Since Y is a Baire space (2nd. category), $\mathfrak{R}(f)$ has no interior point. The result follows from Proposition 1.

COROLLARY. *Let m, n be positive integers, $X \subset \boldsymbol{R}^n$ and let $f\colon X \to \boldsymbol{R}^m$ be continuous and have functionally dependent components. Then for any compact $K \subset X$ the components of $f|_K$ are C^∞-dependent.*

5. Functional dependence and vanishing Jacobians. The basic result of Brown and Sard mentioned in the introduction is as follows:

THEOREM 1. *Let m, n be positive integers, X an open subset of $\boldsymbol{R}^n$ and $f: X \to \boldsymbol{R}^m$ of class C^p for some $p \geqq 1$. Then*

(i) *if the components of f are functionally dependent, their Jacobian has rank less than m at every point of X;*

(ii) *the converse of* (i) *is true whenever $p \geqq \frac{1}{2}(n-m+2)$ (hence without class restrictions if $m \geqq n$).*

Before considering the proof of this theorem, we recall that the *differential* df_a of f is the linear function $u: \boldsymbol{R}^n \to \boldsymbol{R}^m$ (unique when it exists) such that

$$\lim_{x \to a} \frac{f(x) - f(a) - u(x-a)}{\|x-a\|} = 0,$$

where $\|\ \|$ denotes some norm on $\boldsymbol{R}^n$. Which norm is used is irrelevant since all norms on $\boldsymbol{R}^n$ are equivalent. The one most frequently used is the *Euclidean norm*, determined by $\|x\|^2 = \sum_{j=1}^n x_j^2$, where the x_j are the coordinates of x. We shall also use the *Cartesian norm*, defined by

$$\|x\| = \sup \{ |x_j| : 1 \leqq j \leqq n \}.$$

The continuity of df_a (which is automatic for a linear mapping between finite-dimensional spaces) is expressed by the existence of $M \in \boldsymbol{R}$ such that $\|df_a(x)\| \leqq M\|x\|$ for all $x \in \boldsymbol{R}^n$. The infimum of all such M has the same property and is denoted by $\|df_a\|$. The partial derivatives of the components of f at a are the elements of the Jacobian matrix of f at a, which is the matrix of the linear function df_a relative to the natural bases for $\boldsymbol{R}^n$ and $\boldsymbol{R}^m$. The rank of this Jacobian matrix is equal to the rank of the differential.

In the sequel, we use the following result, called by Dieudonné [3, p. 273] the

RANK THEOREM. *Let m, n, X, f, p be as in Theorem* 1, *and suppose given a point $a \in \mathfrak{D}(f)$ such that df_x is of constant rank r for all x in some neighborhood of a. Then there exist neighborhoods U_1, U_2 of* 0, *a in $\boldsymbol{R}^n$, neighborhoods V_1, V_2 of $f(a)$,* 0 *in $\boldsymbol{R}^m$ and functions $g: U_1 \to U_2$, $h: V_1 \to V_2$ with the following properties:*

(i) *$g(0) = a$, $h(f(a)) = 0$ and g, h are one-one and have ranges U_2, V_2 respectively,*

(ii) *g, g^{-1}, h, h^{-1} are of class C^p,*

(iii) *$h \circ f \circ g = df_{a|U_1}$,*

Moreover,

(iv) *if $r = n$ (in which case it is enough to be given that df_a has rank n, since then df_x will have rank n on some neighborhood of a: equivalently if df_a is one-one) then g can be chosen to be a translation in $\boldsymbol{R}^n$,*

(v) *if $r = m$ (equivalently, if df_a has range $\boldsymbol{R}^m$), then h can be chosen to be a translation in $\boldsymbol{R}^m$.*

Readers unfamiliar with this coordinate-free treatment are recommended to consult chapter 10 of [4].

Proof of (i). Suppose that, for some point $a \in X$, the differential df_a of f at a has rank m. Then we find from the rank theorem that $f[U_2] = h^{-1}[df_a[U_1]]$ is a neighborhood of $f(a)$, so that $f(a)$ is an interior point of $\mathfrak{R}(f)$. The assertion now follows from Proposition 1.

The proof of (ii) will not be given in full. We shall indicate what is involved, and supply references.

It is enough to prove that if K is a closed cube in X with sides parallel to the axes, then $f[K]$ has no interior point. The technique is to show that $f[K]$ lies in a set of arbitrarily small volume, from which it is obvious that it cannot have an interior point.

In fact, this proves more, namely that $f[K]$ has measure zero, where 'measure' means either Lebesgue measure in $\boldsymbol{R}^m$ or m-dimensional Hausdorff measure. We use a cube, because this can be subdivided into nonoverlapping cubes. For convenience, we use the Cartesian norm on $\boldsymbol{R}^n$, so that the cubes are 'balls' in the sense of this metric. On $\boldsymbol{R}^m$ we use the Euclidean norm since we wish to estimate volume.

According to the Mean Value theorem,

$$\|f(x) - f(a)\| \leqq M\|x - a\| \tag{1}$$

for all $x \in K$, $a \in K$, where $M = \sup\{\|df_x\| : x \in K\}$ is finite. In other words, distances are increased by a factor of at most M. Let Q be a cube in K with sides of length l parallel to the axes. Then $f[Q]$ lies inside a ball of radius $\frac{1}{2}Ml$, hence of volume $M_1 l^m$, where M_1 is independent of Q. Letting L denote the length of the sides of K and dividing K into N^n cubes with sides of length L/N, we see that $f[K]$ lies in a set of volume not exceeding $N^n M_1 (L/N)^m$ which is arbitrarily small for large enough N provided $m > n$. Thus the result is proved for this case.

If $m \leqq n$ we make more specific use of the hypothesis that the rank of the Jacobian is everywhere less than m. From the compactness of K, it follows that there exists an increasing function $b: \boldsymbol{R}_+ \to \boldsymbol{R}_+$ with $\lim_{\epsilon \to 0} b(\epsilon) = 0$ such that

$$\|f(x) - f(a) - df_a(x - a)\| \leqq b(\|x - a\|)\|x - a\| \tag{2}$$

whenever $x \in K$ and $a \in K$. For fixed a, the points $f(a) + df_a(x - a)$ all lie in a hyperplane H in $\boldsymbol{R}^m$ since $\mathfrak{R}(df_a)$ has dimension less than m. The above inequality shows that a cube of side l maps to a set of points no further than $lb(l)$ from H, hence into a hypercylinder of volume $M_2 l^{m-1} lb(l)$. Subdividing into N^n cubes of side L/N as above, we see that $f[K]$ lies in a set of volume $M_2 L^m N^{n-m} b(L/N)$, which is now arbitrarily small for large N when $m = n$.

The way to cope with the case $m < n$ is to modify the factor N^{n-m} in the estimate. We need to improve (1) to

$$\|f(x) - f(a)\| \leqq M\|x - a\|^q \tag{3}$$

so that a cube of side l maps into a ball of radius $M(l/2)^q$ and (with account taken of the rank of df) into a hypercylinder of volume $M_3 l^{q(m-1)} lb(l)$. This would

give the estimate $M_3L^{qm-q+1}N^{n-q(m-1)-1}b(L/N)$ which is good enough provided $n-q(m-1)-1\leqq 0$, i.e., $q\geqq(n-1)/(m-1)$, but an inequality of the form (3) for $q>1$ cannot be expected to hold very widely. Clearly, if it holds for all x in some neighborhood of a point a, we must have $df_a=0$. Moreover, when q is an integer, it suggests that the Taylor expansion of f about a has all terms of orders $1, 2, \cdots, q-1$ equal to 0, and that $M\|x-a\|^q$ estimates the remainder term. We expect therefore to need to assume f to be of class C^q as well as to consider points a at which $df_a=0$. Of course, if $df_x=0$ for all x in a ball, then f will be constant on that ball, and the image of the ball gives no trouble: our problem is to cope with $\{x\in X: df_x=0\}$, a closed set A which may be extremely complicated. Before stating the precise result, we observe that the isolated points of any subset of $\boldsymbol{R}^n$ are countable (and so have countable image), whilst the nonisolated points of A are accumulation points of points where df vanishes, and we may therefore expect a zero of higher order at such points.

LEMMA 1. *Let $A\subset X\subset\boldsymbol{R}^n$, X being open, and let p be a positive integer. Then there exists a sequence $(A_i)_{i\in N}$ of subsets of X such that*: (i) $A\subset\bigcup_{i\in N}A_i$, (ii) A_0 *is countable,* (iii) *For any $f: X\to\boldsymbol{R}$ of class C^p whose differential vanishes on A and any $i>0$, there exists an increasing function $b_i: \boldsymbol{R}_+\to\boldsymbol{R}_+$ such that $\lim_{\epsilon\to 0}b_i(\epsilon)=0$ and*

$$|f(x)-f(a)|\leqq b_i(\|x-a\|)\|x-a\|^p$$

whenever $x\in A_i$ and $a\in A_i$.

From this, as already indicated, we deduce

LEMMA 2. *Let X be an open subset of $\boldsymbol{R}^n$, let $f: X\to\boldsymbol{R}^m$ be of class C^p, and let $A=\{x\in X: df_x=0\}$. Then $f[A]$ is of measure zero, provided $p\geqq n/m$.*

The slight reduction (from $(n-1)/(m-1)$ to n/m) comes about because the M in (3) has become a $b_i(\|x-a\|)$ and we can therefore consider balls rather than hypercylinders. From this we obtain:

LEMMA 3. *Let X be an open subset of $\boldsymbol{R}^n$, let $f: X\to\boldsymbol{R}^m$ be of class C^p and let A_r be the set of points $x\in X$ at which the rank of df_x is $r(<m)$. Then $f[A_r]$ has measure zero provided that $p\geqq(n-r)/(m-r)$.*

For $r=0$ this is Lemma 2. For a point a where df_a has rank $r>0$, we let X_2 be the kernel of df_a, Y_1 the range of df_a and choose supplementary subspaces X_1, Y_2 in $\boldsymbol{R}^n$, $\boldsymbol{R}^m$ respectively. After a C^p change of coordinates (by applying the rank theorem to $\pi_1\circ f$, where π_1 is projection onto Y_1) we find that the restriction of the new function f^* (which is defined on a neighborhood N of 0) to any slice of N (formed by taking the intersection with N of some translate of X_2) has two properties: its range lies in the appropriate translate of Y_2 and its differential vanishes at any point corresponding (by the coordinate change) to a point of A_r. The dimensions of X_2, Y_2 being $n-r$, $m-r$ respectively, Lemma 2

applies to such restrictions to show that $f[A_r]$ meets every translate of Y_2 in a set of $(m-r)$-dimensional measure zero, and the result follows from Fubini's Theorem.

When the rank of df_x is less than m for all $x \in X$, we have $\mathfrak{R}(f) = \bigcup_{r=0}^{m-1} f[A_r]$ and so is of measure 0 (hence without interior point) provided $p \geqq (n-r)/(m-r)$ for $r = 0, 1, \cdots, m-1$, i.e., provided $p \geqq n-m+1$. The slight improvement in part (ii) of Theorem 1 comes from the observation that Lemma 3 is needed only for $r \leqq m-2$. That $f[A_{m-1}]$ has no interior point is immediate from the rank theorem, A_{m-1} being an open set on which the differential of f has constant rank $m-1$.

References. Lemma 1 was given in [6] Theorem 4.2. Lemmas 2 and 3 were given in [9]. There is also a full discussion of Sard's theorem, including Morse's lemma, in [10]. Sard's theorem is the corollary of Lemma 3 (without supposing the rank of the differential to be everywhere less than m) that the set $\bigcup_{r=2}^{m-1} f[A_r]$ has measure 0 provided $p \geqq n-m+1$. It is used in the study of immersions of manifolds and in the case $m = n$ is relevant to the change of variable in a multiple integral (cf. [5]).

REMARKS. 1. Although part (ii) of Theorem 1 is deduced from Sard's results, these results were designed to prove Sard's Theorem and do not use the hypothesis of Theorem 1 (ii) that every point is a critical point. Thus, although the lower bound on p in Sard's theorem cannot be improved (as shown by an example in [11]), that in Theorem 1 (ii) is obviously not the best possible for the (admittedly trivial) case $m = 1$. Presumably a new approach is needed.

2. Let m, n, X, f and p be as in Theorem 1. Suppose that $a \in X$ and $r < m$ are such that df_x has rank r for all x in some neighborhood of a. Then we can find neighbourhoods U, V of a, $b(=f(a))$ respectively and $F: V \to \boldsymbol{R}^{m-r}$ of class C^p such that $f[U] \subset V \subset \boldsymbol{R}^m$, $F \circ f|_U = 0$ and dF_a has rank $m-r$. (We have only to let π_2 be projection onto a supplement of the range of df_a and take $U = U_2$, $V = V_1$, $F = \pi_2 \circ h$ in the notation of the rank theorem.) The components of F therefore constitute $m-r$ independent relations between the components of $f|_U$: and these relations can be solved to give $m-r$ of the components of f in terms of the others. This is the usual textbook result, and it is used in the discussion of total differential equations (cf. [8] p. 141, for example).

It should be noted that without the hypothesis of constant rank these results may fail. For example, let $f = (f_1, f_2): \boldsymbol{R} \to \boldsymbol{R}^2$ be defined by

$$f_1(t) = \begin{cases} e^{-1/t^2} & (t > 0) \\ 0 & (t \leqq 0), \end{cases}$$

$f_2(t) = f_1(-t)$. Then f_1 and f_2 are analytically dependent (take $F(x, y) = xy$), but are not F-related on a neighborhood of the origin by any F of class C^1 for which dF_0 has rank 1. Nor is there any ϕ such that $f_1(t) = \phi(f_2(t))$ on some neighborhood of 0.

6. Analytic dependence. There is no general analogue of Theorem 1 above for analytic dependence, as is shown by the following example (cf. [7]).

Define $f: \mathbf{C}^2 \to \mathbf{C}^m$ for $m \geqq 3$ by

$$f(u, v) = (u, uv, uve_1(v), uve_2(u), \cdots, uve_{m-2}(v)),$$

where $e_1(v) = e^v$ and $e_k(v) = e^v e_{k-1}(e^v)$. Let F be a complex-valued analytic function on some neighborhood of 0 in $\mathbf{C}^m$ such that $F \circ f$ vanishes on some neighborhood of 0 in $\mathbf{C}^2$. We shall prove that F vanishes identically.

Collecting terms in the power series expansion of F about the origin, we can write

$$F = \sum_{n=0}^{\infty} F_n,$$

where F_n is a homogeneous polynomial function of total degree n in m variables. Composing with f, we have

$$\begin{aligned} F(f(u, v)) &= \sum_{n=0}^{\infty} F_n(u, uv, uve_1(v), \cdots, uve_{m-2}(v)) \\ &= \sum_{n=0}^{\infty} u^n F_n(1, v, ve_1(v), \cdots, ve_{m-2}(v)), \end{aligned}$$

a power series in u with coefficients depending on v. Since this vanishes on a neighborhood of 0 in $\mathbf{C}^2$, we conclude that the coefficient of each power of u vanishes on a neighborhood of 0 in $\mathbf{C}$, hence everywhere in $\mathbf{C}$ (since it is an entire function). Writing

$$F_n(y_1, y_2, \cdots, y_m) = \sum_{k=0}^{n} F_{nk}(y_2, y_3, \cdots, y_m) y_1^{n-k},$$

the F_{nk} are homogeneous polynomial functions of total degree k in $m-1$ variables and $\sum_{k=0}^{n} F_{nk}(v, ve_1(v), \cdots, ve_{m-2}(v)) = 0$ for all $v \in \mathbf{C}$. Hence

$$\sum_{k=0}^{n} v^k F_{nk}(1, e_1(v), \cdots, e_{m-2}(v)) = 0$$

for all $v \in \mathbf{C}$. Let $v_0 \in \mathbf{C}$. Then the polynomial function

$$v \longmapsto \sum_{k=0}^{n} v^k F_{nk}(1, e_1(v_0), \cdots, e_{m-2}(v_0))$$

vanishes for $v = v_0 + 2q\pi i$ for all $q \in \mathbf{Z}$, since e_k takes the same value at all such v. We conclude that it vanishes identically and since v_0 is arbitrary, that

$$F_{nk}(1, e_1(v), \cdots, e_{m-2}(v)) = 0$$

for all $v \in \mathbf{C}$. If we write $w = e^v$, this means that

$$F_{nk}(1, w, we_1(w), \cdots, we_{m-3}(w)) = 0$$

for all $w \in C \setminus \{0\}$, hence for all $w \in C$. But this is precisely what we had earlier, but with $m-1$ for m. It is therefore enough to consider the case $m=3$, for which we have

$$F_{nk}(1, w) = 0$$

for all $w \in C$. This gives $F_{nk}=0$ immediately, and completes the proof that $F=0$.

By defining g: $C^n \to C^m$ by $g(x_1, x_2, \cdots, x_n) = f(x_1, x_2)$ we see that:

If $n \geqq 2$ and $m \geqq 3$, the components of an analytic f: $C^n \to C^m$ whose differential has rank everywhere less than m may fail to be locally analytically dependent.

For the remaining cases, the positive result does hold. The case $m=1$ is trivial. The case $m=2$, was proved by A. B. Brown in [1]. The case $n=1$, $m>2$ follows from the case $m=2$ by using the first two components.

For the real analytic case, the same discussion as above gives the analogous negative results. The positive results follow from the complex case.

BOUNDS ON FUNCTIONS OF MATRICES

P. C. ROSENBLOOM, University of Minnesota and Minnesota State Department of Education

1. Introduction. If f is a function on a set S of scalars (real or complex) to the scalars, then the postulate, if $Ax=\lambda x$ and $\lambda \in S$, then

$$f(A)x = f(\lambda)x \tag{1}$$

uniquely defines the extension of f to the set S_n of all $n \times n$ matrices with distinct eigenvalues belonging to S. For various classes of functions f and sets S formulas

have been given for extending f to the set $\overline{S}_n$ of all matrices A such that the spectrum $\sigma(A) \subset S$. We investigate here the conditions on f that f have a bounded or a continuous extension to $\overline{S}_n$. In finite dimensional spaces all norms on the spaces of vectors or matrices are, of course, topologically equivalent.

Let $\| \cdot \cdot \cdot \|$ be any norm on the space of $n \times n$ matrices, and for $R > 0$ define

$$N_n(f; S, R) = \sup \|f(A)\| \quad \text{for } A \in S_n, \|A\| \leqq R.$$

Our first question is: when is the norm $N_n(f; S, R)$ finite?

For simplicity of exposition, we work out the cases $n = 2$ and $n = 3$, and then extend to general $n > 1$.

2. Case $n = 2$. Consider triangular matrices:

$$A = \begin{pmatrix} \lambda & a \\ 0 & \mu \end{pmatrix},$$

where $\lambda \neq \mu$, and $\lambda, \mu \in S$. If $\delta_1 = (1, 0)$ and $\delta_2 = (0, 1)$, then $A\delta_1 = \lambda\delta_1$, $A\delta_2 = a\delta_1 + \mu\delta_2$. Therefore we have $f(A)\delta_1 = f(\lambda)\delta_1$. Furthermore we find that

$$A(t\delta_1 + \delta_2) = \mu(t\delta_1 + \delta_2)$$

for $t = a/(\mu - \lambda)$, so that

$$\begin{aligned} f(A)\delta_2 &= f(A)(t\delta_1 + \delta_2 - t\delta_1) \\ &= f(\mu)(t\delta_1 + \delta_2) - tf(\lambda)\delta_1 \\ &= t(f(\mu) - f(\lambda))\delta_1 + f(\mu)\delta_2. \end{aligned}$$

Consequently, we obtain

$$f(A) = \begin{pmatrix} f(\lambda) & a[\lambda, \mu] \\ 0 & f(\mu) \end{pmatrix}, \quad \text{where} \quad [\lambda, \mu] = \frac{f(\lambda) - f(\mu)}{\lambda - \mu}$$

is the divided difference of f. If

$$C = \sup |a_{jk}| \tag{2}$$

for $\|A\| \leqq 1$, $A = (a_{jk})$, $1 \leqq j, k \leqq 2$, then

$$|f(\lambda)| \leqq C\|f(A)\|, \qquad |a||[\lambda, \mu]| \leqq C\|f(A)\|.$$

If $\|A\| \leqq R$, then $|f(\lambda)| \leqq CN_2(f; S, R)$, $|a||[\lambda, \mu]| \leqq CN_2(f; S, R)$.

Let

$$B = \sup \|A\| \tag{3}$$

for $A = (a_{jk})$, $\sum |a_{jk}| \leqq 1$.

The norms $m(A) = \sup |a_{jk}|$ and $n(A) = \sum |a_{jk}|$ are often computationally convenient. The relations $m(A) \leqq C\|A\|$ and $\|A\| \leqq Bn(A)$, where B and C depend only on n, are special cases of the topological equivalence of all norms. Then

$$\|A\| \leqq B(|\lambda| + |\mu| + |a|) \leqq R$$

if $|\lambda|, |\mu|, |a| \leqq R/(3B)$. We set $a = R/(3B)$, and obtain

$$|f(\lambda)| \leqq CN_2(f; S, R)$$

and $|[\lambda, \mu]| \leqq 3BC\, N_2(f; S, R)/R$ for $\lambda, \mu \in S, \lambda \neq \mu$, and $|\lambda|, |\mu| \leqq R/(3B)$.

THEOREM 1. *If $N_2(f; S, R) < +\infty$ for all $R > 0$, then f is bounded and Lipschitzian on every bounded subset of S. If*

$$M_1(f; S, r) = \sup(|f(\lambda)| + |[\lambda, \mu]|)$$

for $\lambda, \mu \in S, \lambda \neq \mu, |\lambda|, |\mu| \leqq r$, then

$$M_1(f; S, r) \leqq C(1 + r^{-1})N_2(f; S, 3Br). \tag{4}$$

COROLLARY 1a. *If f can be extended to a continuous function on $\overline{S}_2$, and S is a domain in the complex plane, then f is analytic in S. If $N_2(f; S, R) < \infty$ for all $R > 0$, then f' is bounded on every bounded subset of S.*

In order to obtain an estimate of $N_2(f; S, R)$ in terms of $M_1(f; S, R)$ we use, for the sake of simplicity, the Euclidean (unitary) length of 2-dimensional vectors

$$\|(x_1, x_2)\| = (|x_1|^2 + |x_2|^2)^{1/2},$$

and the corresponding norm $\|A\| = \sup \|Ax\|$ for $\|x\| \leqq 1$ for 2×2 matrices.

For a triangular matrix A, as above, this norm reduces to

$$\|A\|^2 = \frac{s^2 + \sqrt{s^4 - 4|\lambda|^2|\mu|^2}}{2},$$

where $s^2 = |\lambda|^2 + |\mu|^2 + |a|^2$, so that $s/\sqrt{2} \leqq \|A\| \leqq s$, $|\lambda| \leqq \|A\|$, $|\mu| \leqq \|A\|$.

If $A \in S_2$ and $\|A\| \leqq R$, where $R > 0$, then let λ and μ be the eigenvalues of A. Let x be an eigenvector belonging to λ, and let y be a unit vector perpendicular to x. Then in the coordinate system with base vectors x and y, the matrix A has the above triangular form.

We obtain therefore

$$\|f(A)\|^2 \leqq |f(\lambda)|^2 + |f(\mu)|^2 + |a|^2|[\lambda, \mu]|^2 \leqq (2 + 2R^2)M_1(f; S, R)^2.$$

THEOREM 2. *If $M_1(f; S, r) < +\infty$ for all $r > 0$, then $N_2(f; S, R) < +\infty$ for all $R > 0$, and $N_2(f; S, R) \leqq (2 + 2R^2)^{1/2} M_1(f; S, R)$.*

COROLLARY 2a. *For $N_2(f; S, R)$ to be finite for every $R > 0$ it is necessary and sufficient that f be bounded and Lipschitzian on every bounded subset of S.*

COROLLARY 2b. *For f to have a continuous extension to $\overline{S}_2$ it is necessary and sufficient that f be continuously differentiable on S. If f and f' are bounded on every bounded subset of S, then $N_2(f; S, R) < +\infty$ for all $R > 0$.*

3. Case $n=3$. In the same way, we find that if

$$A = \begin{pmatrix} \lambda & a & b \\ 0 & \mu & c \\ 0 & 0 & \nu \end{pmatrix},$$

where λ, μ, and ν are distinct elements of S, then

$$f(A) = \begin{pmatrix} f(\lambda) & a[\lambda, \mu] & b[\lambda, \nu] + ac[\lambda, \mu, \nu] \\ 0 & f(\mu) & c[\mu, \nu] \\ 0 & 0 & f(\nu) \end{pmatrix}.$$

We note that the second-order divided difference is defined by

$$[\lambda, \mu, \nu] = \frac{[\lambda, \mu] - [\lambda, \nu]}{\mu - \nu}.$$

If we define B and C analogously to (2) and (3) above, then we obtain

$$\begin{aligned} |f(\lambda)| &\leqq C\|f(A)\|, \\ |a||[\lambda, \mu]| &\leqq C\|f(A)\|, \\ |b[\lambda, \nu] + ac[\lambda, \mu, \nu]| &\leqq C\|f(A)\|. \end{aligned}$$

If $|\lambda|, |\mu|, |\nu|, |a|, |b|, |c| \leqq R/(6B)$, then $\|A\| \leqq R$, so that

$$|f(\lambda)| \leqq CN_3(f; S, R).$$

If we set $a=c=R/(4B)$ and $b=0$, we obtain

$$|[\lambda, \mu]| \leqq 4BCN_3(f; S, R)/R, \quad \text{and} \quad |[\lambda, \mu, \nu]| \leqq 16B^2CN_3(f; S, R)/R^2.$$

Let us define $M_2(f; S, r) = \sup (|f(\lambda)| + |[\lambda, \mu]| + |[\lambda, \mu, \nu]|)$ for λ, μ, and ν distinct elements of S and $|\lambda|, |\mu|, |\nu| \leqq r$.

THEOREM 3. *If $N_3(f; S, R) < \infty$ for all $R>0$, then f is continuously differentiable and f' is Lipschitzian on every bounded subset of S, and*

$$M_2(f; S, r) \leqq \left(1 + \frac{2}{3r} + \frac{4}{9r^2}\right) CN_3(z; S, 6Br) \tag{5}$$

for $r>0$.

If the second-order divided differences are bounded, then $[\lambda, \nu]$ is continuous in λ, and $f'(\lambda) = \lim_{\mu \to \lambda} [\lambda, \mu]$ exists for $\lambda \in S$.

If, in the identity $[\lambda, \mu] - [\nu, \sigma] = [\lambda, \mu] - [\nu, \mu] + [\nu, \mu] - [\nu, \sigma]$, we let $\mu \to \lambda$ and $\nu \to \sigma$, we obtain

$$f'(\lambda) - f'(\sigma) = f'(\lambda) - [\sigma, \lambda] + [\sigma, \lambda] - f'(\sigma).$$

If $M_2(f; S, r) < +\infty$ and $|\lambda|, |\mu|, |\nu|, |\sigma| \leqq r$, then we infer that

$$|[\lambda, \mu] - [\nu, \sigma]| \leqq (|\lambda - \nu| + |\mu - \sigma|) M_2(f; S, r)$$

and

$$|f'(\lambda) - f'(\sigma)| \leqq 2|\lambda - \sigma| M_2(f; S, r).$$

In order to prove the converse of Theorem 3, we first note that there is an orthonormal basis x_1, x_2, x_3 (mutually orthogonal unit vectors) with respect to which A takes on the above triangular form:

$$Ax_1 = \lambda x_1$$
$$Ax_2 = ax_1 + \mu x_2,$$
$$Ax_3 = bx_1 + cx_2 + \nu x_3.$$

Indeed, if $\det(A - \lambda I) = 0$, then there is a unit vector x_1 such that $Ax_1 = \lambda x_1$. Let $A_1 x = Ax - (Ax, x_1)x_1$, where (x, y) is the scalar product of x and y. Then A_1 is a 2×2 matrix representing a linear transformation of the 2-dimensional space of vectors orthogonal to x_1 into itself. If an orthonormal base is chosen for this subspace so that A_1 has triangular form, then we obtain the desired form for A.

If we again use the Euclidean norms for vectors and matrices, we obtain

$$s/\sqrt{3} \leqq \|A\| \leqq s, \qquad |\lambda| \leqq \|A\|, \qquad |\mu| \leqq \|A\|, \qquad |\nu| \leqq \|A\|,$$

where $s^2 = |\lambda|^2 + |\mu|^2 + |\nu|^2 + |a|^2 + |b|^2 + |c|^2$.

Suppose that $M_2(f; S, r) < +\infty$ for all $r > 0$, that $A \in S_3$, and that $\|A\| \leqq R$, where $R > 0$. Then

$$\|f(A)\|^2 \leqq M_2(f; S, R)^2(3 + |a|^2 + |c|^2 + (|b| + |ac|)^2)$$
$$\leqq M_2(f; S, R)^2(3 + s^2 + 2s^3 + s^4),$$

so that $\|f(A) \leqq M_2(f; S, R)(3 + 6R^2 + 18R^4)^{1/2}$.

THEOREM 4. *If $M_2(f; S, R) < +\infty$, then so is $N_3(f; S, R)$, and $N_3(f; S, R) \leqq (3 + 6R^2 + 18R^4)^{1/2} M_2(f; S, R)$.*

COROLLARY 4a. *For the extension of f to S_3 to be bounded on every bounded subset of S_3, it is necessary for f and its divided differences of order $\leqq 2$ to be bounded on every bounded subset of S.*

COROLLARY 4b. *If $N_3(f; S, R) < +_1\infty$ for all $R > 0$, then f can be extended to a continuous function on $\overline{S}_2$. If S is a domain in the complex plane and $N_3(f; S, R) < +\infty$ for all $R > 0$, then f is analytic in S.*

4. Any $n > 1$. The same methods can be applied to any $n > 1$. If $x_1, \cdots, x_n$ is a set of linearly independent vectors in n-space, and

$$Ax_k = \sum_{j<\kappa} a_{jk} x_j + \lambda_\kappa x_k, \qquad 1 \leqq k \leqq n, \tag{6}$$

where $\lambda_k \in S (1 \leqq k \leqq n)$, and the λ's are distinct, then

$$f(A)x_k = \sum_{j<k} b_{jk}x_k + f(\lambda_k)x_k, \qquad 1 \leqq k \leqq n, \tag{7}$$

where for $1 \leqq k < j$

$$b_{jk} = \sum a_{r_1r_2}a_{r_2r_3} \cdots a_{r_{m-1}r_m}[\lambda_{r_1}, \lambda_{r_2}, \cdots, \lambda_{r_m}],$$

the sum being taken over all sequences $(r_1, \cdots, r_m)$ such that

$$j = r_1 < r_2 < \cdots < r_{m-1} < r_m = k.$$

The nth order divided difference may be defined by

$$[\lambda_1, \cdots, \lambda_n] = \frac{[\lambda_1, \cdots, \lambda_{n-2}, \lambda_{n-1}] - [\lambda_1, \cdots, \lambda_{n-2}\lambda_n]}{\lambda_{n-1} - \lambda_n}.$$

Equation (7) can be proved by induction. If B and C are defined as before, then

$$\|A\| \leqq B(\sum |a_{jk}| + \sum |\lambda_k|) \leqq R$$

if $|a_{jk}| \leqq 2R/n(n+1)B = r$, $|\lambda_k| \leqq r$, for $1 \leqq j < k \leqq n$. Then

$$|f(\lambda_k)| \leqq C\|f(A)\|, \qquad |b_{jk}| \leqq C\|f(A)\|,$$

for $1 \leqq j < k \leqq n$. Set $a_{pq} = r$ if $q = p+1$, $1 \leqq p < n$, and $a_{pq} = 0$ otherwise. Then $b_{1m} = r^{m-1}[\lambda_1, \cdots, \lambda_m]$, so that we infer $|[\lambda_1, \cdots, \lambda_m]| \leqq C\|f(A)\|/r^{m-1}$ if $|\lambda_k| \leqq r$ for $1 \leqq k \leqq m$.

If we define

$$M_{n-1}(f; S, r) = \sup (|f(\lambda_1)| + |[\lambda_1, \lambda_2]| + \cdots + |[\lambda_1, \cdots, \lambda_n]|)$$

for $\lambda_1, \cdots, \lambda_n$ distinct elements of S and $|\lambda_k| \leqq r$ for $1 \leqq k \leqq n$, then

$$M_{n-1}(f; S, r) \leqq \left(\sum_0^{n-1} r^{-k}\right) CN_n(f; S, Bn(n+1)r/2).$$

We also prove by induction that an orthonormal base $x_1, \cdots, x_n$ of vectors can be chosen so that A satisfies (6). Then $f(A)$ is given by (7).

Now we have

$$|a_{jk}| = |(x_j, Ax_k)| \leqq \|x_j\|\|Ax_k\| \leqq \|A\|,$$
$$|\lambda_k| = |(x_k, Ax_k)| \leqq \|A\|.$$

Therefore if $\|A\| \leqq R$, then $|b_{jk}| \leqq (1+R^{n-1})M_{n-1}(f; S, R)$, and it follows that

$$\|f(A)\| \leqq n(1 + R^{n-1})M_{n-1}(f; S, R).$$

THEOREM 5. *The function f can be extended to a bounded function on every bounded part of $S_n (n \geqq 3)$ if and only if f and all divided differences of order $\leqq n$ are bounded on every bounded part of S.*

Then f is of class C^{n-2} on S and $f^{(n-2)}$ is Lipschitzian on every bounded part of S.

If S is convex and $f^{(k)}$ exists and is bounded for $1 \leqq k \leqq n-2$ and $f^{(n-2)}$ is Lipschitzian on every bounded part of S, then f can be extended to a continuous function on every bounded part of $\overline{S}_n$.

A MIXED DOUBLES TOURNAMENT PROBLEM

C. C. YALAVIGI, Government College, Mercara, India

Introduction. This paper concerns the design of mixed tournaments which are open to an equal number of men and women. In each match of a tournament two teams each containing 2^s men players and 2^s women players (where s denotes an integer $\geqq 0$) compete with one another. The available literature on designing mixed tournaments (see E. N. Gilbert [2]) shows that the added requirement of a team to contain 2^s men and 2^s women (for $s \neq 0$) does not seem to have been considered.

For scoring purposes ordinary tournaments in which each match consists of 2^{s+1} players (where $s \neq 0$) are designed for a high degree of symmetry e.g. each player appears with every other player 2^s-1 times as a teammate and 2^s times as an opponent. In a mixed tournament these symmetries hold separately for men players and women players. Moreover, if men players are denoted by 1, 2, $\cdots$, v and women players by $1^{(a)}$, $2^{(a)}$, $\cdots$, $v^{(a)}$, players of the same number never meet. To be more precise, a high degree constraint of a mixed tournament will be

I. (a) each player shall appear with every other player of the same sex exactly 2^s-1 times as a teammate and 2^s times as an opponent.
 (b) each player shall appear with every player of the opposite sex (except the player with the same number) exactly 2^s times as a teammate and 2^s times as an opponent.

In the design of a tournament subject to I, the total number of matches b is given by

$$b = v(v-1)/(2^{s+1}). \tag{1.1}$$

To prove (1.1) it is sufficient to note that the total number of appearances of men players is 2^{s+1} in a single match and $v(v-1)$ in all the matches.

Clearly the equation (1.1) restricts the number of players admissible to a tournament and designs are possible only for some forms of v.

2. Design for I with v a power of an odd prime in the form $4t+1$ and $s=0$. Let $v=4t+1=p^n$ where p denotes an odd prime and n an integer $\geqq 1$. In

constructing the designs of this section we will use a technique involving incomplete balanced block designs which is due to R. C. Bose [1].

We identify the players with the elements of GF $(4t+1)$. Construct a set of $2t$ generators

$$G_j = (A_j, B_j^{(a)}; X_j, Y_j^{(a)}) \qquad j = 0, 1, \cdots, 2t-1, \tag{2.1}$$

where A_j, X_j, denote men players, $B_j^{(a)}$, $Y_j^{(a)}$, denote women players, and $A_jB_j^{(a)}$ and $X_jY_j^{(a)}$, form two teams which play against one another.

From these generators, we may derive all the matches of a tournament, i.e.,

$$G_j(\alpha) = (A_j+\alpha, B_j^{(a)}+\alpha; X_j+\alpha, Y_j^{(a)}+\alpha) \qquad j = 0, 1, \cdots, 2t-1, \tag{2.2}$$

where α runs through all elements of GF$(4t+1)$.

These matches will not satisfy I unless certain conditions are fulfilled by four sets of numbers called the MM, WW, MW_t and MW_0 differences. They are

MM differences $= A_j - X_j$
WW differences $= B_j^{(a)} - Y_j^{(a)}$
MW_t differences $= A_j - B_j^{(a)}$ and $X_j - Y_j^{(a)}$
MW_0 differences $= Y_j^{(a)} - A_j$ and $B_j^{(a)} - X_j$.

These differences must satisfy the hypothesis of the following theorem.

THEOREM 1. *A mixed doubles tournament of this section when generated by a set of $2t$ generators $G_0, G_1 \cdots, G_{2t-1}$, in the manner prescribed above, satisfies* I *if and only if:*

(i) *the MM_t differences are in $2t$ distinct sets of 2^s-1 equal differences except $s=0$ and 1 where no two differences are equal for $s=1$,*
(ii) *the WW_t differences are in $2t$ distinct sets of 2^s-1 equal differences except $s=0$ and 1 where no two differences are equal for $s=1$,*
(iii) *no two of the $4t$ MW_t differences are equal,*
(iv) *no two of the $4t$ MW_0 differences are equal,*
(v) *none of the MM, WW, MW_t and MW_0 differences is zero.*

The proof is left to the reader. We proceed to construct a system of generators satisfying the conditions of Theorem 1.

Let

$$G_j = (x^{0+j}, x^{3t+j}; x^{2t+j}, x^{t+j}) \qquad j = 0, 1, \cdots, 2t-1, \tag{2.3}$$

where x denotes a primitive root in GF$(4t+1)$.

We have the following differences.

$$\begin{aligned} &A_j - B_j^{(a)} = x^{0+j} - x^{3t+j}, \quad A_j - X_j = x^{0+j} - x^{2t+j}, \quad X_j - Y_j^{(a)} = x^{2t+j} - x^{t+j}, \\ &B_j^{(a)} - Y_j^{(a)} = x^{3t+j} - x^{t+j}, \quad Y_j^{(a)} - A_j = x^{t+j} - x^{0+j}, \quad B_j^{(a)} - X_j = x^{3t+j} - x^{2t+j}. \end{aligned} \tag{2.4}$$

These differences must satisfy

$$
\begin{aligned}
&\text{(i)}' && x^{0+i}-x^{2t+i}\neq x^{0+j}-x^{2t+j} && \text{for } i\neq j\\
&\text{(ii)}' && x^{3t+i}-x^{t+i}\neq x^{3t+j}-x^{t+j} && \text{for } i\neq j\\
&\text{(iii)}'\text{A}. && x^{0+i}-x^{3t+i}\neq x^{0+j}-x^{3t+j},\quad x^{2t+i}-x^{t+i}\neq x^{2t+j}-x^{t+j}, && \text{for } i\neq j\\
&\text{(2.5)} \qquad \text{B}. && x^{0+i}-x^{3t+i}\neq x^{2t+j}-x^{t+j} && \text{for } i=j \text{ and } i\neq j\\
&\text{(iv)}'\text{A}. && x^{t+i}-x^{0+i}\neq x^{t+j}-x^{0+j},\ x^{3t+i}-x^{2t+i}\neq x^{3t+j}-x^{2t+j}, && \text{for } i\neq j\\
&\qquad\quad \text{B}. && x^{t+i}-x^{0+i}\neq x^{3t+j}-x^{2t+j} && \text{for } i=j \text{ and } i\neq j\\
&\text{(v)}' && x^{0+j}-x^{3t+j}\neq 0,\quad x^{0+j}-x^{2t+j}\neq 0,\quad x^{2t+j}-x^{t+j}\neq 0,\\
& && x^{3t+j}-x^{t+j}\neq 0,\quad x^{t+j}-x^{0+j}\neq 0,\quad x^{3t+j}-x^{2t+j}\neq 0,
\end{aligned}
$$

where $i=0, 1, \cdots, 2t-1$.

The proof of these inequalities is as follows.

Let the inequalities (i)', (ii)', (iii)'A and (iv)'A be expressed as

$$Ax^i \neq Ax^j, \qquad i \neq j, \tag{2.6}$$

where A denotes a related constant.

The proof of (2.6) requires $x^{i-j}\neq 1$ for $i\neq j$. This is true because $i-j\not\equiv 0 \bmod(4t)$.

Consider the inequalities (iii)'B and (iv)'B. It is easy to rewrite (iii)'B as

$$(x^{4t+i} - x^{3t+i}) \neq (x^{2t+j} - x^{t+j}). \tag{2.7}$$

This is true since $x^{2t}=-1$ and $x^{i-j}\neq -1$. The proof of (iv)'B is similar.

For the proof of (v)', note that $x, x^2, x^3, \cdots, x^{4t}=1$ are all different.

Hence (2.3) satisfies the conditions of Theorem 1. As illustrations, three designs follow.

Set of generators of mixed doubles tournaments for $v=4t+1=p$

v Generators

13 $(1, 5^{(a)}; 12, 8^{(a)})$, $(2, 10^{(a)}; 11, 3^{(a)})$, $(4, 7^{(a)}; 9, 6^{(a)})$, $(8, 1^{(a)}; 5, 12^{(a)})$, $(3, 2^{(a)}; 10, 11^{(a)})$, $(6, 4^{(a)}; 7, 9^{(a)})$

17 $(1, 3^{(a)}; 16, 14^{(a)})$, $(3, 9^{(a)}; 14, 8^{(a)})$, $(9, 10^{(a)}; 8, 7^{(a)})$, $(10, 13^{(a)}; 7, 4^{(a)})$, $(13, 5^{(a)}; 4, 12^{(a)})$, $(5, 15^{(a)}; 12, 2^{(a)})$, $(15, 11^{(a)}; 2, 6^{(a)})$, $(11, 16^{(a)}; 6, 1^{(a)})$.

For $v=3^2$ we represent GF(9) by the residues mod $(3, x^2+x+2)$. The set of generators is therefore

$(1, (x+2)^{(a)}; 2, (2x+1)^{(a)})$, $(x, (x+1)^{(a)}; 2x, (2x+2)^{(a)})$, $(2x+1, 1^{(a)}; x+2, 2^{(a)})$, $(2x+2, x^{(a)}; x+1, (2x)^{(a)})$.

This set of generators is developed by adding x, $2x+1$, $2x+2$, 2, $2x$, $x+2$, $x+1$, 1.

We may note that the designs of this section are also produced by another set of generators, viz.,

$$G_j = (x^{0+j}, x^{1+j}; x^{2t+j}, x^{2t+1+j}) \qquad j = 0, 1, \cdots, 2t-1.$$

This set of generators satisfies Theorem 1. The proof is left to the reader.

3. Design for I with v a power of an odd prime in the form $4t-1$ and $s=0$.

This section will develop designs of mixed doubles tournaments for $v=4t-1=p^n$. These designs will use the method of Section 2.

We give the following theorem.

THEOREM 2. *A mixed doubles tournament of this section when generated by a set of* $2t-1$ *generators* $G_0, G_1 \cdots, G_{2t-2}$ *in the manner prescribed as in Section* 2 *satisfies* I *if and only if:*

(i) *no two of the* $2t-1$ MM *differences are equal,*
(ii) *no two of the* $2t-1$ WW *differences are equal,*
(iii) *no two of the* $4t-2$ MW_t *differences are equal,*
(iv) *no two of the* $4t-2$ MW_0 *differences are equal,*
(v) *none of the* MM, WW, MW_t *and* MW_0 *differences is zero.*

The proof is left to the reader. A system of $2t-1$ generators satisfying the conditions of Theorem 2 may be represented as

$$G_j = (x^{0+j}, x^{1+j}; x^{2t-1+j}, x^{2t+j}) \qquad j = 0, 1, \cdots, 2t-2 \tag{3.1}$$

where x denotes a primitive root in GF$(4t-1)$.

For these generators the differences are

$$\begin{aligned} &A_j-B_j^{(a)}=x^{0+j}-x^{1+j}, \quad X_j-Y_j^{(a)}=x^{2t-1+j}-x^{2t+j}, \quad A_j-X_j=x^{0+j}-x^{2t-1+j}, \\ &B_j^{(a)}-Y_j^{(a)}=x^{1+j}-x^{2t+j}, \quad B_j^{(a)}-X_j=x^{1+j}-x^{2t-1+j}, \quad Y_j^{(a)}-A_j=x^{2t+j}-x^{0+j}. \end{aligned} \tag{3.2}$$

These differences must satisfy

$$\begin{aligned}
&\text{(i)}' \quad x^{0+i}-x^{2t-1+i}\neq x^{0+j}-x^{2t-1+j}, \quad \text{for } i\neq j \\
&\text{(ii)}' \quad x^{1+i}-x^{2t+i}\neq x^{1+j}-x^{2t+j}, \quad \text{for } i\neq j \\
&\text{(iii)}'\text{A.} \quad x^{0+i}-x^{1+i}\neq x^{0+j}-x^{1+j}, \quad x^{2t-1+i}-x^{2t+i}\neq x^{2t-1+j}-x^{2t+j}, \quad \text{for } i\neq j \\
&\quad\text{B.} \quad x^{0+i}-x^{1+i}\neq x^{2t-1+j}-x^{2t+j}, \quad \text{for } i=j \text{ and } i\neq j \\
&\text{(iv)}'\text{A.} \quad x^{1+i}-x^{2t-1+i}\neq x^{1+j}-x^{2t-1+j}, \quad x^{2t+i}-x^{0+i}\neq x^{2t+j}-x^{0+j}, \quad \text{for } i\neq j \\
&\quad\text{B.} \quad x^{1+i}-x^{2t-1+i}\neq x^{2t+j}-x^{0+j}, \quad \text{for } i=j \text{ and } i\neq j \\
&\text{(v)}' \quad x^{0+j}-x^{1+j}\neq 0, \quad x^{2t-1+j}-x^{2t+j}\neq 0, \quad x^{0+j}-x^{2t-1+j}\neq 0, \quad x^{1+j}-x^{2t+j}\neq 0, \\
&\qquad x^{1+j}-x^{2t-1+j}\neq 0, \quad x^{0+j}-x^{2t+j}\neq 0,
\end{aligned} \tag{3.3}$$

where $i=0, 1, \cdots, 2t-2$.

The proof of these inequalities is as follows: We express (i)', (ii)', (iii)'A and (iv)'A in the form $Ax^i\neq Ax^j$, $i\neq j$, where A denotes a related constant.

This inequality holds true if $x^{i-j}\neq 1$ for $i\neq j$ which is easily verifiable.

The inequalities (iii)'B and (iv)'B are similar. We may obtain (iii)'B from $x^{i-j}\cdot x^{2t-1}\neq 1$ which is true since $x^{i-j}\neq -1$ and $x^{2t-1}=-1$. The proof of (iv)'B is left to the reader.

For proving (v)', we note that $x, x^2, \cdots, x^{4t-2}=1$ are all different.

Hence the considered set of generators satisfies the conditions of Theorem 2. We give the following illustrations.

Set of generators of mixed doubles tournaments for $v=4t-1=p$

v	Generators
7	$(1, 3^{(a)}; 6, 4^{(a)}), (3, 2^{(a)}; 4, 5^{(a)}), (2, 6^{(a)}; 5, 1^{(a)})$
11	$(1, 2^{(a)}; 10, 9^{(a)}), (2, 4^{(a)}; 9, 7^{(a)}), (4, 8^{(a)}; 7, 3^{(a)}),$ $(8, 5^{(a)}; 3, 6^{(a)}), (5, 10^{(a)}; 6, 1^{(a)}).$

The designs of Sections 2 and 3 may also use the sets of generators for $v=6t\pm1$. For $v=6t+1$ they are

$$G_j = (x^{0+j}, x^{1+j}; x^{3t+j}, x^{3t+1+j}) \qquad j = 0, 1, \cdots, 3t-1,$$

and for $v=6t-1$ they are

$$G_j = (x^{0+j}, x^{1+j}; x^{3t-1+j}, x^{3t+j}) \qquad j = 0, 1, \cdots, 3t-2.$$

The proofs for these sets of generators are similar to those described in Sections 2 and 3.

This alternate method gives all the solutions of Sections 2 and 3 except $v=3^n$.

4. Design for I with v a power of an odd prime in the form $4t+1$ and $s=1$.

This section will develop designs of mixed tournaments for $v=4t+1=p^n$ where p denotes an odd prime and n an integer $\geqq 1$. In each match four men players and four women players participate.

In the design of these tournaments, a generator is an eight-tuple $G'_{j'}=(A_{j'}, B_{j'}^{(a)}, C_{j'}, D_{j'}^{(a)}; X_{j'}, Y_{j'}^{(a)}, Z_{j'}, W_{j'}^{(a)})$ which is a suitable combination of two quadruple generators. Clearly a set of t generators specifies all the matches of a tournament. It therefore remains to characterize the set of generators which will produce the design of this section.

We associate with each generator six sets of numbers called the MM_t, MM_0, WW_t, WW_0, MW_t and MW_0 differences as follows:

MM_t differences $=A_{j'}-C_{j'}$ and $X_{j'}-Z_{j'}$

MM_0 differences $=A_{j'}-X_{j'}$, $A_{j'}-Z_{j'}$, $X_{j'}-C_{j'}$ and $Z_{j'}-C_{j'}$

WW_t differences $=B_{j'}^{(a)}-D_{j'}^{(a)}$ and $Y_{j'}^{(a)}-W_{j'}^{(a)}$

WW_0 differences $=B_{j'}^{(a)}-Y_{j'}^{(a)}$, $B_{j'}^{(a)}-W_{j'}^{(a)}$, $Y_{j'}^{(a)}-D_{j'}^{(a)}$ and $W_{j'}^{(a)}-D_{j'}^{(a)}$

MW_t differences $=A_{j'}-B_{j'}^{(a)}$, $D_{j'}^{(a)}-C_{j'}$, $X_{j'}-Y_{j'}^{(a)}$, $W_{j'}^{(a)}-Z_{j'}$, $A_{j'}-D_{j'}^{(a)}$, $B_{j'}^{(a)}-C_{j'}$, $X_{j'}-W_{j'}^{(a)}$ and $Y_{j'}^{(a)}-Z_{j'}$

MW_0 differences $=A_{j'}-Y_{j'}^{(a)}$, $A_{j'}-W_{j'}^{(a)}$, $Y_{j'}^{(a)}-C_{j'}$, $W_{j'}^{(a)}-C_{j'}$, $B_{j'}^{(a)}-Z_{j'}$, $X_{j'}-D_{j'}^{(a)}$, $B_{j'}^{(a)}-X_{j'}$ and $Z_{j'}-D_{j'}^{(a)}$.

These differences must satisfy the hypothesis of the following theorem.

THEOREM 3. *A mixed tournament of this section when generated by a set of t generators $G'_0, G'_1, \cdots, G'_{t-1}$ in the manner prescribed above satisfies* I, *if and only if:*

(i) *no two of the* $2t$ MM_t *differences are equal,*

(ii) *no two of the* $2t$ WW_t *differences are equal,*

(iii) *the MW_t differences are equal in $4t$ distinct pairs,*
(iv) *the MW_0 differences are equal in $4t$ distinct pairs,*
(v) *the MM_0 differences are equal in $2t$ distinct pairs,*
(vi) *the WW_0 differences are equal in $2t$ distinct pairs,*
(vii) *none of the MM_t, MM_0, WW_t, WW_0, MW_t and MW_0 differences is zero.*

The proof is left to the reader. We proceed to construct a system of generators satisfying Theorem 3. Let

$$G_{j'}' = (x^{0+j'}, x^{1+j'}, x^{2t+j'}, x^{2t+1+j'}; x^{t+j'}, x^{t+1+j'}, x^{3t+j'}, x^{3t+1+j'}), \tag{4.1}$$

where $j'=0, 1, \cdots, t-1$ and x denotes a primitive root of GF$(4t+1)$. Clearly

$$\begin{aligned}
&A_{j'} - X_{j'} = x^{0+j'} - x^{t+j'}, && A_{j'} - Y_{j'}^{(a)} = x^{0+j'} - x^{t+1+j'},\\
&A_{j'} - Z_{j'} = x^{0+j'} - x^{3t+j'}, && A_{j'} - W_{j'}^{(a)} = x^{0+j'} - x^{3t+1+j'},\\
&B_{j'}^{(a)} - X_{j'} = x^{1+j'} - x^{t+j'}, && B_{j'}^{(a)} - Y_{j'}^{(a)} = x^{1+j'} - x^{t+1+j'},\\
&B_{j'}^{(a)} - Z_{j'} = x^{1+j'} - x^{3t+j'}, && B_{j'}^{(a)} - W_{j'}^{(a)} = x^{1+j'} - x^{3t+1+j'},\\
&X_{j'} - C_{j'} = x^{t+j'} - x^{2t+j'}, && Y_{j'}^{(a)} - C_{j'} = x^{t+1+j'} - x^{2t+j'},\\
&Z_{j'} - C_{j'} = x^{3t+j'} - x^{2t+j'}, && W_{j'}^{(a)} - C_{j'} = x^{3t+1+j'} - x^{2t+j'},\\
&X_{j'} - D_{j'}^{(a)} = x^{t+j'} - x^{2t+1+j'}, && Y_{j'}^{(a)} - D_{j'}^{(a)} = x^{t+1+j'} - x^{2t+1+j'},\\
&Z_{j'} - D_{j'}^{(a)} = x^{3t+j'} - x^{2t+1+j'}, && W_{j'}^{(a)} - D_{j'}^{(a)} = x^{3t+1+j'} - x^{2t+1+j'},\\
&X_{j'} - Y_{j'}^{(a)} = x^{t+j'} - x^{t+1+j'}, && X_{j'} - Z_{j'} = x^{t+j'} - x^{3t+j'},\\
&X_{j'} - W_{j'}^{(a)} = x^{t+j'} - x^{3t+1+j'}, && Y_{j'}^{(a)} - Z_{j'} = x^{t+1+j'} - x^{3t+j'},\\
&Y_{j'}^{(a)} - W_{j'}^{(a)} = x^{t+1+j'} - x^{3t+1+j'}, && W_{j'}^{(a)} - Z_{j'} = x^{3t+1+j'} - x^{3t+j'},\\
&A_{j'} - B_{j'}^{(a)} = x^{0+j'} - x^{1+j'}, && A_{j'} - C_{j'} = x^{0+j'} - x^{2t+j'},\\
&A_{j'} - D_{j'}^{(a)} = x^{0+j'} - x^{2t+1+j'}, && B_{j'}^{(a)} - C_{j'} = x^{0+j'} - x^{2t+j'},\\
&B_{j'}^{(a)} - D_{j'}^{(a)} = x^{1+j'} - x^{2t+1+j'}, && D_{j'}^{(a)} - C_{j'} = x^{2t+1+j'} - x^{2t+j'}.
\end{aligned} \tag{4.2}$$

The conditions of Theorem 3 therefore imply that

$$\begin{aligned}
&\text{(i)'a.}\quad x^{0+i'} - x^{2t+i'} \neq x^{0+j'} - x^{2t+j'}, && x^{t+i'} - x^{3t+i'} \neq x^{t+j'} - x^{3t+j'},\\
&\text{b.}\quad x^{0+i'} - x^{t+i'} \neq x^{0+j'} - x^{t+j'}, && x^{0+i'} - x^{3t+i'} \neq x^{0+j'} - x^{3t+j'},\\
&\quad x^{2t+i'} - x^{t+i'} \neq x^{2t+j'} - x^{t+j'}, && x^{2t+i'} - x^{3t+i'} \neq x^{2t+j'} - x^{3t+j'},\\
&\text{c.}\quad x^{1+i'} - x^{2t+1+i'} \neq x^{1+j'} - x^{2t+1+j'}, && x^{t+1+i'} - x^{3t+1+i'} \neq x^{t+1+j'} - x^{3t+1+j'},\\
&\text{d.}\quad x^{1+i'} - x^{t+1+i'} \neq x^{1+j'} - x^{t+1+j'}, && x^{1+i'} - x^{3t+1+i'} \neq x^{1+j'} - x^{3t+1+j'},\\
&\quad x^{2t+1+i'} - x^{t+1+i'} \neq x^{2t+1+j'} - x^{t+1+j'},\\
&\quad x^{2t+1+i'} - x^{3t+1+i'} \neq x^{2t+1+j'} - x^{3t+1+j'},\\
&\quad \text{for } i' \neq j' \text{ and } i' = 0, 1, \cdots, t-1
\end{aligned} \tag{4.3}$$

$$
\begin{aligned}
&\text{(ii)}' \quad x^{0+j'}-x^{1+j'}=x^{2t+1+j'}-x^{2t+j'}, && x^{0+j'}-x^{2t+1+j'}=x^{1+j'}-x^{2t+j'},\\
&\qquad x^{t+j'}-x^{t+1+j'}=x^{3t+1+j'}-x^{3t+j'}, && x^{t+j'}-x^{3t+1+j'}=x^{t+1+j'}-x^{3t+j'},\\
&\text{(iii)}' \quad x^{0+j'}-x^{t+1+j'}=x^{3t+1+j'}-x^{2t+j'}, && x^{0+j'}-x^{3t+1+j'}=x^{t+1+j'}-x^{2t+j'},\\
(4.3)\qquad & x^{1+j'}-x^{3t+j'}=x^{t+j'}-x^{2t+1+j'}, && x^{1+j'}-x^{t+j'}=x^{3t+j'}-x^{2t+1+j'},\\
&\text{(iv)}' \quad x^{0+j'}-x^{t+j'}=x^{3t+j'}-x^{2t+j'}, && x^{0+j'}-x^{3t+j'}=x^{t+j'}-x^{2t+j'},\\
&\text{(v)}' \quad x^{1+j'}-x^{t+1+j'}=x^{3t+1+j'}-x^{2t+1+j'}, && x^{1+j'}-x^{3t+1+j'}=x^{t+1+j'}-x^{2t+1+j'},
\end{aligned}
$$

(vi)′ none of the differences (4.2) is zero.

The proof of (4.3) is as follows: Let the inequalities (i)′ be of the form

$$A'x^{i'} \neq A'x^{j'}, \qquad i' = j' \tag{4.4}$$

where A' denotes a related constant.

The proof of this inequality requires $x^{i'-j'} \neq \pm 1$ for $i' \neq j'$. This is true since $i'-j' \not\equiv 0 \bmod(2t)$.

For the proof of the equations (ii)′, (iii)′, (iv)′ and (v)′, we may use $x^0 = x^{4t} = 1$, $x^{2t} = -1$. The proof is left to the reader.

The inequalities (vi)′ are true because $x, x^2, \cdots, x^{4t}=1$ are all different.

Hence (4.1) satisfies the conditions of Theorem 3. As illustrations two designs follow.

Set of generators of mixed tournaments for $v = 4t+1 = p$ and $s = 1$

v Generators

13 $(1, 2^{(a)}, 12, 11^{(a)}; 8, 3^{(a)}, 5, 10^{(a)})$, $(2, 4^{(a)}, 11, 9^{(a)}; 3, 6^{(a)}, 10, 7^{(a)})$, $(4, 8^{(a)}, 9, 5^{(a)}; 6, 12^{(a)}, 7, 1^{(a)})$

17 $(1, 3^{(a)}, 16, 14^{(a)}; 13, 5^{(a)}, 4, 12^{(a)})$, $(3, 9^{(a)}, 14, 8^{(a)}; 5, 15^{(a)}, 12, 2^{(a)})$, $(9, 10^{(a)}, 8, 7^{(a)}; 15, 11^{(a)}, 2, 6^{(a)})$, $(10, 13^{(a)}, 7, 4^{(a)}; 11, 16^{(a)}, 6, 1^{(a)})$.

An alternate development of the designs of this section is possible by sets of generators for v in the forms $6t \pm 1$. The generators of these forms of v are

$$G'_{j'} = (x^{j'+0}, x^{j'+1}, x^{j'+3t}, x^{j'+3t+1}; x^{j'+(3t/2)}, x^{j'+(3t/2)+1}, x^{j'+(9t/2)}, x^{j'+(9t/2)+1})$$
$$j' = 0, 1, \cdots, (3t/2) - 1, \quad \text{for } v = 6t + 1$$

$$G'_{j'} = (x^{j'+0}, x^{j'+1}, x^{j'+3t-1}, x^{j'+3t}; x^{j'+(3t-1)/2}, x^{j'+(3t+1)/2}, x^{j'+(9t-3)/2}, x^{j'+(9t-1)/2})$$
$$j' = 0, 1, \cdots, (3t - 3)/2, \quad \text{for } v = 6t - 1.$$

The proof that these generators satisfy the conditions of Theorem 3 is similar to the proof for the generators of this section. This alternate method gives all the solutions of Section 4 except $v = 3^n$.

5. In this section the theorems of Sections 2 and 4 will be generalized as follows.

GENERALIZED THEOREM 1. *A mixed tournament for $v = 4t+1 = p^n$ and s an integer $\geqq 0$ (where p denotes an odd prime and n an integer $\geqq 1$), when generated by*

a set of $(2t/2^{s+1})$ *generators* $G_0, G_1, \cdots, G_{(2t/2^{s+1})-1}$, *in the manner prescribed either in Section* 2 *or* 4, *satisfies* I *if and only if:*

(i) *no two of the* $2^s \cdot t$ MM_t *differences (except* $s=0$) *are equal,*

(ii) *no two of the* $2^s \cdot t$ WW_t *differences (except* $s=0$) *are equal,*

(iii) *the* MW_t *differences are in* $4t$ *distinct sets of* 2^s *equal differences except* $s=0$ *where no two differences are equal,*

(iv) *the* MW_0 *differences are in* $4t$ *distinct sets of* 2^s *equal differences except* $s=0$ *where no two differences are equal,*

(v) *the* MM_0 *differences are in* $2t$ *distinct sets of* 2^s *equal differences except* $s=0$ *where no two differences are equal,*

(vi) *the* WW_0 *differences are in* $2t$ *distinct sets of* 2^s *equal differences except* $s=0$ *where no two differences are equal,*

(vii) *none of the* MM_t, MM_0, WW_t, WW_0, MW_t *and* MW_0 *differences is zero.*

REMARK. The theorems of Sections 2 and 4 can also be generalized in a similar manner for $v=6t\pm 1=p^n$ and s any integer $\geqq 1$.

Acknowledgement. I am grateful to the referee for his helpful suggestions in improving the earlier version of this paper.

PRIME SEMIGROUPS AND SEMIRINGS

AZRIEL ROSENFELD, University of Maryland

1. Introduction. A group has no proper subgroups if and only if it is trivial or cyclic of prime order, i.e. isomorphic to the additive group of integers modulo 1 or modulo a prime p. We shall refer to such a group as a *prime group*. A field has no proper subfields if and only if it is isomorphic to the field of rational numbers or to the field of integers modulo a prime p; these fields are called the *prime fields*. The purpose of this note is to generalize these well-known results by characterizing the semigroups and semirings which have no proper subsemigroups or subsemirings.

2. Prime semigroups. We call a semigroup (=a set closed under an associative composition) *prime* if it has only the empty set, trivial (=one-element) sets, and itself as subsemigroups. (By allowing trivial subsemigroups, we make it possible for a nontrivial group to be a prime semigroup, even though it has the trivial subgroup $\{e\}$.)

Our main result about prime semigroups is

THEOREM 1. *A semigroup is prime if and only if it is a prime group or has at most two elements.*

Proof. If S has at most two elements, it has only the empty set, trivial sets, and itself as subsets, and so is certainly prime. If S is a prime group, it is finite so that any nonempty subsemigroup S' of S is a finite cancellation semigroup, hence a group; thus since S is prime, S' must be $\{e\}$ or S, making S a prime semigroup. Conversely, if S is a group and a prime semigroup, it is certainly a prime group. It thus remains only to show that if S is a prime semigroup and not a group, it can have at most two elements. We prove this by considering several possible cases:

(a) If S has both left and right absorbent elements, it has a unique two-sided absorbent element a, and can have no other left or right absorbent element. Hence $\{a\}$ is the only trivial left or right ideal of S. Since a left or right ideal is a subsemigroup, we thus have $xS=\{a\}$ or S, and $Sx=\{a\}$ or S, for all $x\in S$.

(a1) If $xS=Sx=\{a\}$ for all x, the composition on S is defined by $xy=a$ for all $x, y\in S$; but for this composition any subset containing a is a subsemigroup, so that S can have at most two elements.

(a2) Otherwise, there exists $b\in S$, evidently $\neq a$, such that (say) $Sb=S$. (The proof if there exists b such that $bS=S$ is exactly analogous.) In particular, there exists $e\in S$, $\neq a$ such that $eb=b$. Now $\{x \mid x\in S; ex=x\}$ is a right ideal and contains a and b, so cannot be trivial; hence it must be all of S, making e a left identity. Furthermore, for all $y\neq a\in S$, Sy is a left ideal and contains $ey=y$, so cannot be trivial and must be all of S; thus there exists $y'\in S$ such that $y'y=e$. It follows readily that $S-\{a\}$ is a subgroup of S; hence this subgroup must be trivial, so that S has just two elements.

(b) Suppose now that S has no right absorbent elements (the proof if it has no left absorbent elements is exactly analogous). Then S has no trivial left ideals, so that $Sx=S$ for all $x\in S$, and in particular, for any $x\in S$ there exists $e_x\in S$ such that $e_xx=x$.

(b1) If S has an element z which is not left absorbent, $\{z\}$ cannot be a right ideal; hence the right ideal $\{w \mid w\in S; e_zw=w\}$, which contains z, must be all of S, making e_z a left identity. Moreover, for all $x\in S$ we have $Sx=S$, so that there exists $x'\in S$ such that $x'x=e_z$, and S is a group, contradiction.

(b2) Hence every element of S is left absorbent, so that the composition on S is defined by $xy=x$ for all $x, y\in S$; but for this composition, any subset is a subsemigroup, so that S can have at most two elements.

A shorter proof of Theorem 1 can be given along the following lines:

If every element of S is idempotent, it is not difficult to show that S has at most two elements. If $x\in S$ is not idempotent, the nontrivial subsemigroup (x) generated by x must be all of S. If all the powers of x are distinct, (x^2) is a nontrivial proper subsemigroup; let m be the smallest positive integer such that $x^m=x^r$ for some $r>m$. If $r=m+1$, then $x^s=x^m$ for all $s>m$ and $\{x^{m-1}, x^m\}$ is a nontrivial subsemigroup, so that S has at most two elements. Otherwise, readily

$\{x^m, \cdots, x^{r-1}\}$ is a nontrivial subsemigroup, so that we must have $m=1$; in this case it is easy to show that S must be a cyclic group of prime order.

The proof given above, though somewhat longer, is needed as a basis for proving Theorem 2. (I am indebted to the referee for suggesting that an outline of the shorter proof of Theorem 1 be included.)

COROLLARY. *A semigroup has no subsemigroups other than itself and $\varnothing$ if and only if it is trivial.*

Proof. If S is nontrivial, cases (a) cannot hold, since if S had an absorbent element, $\{a\}$ would be a subsemigroup; case (b1) cannot hold, since if S were a group, $\{e\}$ would be a subsemigroup; and case (b2) cannot hold, since $\{x\}$ would be a subsemigroup for each $x \in S$.

Note that in the course of proving Theorem 1 we have established

PROPOSITION *1. The semigroup S has no proper, nontrivial left or right ideals if and only if one of the following is true:*

(a) *S is a group,*

(b) *S has an absorbent element a, and $S-\{a\}$ is a group,*

(c) *S has at most two elements.*

Proof. By the proof of Theorem 1, if S has no proper nontrivial left or right ideals, one of the following must hold:

(a) S is a group (Case b1). In this case, $\varnothing$ and S are the only ideals.

(b) $S-\{a\}$ is a group, where a is absorbent (Case a2). In this case the ideals are $\varnothing$, $\{a\}$ and S.

(c1) $xy=a$ for all $x, y \in S$, where a is absorbent (Case a1). In this case any subset containing a is a two-sided ideal, so that S can have at most two elements.

(c2) $xy=x$ for all $x, y \in S$, or $xy=y$ for all $x, y \in S$ (Cases b2). In the former case any subset is a right ideal, in the latter case a left ideal, so that S can have at most two elements.

COROLLARY. *A semigroup has no proper left or right ideals if and only if it is a group or empty.*

3. Prime semirings. By a *semiring* we mean a set closed under two compositions, $+$ and $\cdot$, where $+$ is associative and commutative; $\cdot$ is associative; and $\cdot$ distributes over $+$. We call a semiring *prime* if it has only the empty set, trivial sets, and itself as subsemirings. (Here again, by allowing trivial subsemirings, we make it possible for a nontrivial ring to be a prime semiring even though it has the trivial subring $\{0\}$.)

LEMMA. *A multiplicatively absorbent element of a semiring is additively idempotent.*

Proof. An absorbent element 0 must be unique; but for all x we have $x(0+0) = x0+x0 = 0+0$ and $(0+0)x = 0x+0x = 0+0$, so that $0+0$ is also absorbent and so must be the same as 0.

THEOREM 2. *A semiring is prime if and only if its additive semigroup is prime.*

Proof. Since a subsemiring is an additive subsemigroup, "if" is clear. To prove "only if," we again consider various possible cases:

(a) If S has a unique multiplicatively absorbent element 0, then as in the proof of Theorem 1, the only trivial left or right ideal of S is $\{0\}$ (it is an ideal since by the Lemma 0 is additively idempotent). Hence if S is prime, we have $xS=\{0\}$ or S, and $Sx=\{0\}$ or S, for all $x\in S$.

(a1) If $xS=Sx=\{0\}$ for all $x\in S$, the multiplicative composition on S is defined by $xy=0$ for all $x, y\in S$. For this composition, a nonempty subset of S is a subsemiring if and only if it contains 0 and is an additive subsemigroup. Thus if every additive subsemigroup of S contains 0, the Theorem is proved. If not, 0 must fail to be in some monogenic additive subsemigroup $A=\{na \mid n\in Z^+\}$, $a\in S$. Hence the sup of A and $\{0\}$ in the lattice of additive subsemigroups must be all of S. But readily this sup is $A\cup\{0\}\cup\{na+0 \mid n\in Z^+\}=A\cup\{0\}\cup(A+\{0\})$, and this has $\{0\}\cup(A+\{0\})$ as a subsemiring (since it is an additive subsemigroup and contains 0); hence this subsemiring must be $\{0\}$ or all of S.

(a1.1) If $A+\{0\}=\{0\}$, we have $A\cup\{0\}=S$, and if A' is any subsemigroup of A, then $A'\cup\{0\}$ is a subsemiring of S. Hence for S to be prime, A can have no subsemigroups but itself and $\varnothing$, which implies (Corollary to Theorem 1) that $A=\{a\}$ is trivial, so that $S=\{0, a\}$.

(a1.2) If $(A+\{0\})\cup\{0\}=S$, and $0\notin A+\{0\}$, we can apply the argument of (a1.1) to $A+\{0\}$ to prove it trivial, so that $S=\{0, a+0\}$.

(a1.3) Otherwise, we have $A+\{0\}=S$, so that $0\in A+\{0\}$, say $0=ma+0$; but then $S=\{a+0, 2a+0, \cdots, (m-1)a+0, 0\}$ is an additive group with identity 0, and since it can have no proper subsemigroups which contain 0, in particular it can have no proper subgroups, making it a prime group.

(a2) If (a1) does not hold, then just as in the proof of Theorem 1, $S-\{0\}$ is a multiplicative group. Let its identity be 1; then $\{n1 \mid n\in Z^+\}$ is a subsemiring, so is trivial ($=\{1\}$) or is all of S.

(a2.1) If $\{n1\}$ is trivial, 1 is additively idempotent, so that $\{0, 1+0\}$ is a subsemiring. Hence if $1+0\neq 0$ we must have $S=\{0, 1+0\}$, while if $1+0=0$, then $\{0, 1\}$ is a subsemiring, so that in any case $S=\{0, 1\}$.

(a2.2) But if $\{n1\}=S$, note that any additive subsemigroup of $\{n1\}$ is an ideal, so that the additive semigroup $\{n1\}$ must be prime.

(b) If (a) does not hold, then just as in the proof of Theorem 1, either (b1) or (b2) must hold:

(b1) S is a multiplicative group, say with identity 1, and as in case (a2), we have $\{n1\}=\{1\}$ or S.

(b1.1) If $\{n1\}=\{1\}$, every element of S is additively idempotent (indeed, $x+x=x1+x1=x(1+1)=x1=x$ for all $x\in S$), but no $x\neq 1$ can be multiplicatively idempotent, so that for any $a\neq 1$ the subsemiring generated by either a or a^{-1} is all of S. Readily, for a^{-1} this subsemiring is

$$\left\{\sum_{i=1}^{k}\delta_i a^{-i} \;\middle|\; k\in Z^+;\ \delta_i=0 \text{ or } 1,\ 1\leqq i\leqq k\right\},$$

and since 1 must be in it, we have $1=\sum_{i=1}^{n}\delta_i a^{-i}$ for some $n\in Z^+$ and some choice of δ's. Hence $a^n=\sum_{i=1}^{n}\delta_i a^{n-i}$ is a sum of lower (nonnegative) powers of a, so that any power of a is such a sum, and since a generates S, we have $S=\{\sum_{i=0}^{n}\delta_i a^i \mid \delta_i=0 \text{ or } 1,\ 1\leqq i\leqq n\}$. It follows that $b=\sum_{i=0}^{n}a^i$ is additively absorbent. But then for all $x, y\in S$ we have

$$x+y=xy^{-1}bb^{-1}y+bb^{-1}y=(xy^{-1}b+b)b^{-1}y=(b)b^{-1}y=y,$$

so that any $y\in S$ is additively absorbent, and since an absorbent element must be unique, S is trivial.

(b1.2) If $\{n1\}=S$, then as in case (a2.2), the additive semigroup of S must be prime. [Note, however, that in this case if S is nontrivial, 1 is not additively idempotent, so that as in the first part of case (b1.1), no element of S can be additively idempotent. But if the additive semigroup of S is prime, it is finite, hence does contain an idempotent (see [1]). Thus this case cannot arise unless S is trivial.]

(b2) The composition on S is given by $xy=x$ (or by $xy=y$) for all $x, y\in S$. In this case any subset is a multiplicative subsemigroup, so that any additive subsemigroup is a subsemiring; hence the additive semigroup of S must be prime. [Note, however, that in this case, if S has more than two elements, its additive semigroup is a prime group $\{0, a, \cdots, (p-1)a\}$, and since $(ma)(na)=(mn)a=(na)(ma)$, the multiplicative composition on S must be commutative, so that $x=xy=yx=y$ for all $x, y\in S$, making S trivial, contradiction. Hence this case cannot arise if S has more than two elements.]

Using Theorem 2 we can immediately prove

THEOREM 3. *The semiring S is prime if and only if one of the following is true:*

(1) *S has at most two elements,*

(2) *S is isomorphic to the zero-ring whose additive group is the additive group of integers modulo a prime p,*

(3) *S is isomorphic to the field of integers modulo a prime p.*

Proof: Each of (1—3) is a prime additive semigroup, so that "if" is assured. Conversely, by Theorems 1 and 2, if S is prime it either has at most two elements, or its additive semigroup is a prime group. Moreover, if S has more than two elements, one of cases (a1.3) or (a2.2) of Theorem 2 must hold. In the former case, S is a zero-ring; while in the latter case, $S-\{0\}$ is a multiplicative group, so that S is a division ring, and readily must be isomorphic to a field of integers modulo p.

We also have

PROPOSITION 2. *A ring has no proper left or right ideals if and only if it is a division ring or is isomorphic to the zero-ring whose additive group is the integers modulo p, where $p=1$ or is prime.*

Proof. Since a ring R has a multiplicatively absorbent element 0, case (b) of Theorem 2 cannot arise. In case (a1), R is a zero-ring, and in case (a2) $R-\{0\}$ is a multiplicative group, so that R is a division ring. Moreover, in case (a1) any

additive subgroup of R is an ideal (since it contains 0), so that the additive group of R must be prime. Conversely, if the additive group is prime, there are no proper subgroups and *a fortiori* no proper left or right ideals; and as is well known, a division ring can have no proper left or right ideals.

COROLLARY. *A ring has no proper subrings if and only if it is a prime semiring.*

Proof. If R has no proper subrings, it has no proper left or right ideals, so that by the Proposition it is a prime semiring (case (2) of Theorem 3) or a division ring. But in the latter case it must be a prime field, and it cannot be the field of rational numbers since this has proper subrings; hence it is a prime semiring (case (3) of Theorem 3) in this case too.

ON GROUPS, QUASI- AND OTHERWISE

T. S. FRANK, Le Moyne College

1. Introduction. It is traditional, whenever the group concept is discussed for the first time, to drag forth as examples the familiar numerical sets and their operations. The integers under addition, the nonzero rational numbers under multiplication, and so forth are customarily given as examples of systems which satisfy the group axioms, while modifications of these, e.g. the integers under multiplication, serve as bad examples, that is systems which do not quite satisfy the group axioms. Other examples can be obtained by constructing from one of the familiar groups $(G, \cdot)$ a system $(G, \circ)$, where the operation is defined by: $a \circ b = a \cdot b^{-1}$. The integers under subtraction, the nonzero rationals under division, etc. are examples of such systems. But the operation is usually so poorly behaved (only the closure axiom holds in general) that any further discussion of such systems is usually abandoned.

Thus if we replace the group operation by its inverse, we do not in general any longer have a group. In fact it is an easy consequence of the group axioms that a necessary and sufficient condition that such a system again be a group is that every element in the original group be of order 2. The question remains, however: For the other groups, how poorly behaved and how weak is the structure formed when the operations of these groups are replaced by their inverse operations?

The degree to which these systems are "nongroups" is investigated in the present paper by considering certain quasigroups, of which these systems are examples. Although there are many ways of measuring the degree to which a

given system resembles or fails to resemble a group, the approach taken here is that of mapping the system homomorphically into a group and then examining the kernel of this homomorphism. Intuitively, the smaller the kernel the more grouplike the system is. In view of the preceding paragraph it should not be surprising that the group most closely resembled (in the present sense) by a system of this sort is one in which each element is of order 2. Further, we shall see that this group is easily constructible.

2. Preliminaries.

DEFINITION. *By an inversive quasigroup* $(Q, \circ)$ *is meant a nonempty set* Q *along with a closed, single-valued binary operation* $\circ$ *on* Q, *satisfying the following axioms*:

(1) *For* $a, b \in Q$ *there is a unique* $d \in Q$ *such that* $d \circ a = b$;

(2) *For any* $c \in Q$ *there is* c' *in* Q *such that for each* $a \in Q$, $(a \circ c) \circ c' = a$. (*This element* c' *is called a pseudo-inverse for* c.)

Example. As mentioned in the introduction we have a convenient class of examples of inversive quasigroups. Let $(G, \cdot)$ be a group, and construct a quasigroup $(G, \circ)$ by defining $a \circ b = a \cdot b^{-1}$. It is easy to see that $d \circ a = b$ is solved by taking $d = b \cdot a$, and that c^{-1} will play the role of a pseudo-inverse c' for c.

REMARK. Although the inversive quasigroups constructed in the example above form a large class, it is not difficult to give examples of inversive quasigroups which cannot be so constructed from groups.

The following useful theorems are immediate consequences of the definition.

THEOREM 1. *Every inversive quasigroup has right cancellation.*

THEOREM 2. *If* c' *is a pseudo-inverse for* c, *then* c *is a pseudo-inverse for* c'.

THEOREM 3. *If* c' *and* c'' *are pseudo-inverses for* c, *then for any* $a \in Q$, $a \circ c' = a \circ c''$.

4. Homomorphisms.

DEFINITION. *A homomorphism from an inversive quasigroup* $(Q, \circ)$ *to a group* $(G, \cdot)$ *is a mapping* h *from* Q *to* G *such that for each* $a, b \in Q$, $h(a \circ b) = h(a) \cdot h(b)$. *The kernel* K_h *of* h *is* $\{x \in Q : h(x) = \text{identity of } (G, \cdot)\}$.

DEFINITION. *The nucleus* $N(Q)$ *of a quasigroup* $(Q, \circ)$ *is* $\{x \circ x' : x \in Q\}$.

It follows from Theorem 3 that each product $x \circ x'$ in $N(Q)$ is uniquely defined, although the pseudo-inverse x' may not be. Further, from Theorem 2, $N(Q) = \{x' \circ x : x \in Q\}$.

THEOREM 4. *If* h *is a homomorphism from a quasigroup* $(Q, \circ)$ *to a group* $(G, \cdot)$, *then* $(K_h, \circ)$ *is an inversive sub-quasigroup of* $(Q, \circ)$.

The proof is straightforward and will not be included.

DEFINITION. *For any ordered triple* (a, b, c) *of elements of* Q *there is, by solvabil-*

ity of equations in $(Q, \circ)$, *an element* $x \in Q$ *such that* $a \circ (b \circ c) = x \circ [(a \circ b) \circ c]$. *The element* x *is called an associator and is denoted* $\langle abc \rangle$. *The set of all associators of* $(Q, \circ)$ *is denoted* $A(Q)$.

THEOREM 5. *If* h *is a homomorphism from an inversive quasigroup* $(Q, \circ)$ *to a group* $(G, \cdot)$, *then* $N(Q) \cup A(Q) \subseteq K_h$.

Proof. Let e be the identity of $(G, \cdot)$. Then it is immediate that $h(x \circ x') = e$ for any $x \in Q$. Furthermore, applying h to both sides of the equation $a \circ (b \circ c) = \langle abc \rangle \circ [(a \circ b) \circ c]$, we obtain

$$h(a) \cdot h(b) \cdot h(c) = h(\langle abc \rangle) \cdot h(a) \cdot h(b) \cdot h(c), \quad \text{so} \quad h(\langle abc \rangle) = e.$$

DEFINITION. *A subset* S *of* Q *is said to partition the quasigroup* $(Q, \circ)$ *if ana only if:* (1) *For any* $a, b \in Q$, *the sets* $S \circ a$ *and* $S \circ b$ *are either identical or disjoint, and* (2) *if* $x \in S \circ a$ *and* $y \in S \circ b$, *then* $x \circ y \in S \circ (a \circ b)$.

THEOREM 6. *Let* h *be a homomorphism from* $(Q, \circ)$ *to* $(G, \cdot)$. *Then* K_h *partitions* $(Q, \circ)$.

Proof. Denoting K_h simply by K and letting e be the identity of $(G, \cdot)$, we suppose first that for some $a, b \in Q$, $K \circ a \cap K \circ b \neq \varnothing$. Then there are $k_1, k_2 \in K$ such that $k_1 \circ a = k_2 \circ b$. Hence $h(a) = h(k_1 \circ a) = h(k_2 \circ b) = h(b)$. Now

$$(K \circ b) \circ a' = K, \text{ for } h[(K \circ b) \circ a'] = h(K) \cdot h(b) \cdot h(a') = h(b) \cdot h(a)^{-1} = e.$$

Thus $(K \circ b) \circ a' \subseteq K$ which, by left-solvability implies $(K \circ b) \circ a' = K$. By Theorem 2, $K \circ b = K \circ a$. Thus the first condition of the preceding definition is satisfied. Next assume $x \in K \circ a$, $y \in K \circ b$. Then $h(x) = h(a)$, $h(y) = h(b)$, so $h(a \circ b) = h(x \circ y)$. Thus $(x \circ y) \circ (a \circ b)' \in K$, or equivalently, $x \circ y \in K \circ (a \circ b)$.

DEFINITION. *Let* Σ *denote the intersection of all inversive sub-quasigroups of* $(Q, \circ)$ *which partition* $(Q, \circ)$ *and contain* $N(Q) \cup A(Q)$.

Now since the kernel of any homomorphism from $(Q, \circ)$ into any group must contain $(\Sigma, \circ)$ as an inversive sub-quasigroup, Σ is the smallest possible candidate for the kernel of a homomorphism. The next two theorems show that there is a homomorphism of $(Q, \circ)$ into a group with Σ as its kernel.

THEOREM 7. *The collection* $\{\Sigma \circ a : a \in Q\}$ *of right-translates of* Σ *form a group under the operation:* $\Sigma \circ a \sim \Sigma \circ b = \Sigma \circ (a \circ b)$.

Proof. (1) The operation is well-defined, since Σ partitions $(Q, \circ)$. For if $\Sigma \circ a_1 = \Sigma \circ a_2$, and $\Sigma \circ b_1 = \Sigma \circ b_2$, then $a_2 \in \Sigma \circ a_1$ and $b_2 \in \Sigma \circ b_1$, so $a_2 \circ b_2 \in \Sigma \circ (a_1 \circ b_1)$. But since $a_2 \circ b_2 \in \Sigma \circ (a_2 \circ b_2)$, we have $\Sigma \circ (a_1 \circ b_1) = \Sigma \circ (a_2 \circ b_2)$.

(2) Σ is a left identity. For any $a \in Q$, $a \circ a' \in \Sigma$, so $\Sigma \circ (a \circ a') = \Sigma$. But then

$$\Sigma \sim \Sigma \circ a = \Sigma \circ (a \circ a') \sim \Sigma \circ a = \Sigma \circ [(a \circ a') \circ a] = \Sigma \circ a.$$

(3) The operation is associative, for since $\langle abc \rangle \in \Sigma$, $\Sigma = \Sigma \circ \langle abc \rangle$. Thus

$$(\Sigma \circ a \sim \Sigma \circ b) \sim \Sigma \circ c = \Sigma \circ \langle abc\rangle \sim [(\Sigma \circ a \sim \Sigma \circ b) \sim \Sigma \circ c]$$
$$= \Sigma \circ [\langle abc\rangle \circ [(a \circ b) \circ c]] = \Sigma \circ [a \circ (b \circ c)]$$
$$= \Sigma \circ a \sim (\Sigma \circ b \sim \Sigma \circ c).$$

(4) $\Sigma \circ a'$ is a left inverse for $\Sigma \circ a$.

The group constructed in the preceding theorem will be denoted $(\Gamma, \sim)$.

THEOREM 8. *There is a homomorphism γ from $(Q, \circ)$ to $(\Gamma, \sim)$ such that $K_\gamma = \Sigma$.*

Proof. We need only take $\gamma(a) = \Sigma \circ a$ and observe that $\gamma(a \circ b) = \Sigma \circ (a \circ b) = \Sigma \circ a \sim \Sigma \circ b = \gamma(a) \sim \gamma(b)$.

This group $(\Gamma, \sim)$ is then the group most closely resembled by $(Q, \circ)$ (in this particular homomorphism sense) and Σ, as a subset of Q, gives us a measure of the degree to which $(Q, \circ)$ is grouplike.

5. The special case. We return now to the topic mentioned in the introduction, namely inversive quasigroups constructed from groups. If we begin with a group $(G, \cdot)$ and construct from it the quasigroup $(G, \circ)$ by letting $a \circ b = a \cdot b^{-1}$, then as we have seen the inversive sub-quasigroup $(\Sigma, \circ)$ is the smallest which partitions $(G, \circ)$ and contains $N(Q) \cup A(Q)$. The group $(\Gamma, \sim)$ was seen to be

$$\{\Sigma \circ a : a \in G, \Sigma \circ a \sim \Sigma \circ b = \Sigma \circ (a \circ b)\}.$$

In terms of the operation of $(G, \cdot)$ this is the group

$$\{\Sigma \cdot a : a \in G, Z \cdot a \sim \Sigma \cdot b = \Sigma \cdot b^{-1} \cdot a\}.$$

The following lemma, which seems to be not particularly well known, is of some use in the proof of Theorem 9.

LEMMA. *Let S be a nonempty subset of a group, with the property that any two right-translates of S either coincide or are disjoint. Then S is a coset of some subgroup.*

Proof. Without loss of generality we can assume that the group identity e is in S. Then an element a is in S if and only if $Sa = S$. (We are denoting the group operation here by juxtaposition.) For if $a \in S$, then $a \in Sa$ since $e \in S$. The condition in the statement of the lemma then insures that $Sa = S$. Conversely, if $Sa = S$, then since $a \in Sa$, $a \in S$. Now let $x, y \in S$. Then $S = Sx = Sy$, or $S = Sxy^{-1}$. Hence $xy^{-1} \in S$, so S is a subgroup.

THEOREM 9. *$(\Sigma, \cdot)$ is the normal subgroup of $(G, \cdot)$ generated by the squares and commutators of $(G, \cdot)$.*

Proof. That $(\Sigma, \cdot)$ is a subgroup follows from the lemma and the fact that the identity of $(G, \cdot)$ is in Σ. Now since $A(G) \subseteq \Sigma$, the associator $\langle xyz\rangle \in \Sigma$. It is a computational exercise to show that this element is of the form $x \cdot z \cdot y^{-1} \cdot x \cdot y^{-1} \cdot z^{-1}$. With $y = x$ this becomes the commutator element $x \cdot z \cdot x^{-1} \cdot z^{-1}$, while

letting $y=z=$identity of $(G, \cdot)$ we obtain the square x^2. Conversely the associator $x\cdot z\cdot y^{-1}\cdot x\cdot y^{-1}\cdot z^{-1}$ can be written in the form

$$[x\cdot z\cdot y^{-1}\cdot x^{-1}\cdot y\cdot z^{-1}]\cdot[z\cdot y^{-1}\cdot x^2\cdot y\cdot z^{-1}\cdot x^{-2}]\cdot[x^2]\cdot[z^2]\cdot[z^{-1}\cdot y^{-1}]^2\cdot[y\cdot z\cdot y^{-1}\cdot z^{-1}].$$

Since each term in brackets is either a square or a commutator, the proof will be complete as soon as Σ is shown to be normal. To establish normality, let $b\cdot\sigma\in b\cdot\Sigma$. Now $b\in\Sigma\circ b$ and $\sigma^{-1}\in\Sigma\circ\sigma^{-1}$, so $b\cdot\sigma=b\circ\sigma^{-1}\in\Sigma\circ(b\circ\sigma^{-1})=\Sigma\cdot\sigma^{-1}\cdot b^{-1}$ $=\Sigma\cdot b^{-1}=\Sigma\cdot b^2\cdot b^{-1}=\Sigma\cdot b$. Hence $b\cdot\Sigma\subseteq\Sigma\cdot b$, the reverse inclusion follows similarly, and $(\Sigma, \cdot)$ is normal in $(G, \cdot)$.

THEOREM 10. $(\Gamma, \sim)\cong(G, \cdot)/(\Sigma, \cdot)$.

Proof. As mentioned above, $(\Gamma, \sim)=\{\Sigma\cdot a\colon a\in G,\ \Sigma\cdot a\sim\Sigma\cdot b=\Sigma\cdot b^{-1}\cdot a\}$. But $\Sigma\cdot b^{-1}\cdot a=\Sigma\cdot(a\cdot b\cdot a^{-1}\cdot b^{-1})\cdot b^2\cdot b^{-1}\cdot a=\Sigma\cdot a\cdot b$. Thus $(\Gamma, \sim)=\{\Sigma\cdot a\colon a\in G,$ $\Sigma\cdot a\sim\Sigma\cdot b=\Sigma\cdot a\cdot b\}$.

We can now sum up the past few results in

THEOREM 11. *If $(G, \circ)$ is the inversive quasigroup constructed from the group $(G, \cdot)$, then the group most closely resembling $(G, \circ)$ is $(G, \cdot)/(\Sigma, \cdot)$.*

REMARK. Since Σ contains the squares of $(G, \cdot)$, the elements of $(\Gamma, \sim)$ are of order 2. In the event $(G, \cdot)$ is abelian, the situation is particularly nice. For then $(\Sigma, \cdot)$ reduces to the subgroup of squares of $(G, \cdot)$. Thus the inversive quasigroup of integers under the operation of subtraction is most like the group of integers modulo 2, while the rationals under the operation of subtraction is completely nongrouplike (since every rational is a "square," more accurately a double). As perhaps a more interesting example, a rather tedious calculation shows that the quasigroup constructed from the group of symmetries of the square most closely resembles the Klein four-group.

Portions of the material presented here are taken from the author's doctoral dissertation at Syracuse University, directed by Professor Walter R. Baum.

ON THE GROUP OF LINEAR TRANSFORMATIONS LEAVING A POLYNOMIAL INVARIANT

L. FLATTO, Belfer Graduate School of Science and B. GROSS, Rutgers, The State University

1. It is well known that with every nonsingular quadratic form $Q(x)$ in n-variables with coefficients from a given field F, one may associate the group $O(n)$ of linear transformations leaving the polynomial invariant. The question naturally arises of characterizing those groups of linear transformations leaving invariant other polynomials. For the case $n=2$, we will show that with certain specified exceptions, the groups are finite. We obtain bounds for the order of these groups. The bounds depend on the order of the polynomial. If F is re-

stricted to be the real field R or the complex field C, then we can describe the structure of the various groups which may arise. That the groups are in general finite is mentioned in Burnside's book ([1] pp. 369–371), but no clear proof is indicated. For $n>2$ the complexity of the problem is much greater. As shown in 3 the case $n=3$ and F the complex field is closely related to a theorem of Hurwitz [3] concerning the group of conformal maps of compact Riemann Surfaces. For arbitrary n and F it is difficult to obtain any general insight and we limit our discussion to the polynomials $\sum_{i=1}^{n} x_i^k$ $(k>2)$, in which case the problem is completely solved.

Since for finite fields it is possible for two distinct polynomials $P_1(x)$ and $P_2(x)$ to have the property that $P_1(a)=P_2(a)$ for all $a\in F$, there is some ambiguity attached to the statement $P(Tx)=P(x)$. We therefore specify that $P(Tx)=P(x)$ shall mean that the two polynomials are identical as polynomials.

2. We state two preliminary lemmas. Both of these are known, but we include the proofs for the sake of completeness.

LEMMA 1. *Suppose T is a linear transformation leaving P invariant, i.e., $P(Tx)=P(x)$. Let*

$$H(x) = \det\left(\frac{\partial^2 P}{\partial x_i \partial x_j}\right).$$

Then $H(x)=(\det T)^2 H(Tx)$.

Proof. Let $T=(a_{ij})$ so that $x'=Tx$ becomes $x_i' = \sum_{j=1}^{n} a_{ij}x_j$, $(1\leqq i\leqq n)$. Differentiating $P(Tx)=P(x)$ twice we obtain

$$\frac{\partial^2 P}{\partial x_i \partial x_j} = \sum_{k=1}^{n}\sum_{l=1}^{n} \frac{\partial^2 P}{\partial x_k' \partial x_l'} \frac{\partial x_k'}{\partial x_i} \frac{\partial x_l}{\partial x_j} = \sum_{k=1}^{n}\sum_{l=1}^{n} \frac{\partial^2 P}{\partial x_k' \mu x_l'} a_{lj}a_{ki},$$

so that $(\partial^2 P/\partial x_i \partial x_j) = (a_{ij})'(\partial^2 P/\partial x_i' \partial x_j')(a_{ij})$, where $(a_{ij})'$ denotes the transpose of (a_{ij}). Thus $H(x)=(\det T)^2 H(Tx)$.

LEMMA 2. *Let $x_i y_i$ $(1\leqq i\leqq 3)$ be two-dimensional vectors over the field F. Suppose that any two of the x_i's and any two of the y_i's are linearly independent. Then there exists a linear transformation T (necessarily nonsingular), such that $Tx_i=\lambda_i y_i$ where $\lambda_i\neq 0$ $(1\leqq i\leqq 3)$. If T_1 is another such linear transformation, then $T_1=cT$ for some $c\neq 0$.*

REMARK. This is just the algebraic formulation of the fundamental theorem of projective geometry.

Proof. Using x_1, x_2 as basis for the 2-dimensional vector space over F, we have $x_1=(1, 0)$, $x_2=(0, 1)$, $x_3=(a_1, a_2)$ where $a_1a_2\neq 0$ and $y_i'=(b_{i1}, b_{i2})$ $(1\leqq i\leqq 3)$. Since $Tx_i=\lambda_i y_i$ we conclude that

$$T = \begin{pmatrix} \lambda_1 b_{11} & \lambda_2 b_{21} \\ \lambda_1 b_{12} & \lambda_2 b_{22} \end{pmatrix}.$$

Since $Tx_3=\lambda_3 y_3$ we have

$$\lambda_3 b_{31} = a_1 b_{11}\lambda_1 + a_2 b_{21}\lambda_2$$
$$\lambda_3 b_{32} = a_1 b_{12}\lambda_1 + a_2 b_{22}\lambda_2 .$$

Since

$$\begin{vmatrix} a_1 b_{11} & a_2 b_{21} \\ a_1 b_{12} & a_2 b_{22} \end{vmatrix} = a_1 a_2 \begin{vmatrix} b_{11} & b_{21} \\ b_{12} & b_{22} \end{vmatrix} \neq 0$$

we can solve the above system for λ_1, λ_2 and obtain $\lambda_1 = A_1\lambda_3$, $\lambda_2 = A_2\lambda_3$ where A_1, A_2 depend on a_1, a_2, b_{i1}, b_{i2}. A_1, A_2 are different from zero, for otherwise we would read off from (2) that y_3, y_2 or y_3, y_1 are linearly dependent. Since $\lambda_3 \neq 0$ is arbitrarily chosen, we obtain the desired result.

3. We now treat the case $n=2$. Let K denote the algebraic closure of F. Let $P=\sum_{j=0}^{n} P_j$ where P_j is homogeneous of degree j. If G denotes the group of nonsingular transformations leaving P invariant, then $G=\bigcap_{j=1}^{n} G_j$ where G_j denotes the group of nonsingular transformations leaving P_j invariant. We may henceforth assume that P is a homogeneous polynomial. Now

$$P(x) = \prod_{i=1}^{m} L_i^{k_i}(x)$$

where the L_i's are distinct homogeneous linear factors with coefficients from K (we call two linear factors distinct if they are linearly independent). We write

$$L_i(x) = a_i \cdot x, \quad \text{where} \quad a_i = (a_{i1}, a_{i2}), \quad x = (x_1, x_2), \quad a_i \cdot x = a_{i1}x_1 + a_{i2}x_2.$$

Let $k=\deg P$ so that $k=\sum_{i=1}^{m} k_i$. We state the following

THEOREM 3.1. *If $m>2$, then G is a finite group whose order $\leqq k^2(k-1)(k-2)$. If $m=1$ or 2 and F is algebraically closed then G is an infinite group. For $m=1$ G is conjugate to*

$$\left\{\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix} \middle| \, a^{k_1} d^{k_2} = 1\right\}$$

if $k_1 \neq k_2$ and to

$$\left\{\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix} \middle| \, a^{k_1} d^{k_1} = 1\right\} \cup \left\{\begin{pmatrix} 0 & b \\ c & 0 \end{pmatrix} \middle| \, b^{k_1} c^{k_1} = 1\right\}$$

if $k_1 = k_2$.

Proof. Suppose that $m>2$ and that $P(Tx)=P(x)$. It follows from the unique factorization theorem that $a_i \cdot Tx = \lambda_i a_{\sigma(i)} \cdot x$, where $\lambda_i \in K$ and $\neq 0$ and $\sigma(i)$ is a permutation of 1 to m. Let T' denote the transpose of T. Then

$$T'(a_i) = \lambda_i a_{\sigma(i)} \qquad (1 \leqq i \leqq 3) \tag{1}$$

where we have $N=m(m-1)(m-2)$ choices for $\sigma(i)$. It follows from Lemma 2 that for each of the N choices (1) has a solution. Suppose that for exactly m of the choices we can find a solution T such that $P(Tx)=P(x)$ and for each of these pick a T. We label these $T_1, T_2, \cdots, T_m$. By Lemma 2, $T=c_jT_j$ where $c_j\neq 0$ for some j, $(1\leqq j\leqq m)$. Since $P(T_jx)=P(x)$ and $P(Tx)=P(x)$ we conclude $P(x)=c_j^kP(x)$ so that $c_j^k=1$. Thus c_j can take on at most k distinct values and G is finite, its order $\leqq k(m-1)(m-2)\leqq k^2(k-1)(k-2)$.

We consider next the case where $m=1$, 2 and F is algebraically closed (so that $F=K$). By a linear change of variables, we may assume

$$\text{(a) } P=x_1^{k_1} \quad \text{or} \quad \text{(b) } P=x_1^{k_1}x_2^{k_2}.$$

A direct calculation yields in case (a)

$$T=\left\{\begin{pmatrix} a & 0 \\ c & d \end{pmatrix} \middle| \, a^{k_1}=1,\ a\ d\neq 0\right\}.$$

Now $P(x)=0\Rightarrow P(Tx)=0$. In case (b) $P=0$ along the lines $x_1=0$, $x_2=0$ so that T takes these lines into themselves. Thus

$$T=\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}, \quad \text{where} \quad ad\neq 0 \text{ and } a^{k_1}d^{k_2}=1.$$

If $k_1=k_2$ we also have the possibility

$$\begin{pmatrix} 0 & b \\ c & 0 \end{pmatrix} \quad \text{where} \quad bc\neq 0 \text{ and } b^{k_1}c^{k_1}=1.$$

We remark that for $m\geqq 2$, $P(Tx)=P(x)$ implies that T is automatically nonsingular (as two linearly independent a_i's go over into two linear independent a_i's).

If $F=R$ or C we have the following theorem which yields more precise information about the structure of G.

THEOREM 3.2. (a) *Let $F=C$. For $m=1$, 2 G is described as in Theorem* 1. *For $m>2$ let G_0 denote the subgroup of G consisting of the diagonal matrices $\left(\begin{smallmatrix}\lambda & 0\\ 0 & \lambda\end{smallmatrix}\right)$, where $\lambda^k=1$. Then G/G_0 is isomorphic to one of the following groups: the cyclic groups, the dihedral groups, the groups of the regular solids.*

(b) *Let $F=R$. If $m=1$, then G is described as above. If $m=2$, and P factors over R then G is described as above and if P does not factor over R, then G is isomorphic to the full orthogonal group $O(2)$. If $m>2$, G is isomorphic to a cyclic or dihedral group.*

REMARK. One can exhibit polynomials for which each of the above cases is realized.

Proof. The cases $m=1$, 2 follow as in Theorem 3.1. If $F=R$, $m=2$, and P does not factor over R, then $L_1=\alpha\overline{L}_2$ where $\alpha\neq 0$, and $\overline{L}=\bar{a}_1x+\bar{a}_2y$, if $L=a_1x$

$+a_2y$. In this case $P(x)=\alpha Q^{k_1}(x)$ where $Q(x)$ is a positive definite quadratic form. After a linear change of variables $Q=x_1^2+x_2^2$. It is then clear that G is the full orthogonal group.

Let $m>2$. Theorem 3.1 shows that G is a finite group. If $F=R$, then G leaves a positive definite quadratic form invariant ([1], p. 257). After a linear change of variables we may assume that the form is $x_1^2+x_2^2$. Thus G (after the change of variables) consists of orthogonal matrices. It is well known that a finite subgroup of $O(2)$ is either cyclic or dihedral. One sees quite easily that if G is cyclic its order is $\leqq$ the degree of $P(x)$, and if G is dihedral then its order is $\leqq$ twice degree of $P(x)$. If $F=C$ we argue as follows. Let T be represented by

$$\begin{aligned} x_1' &= ax_1 + bx_2 \\ x_2' &= cx_1 + dx_2. \end{aligned}$$

Then we can map G into the group of linear fractional transformation by letting $T\to T'$ where T' is the fractional linear transformation

$$z' = \frac{az+b}{cz+d}.$$

Let G_1 denote the image of G. The kernel of this map is obviously given by G_0 so that $G/G_0\cong G_1$. Now G_1 is a finite group of linear fractional transformations. These groups are known ([2], p. 133) and are precisely those listed in Theorem 3.2.

As mentioned in the introductory paragraph, it is difficult to obtain a general theory for $n>2$ and we obtain results of a fragmentary nature.

If $n=3$ and F is the complex field then we may reason as follows. If $P(x_1, x_2, x_3)$ is an irreducible polynomial and $P(x_1, x_2, x_3)=0$ is free of singularities, then the projective variety $P(x_1, x_2, x_3)=0$ is a compact Riemann Surface. By a theorem of Hurwitz [3] the order of G^* (the group of conformal maps of the surface onto itself) $\leqq 84(g-1)$ provided $g>1$, g denoting the genus of the surface. We may map the group G into G^* in the obvious fashion and, if the kernel of the map is finite, we have a bound on the order of G.

We illustrate these ideas with the following examples. Let

$$P(x) = x_1^k + x_2^k + x_3^k.$$

The genus in this case is given by $g=\frac{1}{2}\sum_{i=1}^{b}(\alpha_i-1)-n+1$ ([2], p. 227) where the α's are the orders of the branch points, n is the number of sheets, and b the number of branch points. These numbers can be computed as follows. The above mentioned surface is identical with the algebraic curve S: $y=(-x^k-1)^{1/k}$. S has k sheets, k branch points at

$$x = \exp\frac{(2j+1)\pi i}{k} \qquad (0 \leqq j \leqq k-1),$$

each branch point being of order k. Thus

$$g = \tfrac{1}{2}k(k-1) - k + 1 = \frac{(k-1)(k-2)}{2}$$

and so for $k>3$, $g>1$. Hence order of $G^* \leqq 84(g-1) = 42k(k-3)$.

We now show that the kernel k of the mapping of G into G^* is the identity so that G is a finite group of order $\leqq 42k(k-3)(k>3)$. Suppose that $T \in K$ so that $TX = \lambda X$ whenever $x_1^k + x_2^k + x_3^k = 0$. Here $X = (x_1, x_2, x_3)$ and $\lambda = \lambda(X)$ is real valued and an eigenvalue of T. Thus $\lambda(X)$ is constant and we may write $\lambda(X) = \lambda$. It is easily checked that the three vectors $(0, 1, -1)$, $(1, 0, -1)$, $(1, 1, [-2]^{1/k})$ are linearly independent and that they lie in the surface $x_1^k + x_2^k + x_3^k = 0$. Thus $TX = \lambda X$ for all X. Since $P(X) = P(TX) = P(\lambda X) = \lambda^k P(X)$ and k is odd, it follows that $\lambda = 1$. Thus K consists of the identity and G is finite, its order $\leqq 42k(k-3)$.

The above results for $P(x) = x_1^k + x_2^k + x_3^k$ $(k>3)$ were worked out to illustrate the general procedure indicated for the case $n=3$ and F the complex field. Actually we obtain for the polynomials $x_1^k + x_2^k + x_3^k$ a stronger result by more elementary methods. We state the following

THEOREM 3.3. *Let* $P(x) = \sum_{i=1}^n x_i^k$ $(k>2)$. *Let* F *be either of infinite characteristic or of finite characteristic* p *where* $p \nmid k(k-1)$. *Let* G *be the set of linear transformations* T *for which* $P(Tx) = P(x)$. *Then* G *is the group of linear transformations* $x_i' = \epsilon_i x_{\sigma(i)}$ *where* $\epsilon_i^k = 1$ $(1 \leqq i \leqq n)$ *and* $\sigma(i)$ *is an arbitrary permutation of* 1 *to* n.

Proof. The transformations $x_i' = \epsilon_i x_{\sigma(i)}$ $(1<i<n)$ clearly belong to G and we show conversely that every transformation is of this form. Let $T = (a_{ij})$ where $x_i' = \sum_{j=1}^n a_{ij}x_j$ $(1 \leqq i \leqq n)$. A direct calculation shows that $H(x) = [k(k-1)]^n x_1^{k-2} \cdots x_n^{k-2}$. Since we assume that $p \nmid k(k-1)$, $H(x) \neq 0$ and it follows from Lemma 2 of section 2 that $\det T \neq 0$. Hence G is a group. Employing again Lemma 2 we obtain

$$x_1^{k-2} \cdots x_n^{k-2} = (\det T)^2 \prod_{i=1}^n \left(\sum_{j=1}^n a_{ij}x_j \right)^{k-2}.$$

It follows from the unique factorization theorem that $x_i' = \lambda_i x_{\sigma(i)}$ where $\lambda_i \in F$ $(1 \leqq i \leqq n)$. Now $P(Tx) = P(x)$ implies that

$$\sum_{i=1}^n x_i^k = \sum_{i=1}^n \lambda_i^k x_{\sigma(i)}^k = \sum_{i=1}^n \lambda_{\sigma^{-1}(i)}^k x_i^k$$

where σ^{-1} is the permutation inverse to σ. Thus $\lambda_{\sigma^{-1}(i)} = 1$ for $1 \leqq i \leqq n$ which means that $\lambda_i^k = 1$ $(1 \leqq i \leqq n)$ and the proof is complete.

UNIQUENESS OF SOLUTIONS OF ORDINARY DIFFERENTIAL EQUATIONS

D. V. V. WEND, Montana State University

Introduction. It is not hard to prove that the initial value problem

$$y' = f(x, y), \qquad y(x_0) = y_0, \tag{1}$$

has a unique solution on some interval containing x_0 if $f(x, y)$ is continuous in both x and y on some rectangle R centered at (x_0, y_0) and non-**increasing** in y for each fixed x on R. (See, for example, [1, p. 384, Theorem 7.5] and [3, p. 34, Corollary 6.3].) The question naturally arises whether (1) has a unique solution if $f(x, y)$ is non-**decreasing** in y. That the answer is "no" in general is shown by the example $y' = y^{2/3}$, $y(0) = 0$, which has the solutions $y(x) \equiv 0$ and $y(x) = x^3/27$. However, we will prove in this note, under suitable restrictions, a "one-sided" uniqueness theorem when $f(x, y)$ is nondecreasing in **both** x *and* y as a special case of a uniqueness theorem for a general nth order initial value problem.

The uniqueness theorem. We prove the uniqueness theorem for the general nth order initial value problem

$$y^{(n)} = f(x, y, y', \cdots, y^{(n-1)}), \; y^{(k)}(0) = y_k, \qquad k = 0, 1, \cdots, n-1 \; (y^{(0)} = y). \tag{2}$$

THEOREM. *Let R be the region defined by the inequalities $0 \leqq x - x_0 < a$, $|s_k - y_k| < b_k$, $k = 0, 1, \cdots, n-1$, where $y_k \geqq 0$ for $k > 0$. Suppose the function $f(x, s_0, s_1, \cdots, s_{n-1})$ in (2) is nonnegative, continuous and nondecreasing in x, and continuous and nondecreasing in s_k for each $k = 0, 1, \cdots, n-1$ in the region R. If in addition*

$$f(x, y_0, \cdots, y_{n-1}) \not\equiv 0 \quad \text{in } R \text{ for } x > x_0, \tag{3}$$

then the initial value problem (2) has at most one solution in R.

Proof. We may assume without loss of generality that $x_0 = 0$ since otherwise a translation would give us this case. Then any solution $y(x)$ of (2) satisfies the integral equation [1, p. 366, Ex. 2]

$$y(x) = \sum_{j=0}^{n-1} \frac{x^j}{j!} y_j + \int_0^x \frac{(x-t)^{n-1}}{(n-1)!} f(t, y(t), \cdots, y^{(n-1)}(t))\, dt,$$

so

$$y^{(k)}(x) = \sum_{j=k}^{n-1} \frac{x^{j-k}}{(j-k)!} y_j + \int_0^x \frac{(x-t)^{n-k-1}}{(n-k-1)!} f(t, y, \cdots, y^{(n-1)})\, dt, \tag{4}$$

$$k = 0, 1, \cdots, n-1,$$

and $y^{(n)}(x) = f(x, y(x), \cdots, y^{(n-1)}(x))$. Condition (3) and the hypotheses that f is nonnegative and $y_k \geqq 0$ for $k > 0$ then imply that $y(x)$ and its first $n-1$ derivatives are strictly increasing functions of x for $x > 0$.

Suppose the solution $y(x)$ is defined in R for $0 \leqq x \leqq b$, $0 < b < a$. Since y and

its derivatives are continuous and increasing, for $\delta>0$ sufficiently small there exists for each $k=0, 1, \cdots, n-1$ a smallest η_k such that $0<\eta_k<b$ and $y^{(k)}(\eta_k)=y_k+\delta$. Let $\eta=\max(\eta_0, \cdots, \eta_{n-1})$ and define $y_\delta(x)=y(x+\eta)$, $0\leqq x\leqq b-\eta$. Then $y_\delta^{(k)}(0)=y^{(k)}(\eta)\geqq y^{(k)}(\eta_k)=y_k+\delta$, and using the hypothesis $f(x, s_0, \cdots, s_{n-1})$ is nondecreasing in x and the fact that $y_\delta^{(n)}(x)=y^{(n)}(x+\eta)=f(x+\eta, y_\delta(x), \cdots, y_\delta^{(n-1)}(x))$, it follows from (4) that

$$y_\delta^{(k)}(x)-y^{(k)}(x)\geqq\delta\sum_{j=k}^{n-1}\frac{x^{j-k}}{(j-k)!}+\int_0^x\frac{(x-t)^{n-k-1}}{(n-k-1)!}\{f(t, y_\delta, \cdots, y_\delta^{(n-1)})-f(t, y, \cdots, y^{(n-1)})\}dt. \tag{5}$$

Since $y_\delta^{(k)}(0)>y^{(k)}(0)$, $y_\delta^{(k)}(x)>y^{(k)}(x)$ for each k for nonnegative x sufficiently close to 0. Suppose $y_\delta^{(k)}(t)>y^{(k)}(t)$ for $0\leqq t<x$ for each k, but for some k, $y_\delta^{(k)}(x)=y^{(k)}(x)$. Then it follows from (5) that $f(t, y_\delta, \cdots, y_\delta^{(n-1)})-f(t, y, \cdots, y^{(n-1)})<0$ for some t, $0<t<x$, a contradiction, since f is nondecreasing in the last n variables. Hence $y_\delta(x)>y(x)$ for $0\leqq x<b-\eta$.

Let $v(x)$ be the maximal solution of (2) [3, p. 28, Exercise 4.3]. Then by the same argument, if $0<\delta'<\delta$, $y(x)\leqq v(x)<y_{\delta'}(x)<y_\delta(x)$ for $0<x<b-\eta$. But $y_\delta(x)\to y(x)$ and $\eta\to 0$ as $\delta\to 0$, so $y(x)=v(x)$ and (2) has a unique solution to the right of x_0.

REMARKS.

1. If $f(x, y)$ in (1) is also nondecreasing for $x\leqq x_0$, then the above theorem, together with [3, p. 34, remark below Theorem 6.2] gives a two-sided uniqueness theorem.

2. In the special case when $n=1$ and $f(x, y)$ is a function of y alone, the condition $f(y)$ is nondecreasing in y can be dropped [2].

3. The proof of the theorem depends on perturbing the given solution and its derivatives in a special way. The hypotheses of the theorem guarantee that if the initial values in (2) are perturbed by a sufficiently small $\delta>0$, then there exists a corresponding solution u_δ. Furthermore, inequality (5) and the subsequent argument remain valid to show that $u_\delta(x)>y(x)$ for $0\leqq x$. However, as $\delta\to 0$, $u_\delta(x)\to v(x)$, the maximal solution of (2), so that uniqueness cannot be guaranteed.

Some Examples. The initial value problem

$$y^{(n)}=(y^{(n-1)})^{2/3}, \qquad y^{(k)}(0)=0, \qquad k=0, 1, \cdots, n-1, \tag{6}$$

has the solution $y(x)=0$ for all x. On the other hand, letting $u=y^{(n-1)}$, then $u'=u^{2/3}$, $u(0)=0$, which has the solution $u(x)=x^3/27$, and so

$$y(x)=\frac{2x^{n+2}}{9(n+2)!}$$

is also a solution of (6) for all x. Condition (3) in this case is $(y^{(n-1)}(0))^{2/3}\neq 0$, but from (6), $y^{(n-1)}(0)=0$.

As another example consider

$$(7)\quad y^{(n)} = (y^{(n-1)})^{2/3}\exp(y^{(n-1)}), \qquad y^{(k)}(0) = 0, \qquad k = 0, 1, \cdots, n-1.$$

Again $y(x)=0$ is a solution. Letting $u=y^{(n-1)}$, $u(x)$ is defined by the equation

$$x = \int_0^u t^{-2/3}e^{-t}\,dt.$$

As $u\to\infty$, $x\to r_0=\int_0^\infty t^{-2/3}e^{-t}dt<\infty$. Then a second solution is given by

$$y(x) = \int_0^x \frac{(x-t)^{n-2}}{(n-2)!}\,u(t)\,dt,$$

defined on $0\leqq x<r_0<\infty$.

The functions on the right in the previous two examples can be multiplied by arbitrary continuous, nonnegative, nondecreasing functions of x to give other examples.

As a final example consider $y''=(y-x)^{2/3}\exp(y-x)$, $y(0)=0$, $y'(0)=1$. Letting $u=y-x$, $u''=u^{2/3}e^u$, $u(0)=0$, $u'(0)=0$, and a nontrivial solution is defined by

$$x = \int_0^{y-x} \frac{ds}{\sqrt{2\int_0^s t^{2/3}e^t\,dt}}.$$

Again as $y\to\infty$, $x\to r_0<\infty$, while another solution $y(x)=x$ is defined for all x. Here $f(x, y, y')$ is decreasing in x for all $x\neq y$, but $f(x, 0, 1)>0$ for all $x\neq 0$.

ON A CHARACTERIZATION OF DISTRIBUTIONS BY EXPECTED VALUES OF EXTREME ORDER STATISTICS

L. K. CHAN, University of Western Ontario

The expected values of the smallest and largest order statistics X_{1n} and X_{nn}, respectively, in a sample of size n from a distribution with distribution function $u=F(x)$ is defined to be

$$EX_{1n} = n\int_{-\infty}^{\infty} x(1-F(x))^{n-1}dF(x) = n\int_0^1 F^{-1}(u)(1-u)^{n-1}du$$

and

$$EX_{nn} = n\int_{-\infty}^{\infty} x(F(x))^{n-1}dF(x) = n\int_0^1 F^{-1}(u)u^{n-1}du,$$

where $F^{-1}(u)=\inf\{x|\ F(x)\geqq u\}$ (cf. [1], p. 523). Since $0\leqq F(x)\leqq 1$, EX_{1n} and EX_{nn} exist for $n\geqq 2$ if $EX=\int_0^1 F^{-1}(u)du$ exists.

Let $F(x)$ and $G(y)$ be the distribution functions of two distributions such that EX and EY exist. In this note we show that a necessary and sufficient condition that these two distributions are identical is that $EX_{1n}=EY_{1n}$ (or $EX_{nn}=EY_{nn}$) for $n\geqq 1$. The necessary condition is trivial. For the sufficient condition, suppose $EX_{nn}=EY_{nn}$, $n\geqq 1$. Since for every real number t and every positive integer k

$$\left|F^{-1}(u)\sum_{r=0}^{k}\frac{(iut)^r}{r!}\right| \leqq \sum_{r=0}^{\infty}\left|F^{-1}(u)\frac{(ut)^r}{r!}\right| \leqq e^{|t|}\left|F^{-1}(u)\right|$$

and $\int_0^1 e^{|t|}\left|F^{-1}(u)\right|du=e^{|t|}E|X|<\infty$, by the Lebesgue dominated convergence theorem we have

$$\sum_{r=0}^{\infty}\frac{(it)^r}{r!}\int_0^1 F^{-1}(u)\cdot u^r du = \int_0^1 F^{-1}(u)e^{iut}du.$$

Similarly

$$\sum_{r=0}^{\infty}\frac{(it)^r}{r!}\int_0^1 G^{-1}(u)\cdot u^r du = \int_0^1 G^{-1}(u)e^{iut}du.$$

Then by assumption for every real number t

$$\int_0^1 F^{-1}(u)e^{iut}du = \int_0^1 G^{-1}(u)e^{iut}du.$$

By the uniqueness of the Fourier transform this implies that $F^{-1}(u)=G^{-1}(u)$ almost everywhere. The fact that both $F(x)$ and $G(y)$ are nondecreasing and continuous from the right implies that both $F^{-1}(u)$ and $G^{-1}(u)$ are nondecreasing and continuous from the left; hence $F^{-1}(u)=G^{-1}(u)$ for every $0\leqq u\leqq 1$. Therefore we conclude that $F(x)$ and $G(y)$ are identical. The case where $EX_{1n}=EY_{1n}$, $n\geqq 1$ can be similarly proved.

CORRECTION FOR "LATTICE POINT COVERINGS BY PLANE FIGURES"

IVAN NIVEN AND H. S. ZUCKERMAN

The last two sentences in the proof of Lemma 3 in the paper (this MONTHLY, 74 (1967) 353–362) are incorrect. Replacing them with the following will make the argument correct.

We may presume that the angles α_j and α_k (at A_j and A_k) satisfy $0<\alpha_j<\pi/2$, $0<\alpha_k<\pi/2$, for if there is an angle $\theta\geqq\pi/2$ among α_i, α_j, α_k then one of the four half lines emanating from the vertex at θ would intersect the opposite side, so we could take A_i at that vertex. We can presume angle $A_iKA_j\geqq\pi/2$ since the other case follows by symmetry.

In the triangle A_jRP_i choose P_i^* on A_jP_i and R^* on A_jR so that $P_i^*R^*$ is parallel to P_iR and $\overline{P_i^*R^*}=1$. Draw $P_i^*Q_i^*$, with Q_i^* on A_iA_k, parallel to A_jA_k, then $Q_i^*S^*$ parallel to $P_i^*R^*$ with S^* on A_kA_j. Then $P_i^*Q_i^*S^*R^*$ is a parallelogram. We will prove that area $P_i^*Q_i^*S^*R^*\geqq 1$. This will imply that the distance between $P_i^*R^*$ and $Q_i^*S^*$ is at least 1 and hence that a line of lattice points crosses $P_i^*Q_i^*$ and R^*S^*. Since $\overline{P_i^*R^*}=1$ this will imply the existence of a lattice point in the parallelogram and hence in the triangle.

To prove that area $P_i^*Q_i^*S^*R^*\geqq 1$ we write x for the length $\overline{P_iP_i^*}$, and observe that $\overline{Q_iQ_i^*}=x\sin\alpha_j/\sin\alpha_k$. Then we see that

$$\overline{P_i^*Q_i^*}=w_i+x\cos\alpha_j+x\frac{\sin\alpha_j}{\sin\alpha_k}\cos\alpha_k=w_i+x\frac{\sin(\alpha_j+\alpha_k)}{\sin\alpha_k}.$$

Also the distance between the parallel lines P_iQ_i and A_jA_k is 1, so the distance between the parallel lines $P_i^*Q_i^*$ and A_jA_k is $1-x\sin\alpha_j$. Letting $A(x)$ denote the area of $P_i^*Q_i^*S^*R^*$ we have

$$A(x)=\left(w_i+x\frac{\sin(\alpha_j+\alpha_k)}{\sin\alpha_k}\right)(1-x\sin\alpha_j). \tag{1}$$

Now what are the possible values of x? If angle $A_iKA_j=\pi/2$ then P_i^* coincides with P_i and $x=0$. As angle A_iKA_j increases K moves along A_kA_j towards A_j and x increases. Now x increases continuously as K approaches its limiting position, A_j. At the same time R^* approaches A_j and P_i^* moves along A_iA_j, in the direction of A_j, towards some limiting position P_i' where $\overline{P_i'A_j}=1$. Thus x increases to the limiting value $\overline{P_iA_j}-\overline{P_i'A_j}=\operatorname{cosec}\alpha_j-1$. Let Q_i' and S' be the corresponding limiting positions of Q_i^* and S^*. Then $\overline{Q_i'S'}=1$ and $Q_i'S'$ is parallel to A_iA_j. By the hypothesis of the lemma we have $w_k\geqq 1$ and the line of length w_k is at a distance 1 from A_iA_j. Since $\overline{Q_i'S'}=1\leqq w_k$ we see that the distance of $Q_i'S'$ from A_iA_j is at least 1. From this we see that the area of $P_i'A_jS'Q_i'$ is at least 1, that is $A(\operatorname{cosec}\alpha_j-1)\geqq 1$. We also have $A(0)=w_i\geqq 1$ from (1).

Now we know that $A(x)\geqq 1$ at the two endpoints $x=0$ and $x=\operatorname{cosec}\alpha_j-1$. But from (1) we see that $A(x)$ is a quadratic polynomial in x, with negative coefficient of x^2. Hence $A(x)\geqq 1$ for all x satisfying $0\leqq x\leqq\operatorname{cosec}\alpha_j-1$.

MATHEMATICAL NOTES

THE PROBLEM OF REFLECTING QUEENS

D. A. KLARNER, McMaster University

The following problem was posed in [2] as a research problem: Is it possible for $n \geqq 3$ to group the set $\{1, 2, \cdots, 2n\}$ into n pairs (a_i, b_i) with $b_i > a_i$ so that all of the numbers $b_i - a_i$, $b_i + a_i$, $i = 1, 2, \cdots, n$ are distinct? In this note we convert a special form of this problem into a combinatorial game which is directly related to the problem of placing n queens on an $n \times n$ chessboard so that no two queens attack one another.

We will study a more restricted version of the problem posed: For which n is it possible to form pairs $(1, a_1)$, $(2, a_2)$, $\cdots$, (n, a_n) with $\{a_1, a_2, \cdots, a_n\} = \{n+1, n+2, \cdots, 2n\}$, so that all of the numbers $a_i - i$, $a_i + i$, $i = 1, 2, \cdots, n$ are distinct? To see this modified problem in terms of the problem of the queens, we start with an $n \times n$ chessboard with a $1 \times n$ strip of squares added along one side which we call a *reflecting strip*; next, we define a *reflecting queen* to be a standard chess queen with the added power of being able to reflect her path via the reflecting strip. In Fig. 1, we show how two queens normally at peace attack one another when this convention is made.

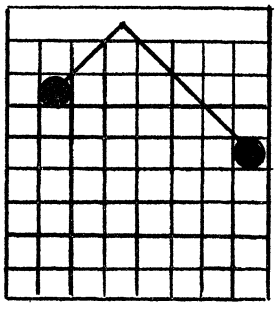

FIG. 1

The problem posed in the preceding paragraph has a solution for a given n if, and only if, it is possible to place n reflecting queens on an $n \times n$ checker board with a reflecting strip so that no pair of queens attack each other. To prove this, number the rows of the $n \times n$ square $1, 2, \cdots, n$ beginning with the first row below the reflecting strip, and number the columns from left to right $n+1, n+2, \cdots, 2n$; the intersection of the ith row and jth column is the (i, j) square. It is easy to see that a reflecting queen on the (i, j) square attacks the following squares provided the coordinates designate squares on the board:

Column squares:	$(i \pm 1, j), (i \pm 2, j), \cdots$
Row squares:	$(i, j \pm 1), (i, j \pm 2), \cdots$

Diagonal squares: $(i \pm 1, j \pm 1), (i \pm 2, j \pm 2), \cdots$

$(i \pm 1, j \mp 1), (i \pm 2, j \mp 2), \cdots$

Reflected diagonal squares: $(1, j \pm (i+1)), (2, j \pm (i+2)), \cdots$

Now it is easy to verify the following statement and its converse: if $(a_1, a_2, \cdots, a_n)$ is a permutation of the numbers $1, 2, \cdots, n$ such that all of the numbers $n+i \pm a_i$, $i=1, 2, \cdots, n$ are distinct, then no pair of reflecting queens placed on the squares $(a_1, n+1), (a_2, n+2), \cdots, (a_n, 2n)$ attack one another. If $(a_1, n+1), (a_2, n+2), \cdots, (a_n, 2n)$ corresponds to a reflecting queens solution, then so does $(a_n, n+1), (a_{n-1}, n+2), \cdots, (a_1, 2n)$, since the latter corresponds to a reflection about the center column of the first solution. Rotations and reflections of solutions of the queens problem are regarded as the same; in the reflecting queens problem the situation is altered. Here the board has only one symmetry (i.e., the one just mentioned) since a rotation shifts the reflecting strip to another edge. Fig. 2 depicts a solution of the queens problem which corresponds to two essentially different solutions of the reflecting queens problem; namely, those corresponding to the sets of pairs (2, 9), (7, 10), (5, 11), (8, 12), (1, 13), (4, 14), (6, 15), (3, 16) and (4, 9), (2, 10), (7, 11), (3, 12), (6, 13), (8, 14), (1, 15), (5, 16).

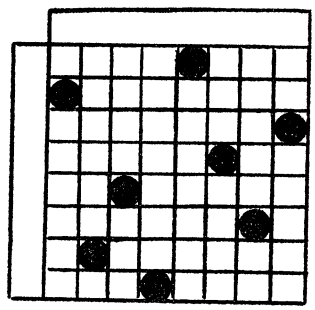

FIG. 2

Kraitchik listed in [1] all of the essentially different solutions of the queens problem for $n=4$, 5, 6 and 8 and gave the number of these solutions, $Q(n)$, for $n \leqq 12$. We list the solutions of the queens problem for $n \leqq 8$ below using the notation for the reflecting queens solutions with $(a_1, a_2, \cdots, a_n)$ an abbreviation of $\{(a_1, n+1), (a_2, n+2), \cdots\}$.

SOLUTIONS OF THE QUEENS PROBLEM

$n=4$: $A=(3, 1, 4, 2)$

$n=5$: $B_1=(3, 1, 4, 2, 5)$, $B_2=(2, 5, 3, 1, 4)$

$n=6$: $C=(4, 1, 5, 2, 6, 3)$

$n=7$: $D_1=(5, 1, 4, 7, 3, 6, 2)$, $D_2=(1, 4, 7, 3, 6, 2, 5)$

$D_3=(4, 7, 3, 6, 2, 5, 1)$, $D_4=(2, 5, 1, 4, 7, 3, 6)$

$D_5=(2, 5, 7, 4, 1, 3, 6)$, $D_6=(3, 1, 6, 2, 5, 7, 4)$

$n=8$: $E_1=(2, 5, 7, 4, 1, 8, 6, 3)$, $E_2=(5, 1, 4, 6, 8, 2, 7, 3)$
$E_3=(5, 7, 1, 4, 2, 8, 6, 3)$, $E_4=(2, 7, 5, 8, 1, 4, 6, 3)$
$E_5=(1, 5, 8, 6, 3, 7, 2, 4)$, $E_6=(1, 6, 8, 3, 7, 4, 2, 5)$
$E_7=(2, 4, 6, 8, 3, 1, 7, 5)$, $E_8=(2, 5, 7, 1, 3, 8, 6, 4)$
$E_9=(2, 6, 1, 7, 4, 8, 3, 5)$, $E_{10}=(2, 7, 3, 6, 8, 5, 1, 4)$
$E_{11}=(3, 6, 2, 5, 8, 1, 7, 4)$, $E_{12}=(3, 5, 2, 8, 1, 7, 4, 6)$

Using this list it is not difficult to check each of the solutions of the queens problem for $n \leqq 8$ and their rotations to find that the reflecting queens problem for $n \leqq 8$ has only the following solutions: $n=4$, A; $n=5$, B_1; $n=6$, none; $n=7$, D_1; $n=8$, E_1, E_2, E_3, E_4, and a rotation of E_4 shown in Figure 2. The number of solutions of the queens problem is 46, 92, 351, and 1787 for $n=9$, 10, 11 and 12 respectively. It seems likely that some of these solutions correspond to reflecting queens solutions, but nothing is known for $n>8$. We are led to conjecture on the basis of this evidence that the reflecting queens problem has at least one solution for every $n>6$; if this were the case, the Shen question would consequently be answered in the affirmative.

CALCULATING THE GENERAL SOLUTION OF A LINEAR DIOPHANTINE EQUATION

JAMES BOND, Indiana University

Weinstock [1] observed the usual proof for the existence of the g.c.d. (greatest common divisor) d of nonzero integers $a_1, \cdots, a_n$ by showing that d is the minimal positive element of the set of all integral combinations of $a_1, \cdots, a_n$ had a computational aspect. He developed an algorithm for determining d which also permitted the determination of integers $x_1, \cdots, x_n$ such that $a_1x_1 + a_2x_2 + \cdots + a_nx_n = d$. The paper ends with the remark that the algorithm gives only particular solutions of the above equation. We show how to obtain a general solution of such an equation by using the algorithm $n-1$ times.

We begin with a short presentation of Weinstock's algorithm based on the division algorithm for least positive remainders. See [1] for the often more effective algorithm based on least absolute value remainders. Suppose $a_1, \cdots, a_n$ are given nonzero integers with g.c.d. d. Choose integers $l_1^{(0)}, \cdots, l_n^{(0)}$ such that $0 < r_0 = a_1l_1^{(0)} + \cdots + a_nl_n^{(0)}$. If $r_0 \mid a_1, r_0 \mid a_2, \cdots, r_0 \mid a_n$ then $r_0 = d$ and we have finished. If not, suppose that $r_0 \nmid a_i$ for some i, $1 \leqq i \leqq n$. Then $a_i = r_0q_1 + r_1$, $0 < r_1 < r_0$, with q_1, r_1 integers. We have $r_1 = a_i - r_0q_1 = a_1l_1^{(1)} + \cdots + a_nl_n^{(1)}$, where $l_1^{(1)} = -q_1l_1^{(0)}, \cdots, l_{i-1}^{(1)} = -q_1l_{i-1}^{(0)}$, $l_i^{(1)} = 1 - q_1l_i^{(0)}l_{i+1}^{(0)} = -q_1l_{i+1}^{(0)}, \cdots, l_n^{(1)} = -q_1l_n^{(0)}$. After a finite number of steps we may suppose an index k reached for the first time for which $r_k \mid a_1, \cdots, r_k \mid a_n$, hence $d = r_k = a_1l_1^{(k)} + \cdots + a_nl_n^{(k)}$.

We now exhibit the general solution of a linear Diophantine equation in a form suitable for the purpose of this note. Given nonzero integers $a_1, \cdots, a_n$,

let $d_1=a_1$, $d_2=$g.c.d. of a_1 and a_2, $\cdots$, $d_n=$g.c.d. of $a_1, \cdots, a_n$. Then the general solution in integers of the equation

$a_1x_1+a_2x_2+\cdots+a_nx_n=t_nd_n$, t_n an integer, $n\geqq 2$, is given by

$$\begin{aligned}
x_1 &= t_nx_1^{(n)} + t_{n-1}\frac{a_n}{d_n}\,x_1^{(n-1)} + t_{n-2}\frac{a_{n-1}}{d_{n-1}}\,x_1^{(n-2)} + \cdots + t_1\frac{a_2}{d_2}\\
x_2 &= t_nx_2^{(n)} + t_{n-1}\frac{a_n}{d_n}\,x_2^{(n-1)} + t_{n-2}\frac{a_{n-1}}{d_{n-1}}\,x_2^{(n-2)} + \cdots - t_1\frac{d_1}{d_2}\\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\
x_{n-1} &= t_nx_{n-1}^{(n)} + t_{n-1}\frac{a_n}{d_n}\,x_{n-1}^{(n-1)} - t_{n-2}\frac{d_{n-2}}{d_{n-1}}\\
x_n &= t_nx_n^{(n)} - t_{n-1}\frac{d_{n-1}}{d_n}
\end{aligned}$$

where $t_1, \cdots, t_{n-1}$ are arbitrary integers, $d_2=a_1x_1^{(2)}+a_2x_2^{(2)}$, $d_3=a_1x_1^{(3)}+a_2x_2^{(3)}+a_3x_3^{(3)}$, $\cdots$, and $d_n=a_1x_1^{(n)}+\cdots+a_nx_n^{(n)}$.

We give only the inductive step necessary for proving this result. Suppose the result proved for $n=k$, $k\geqq 2$. Let $x_1^{(k+1)}, \cdots, x_{k+1}^{(k+1)}$ be a solution of $a_1x_1+\cdots+a_{k+1}x_{k+1}=d_{k+1}$ and suppose that $x_1, \cdots, x_{k+1}$ is a solution of $a_1x_1+\cdots+a_{k+1}x_{k+1}=t_{k+1}d_{k+1}$, with $a_1, \cdots, a_{k+1}, t_{k+1}$ nonzero integers. Then

$$a_1(x_1 - t_{k+1}x_1^{(k+1)}) + \cdots + a_{k+1}(x_{k+1} - t_{k+1}x_{k+1}^{(k+1)}) = 0$$

which we rewrite as

$$\frac{a_1}{d_{k+1}}(x_1 - t_{k+1}x_1^{(k+1)}) + \cdots + \frac{a_k}{d_{k+1}}(x_k - t_{k+1}x_k^{(k+1)}) = -\frac{a_{k+1}}{d_{k+1}}(x_{k+1} - t_{k+1}x_{k+1}^{(k+1)}).$$

Since $a_1/d_{k+1}, \cdots, a_{k+1}/d_{k+1}$ are relatively prime, this equation holds if and only if

$$x_{k+1} - t_{k+1}x_{k+1}^{(k+1)} = (-t_k)\frac{d_k}{d_{k+1}}.$$

For each choice of an integer t_k, by induction

$$\begin{aligned}
x_1 - t_{k+1}x_1^{(k+1)} &= t_k\frac{a_{k+1}}{d_{k+1}}\,x_1^{(k)} + t_{k-1}\frac{a_k/d_{k+1}}{d_k/d_{k+1}}\,x_1^{(k-1)} + \cdots + t_1\frac{a_2/d_{k+1}}{d_2/d_{k+1}}\\
x_2 - t_{k+1}x_2^{(k+1)} &= t_k\frac{a_{k+1}}{d_{k+1}}\,x_2^{(k)} + t_{k-1}\frac{a_k/d_{k+1}}{d_k/d_{k+1}}\,x_2^{(k-1)} + \cdots - t_1\frac{d_1/d_{k+1}}{d_2/d_{k+1}}\\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\\
x_k - t_{k+1}x_k^{(k+1)} &= t_k\frac{a_{k+1}}{d_{k+1}}\,x_k^{(k)} - t_{k-1}\frac{d_{k-1}/d_{k+1}}{d_k/d_{k+1}},
\end{aligned}$$

where $t_1, \cdots, t_{k-1}$ are arbitrary integers and

$$\frac{a_1}{d_{k+1}} x_1^{(i)} + \cdots + \frac{a_i}{d_{k+1}} x_i^{(i)} = \frac{d_i}{d_{k+1}}, \qquad \text{for } i = 2, \cdots, k.$$

Transposing the terms involving t_{k+1} to the right side and simplifying, we obtain the desired form for $x_1, \cdots, x_{k+1}$. It is easy to verify that each choice of integers $t_1, \cdots, t_k$ does lead to a solution in integers of $a_1x_1 + \cdots + a_{k+1}x_k = t_{k+1}d_{k+1}$.

Once the general solution of a linear Diophantine equation is seen to be in the above form it remains only to determine $d_2, \cdots, d_n$, and $x_1^{(2)}, x_2^{(2)}, \cdots, x_1^{(n)}, \cdots, x_n^{(n)}$. Apply Weinstock's algorithm to $\{a_1, a_2\}$ to obtain $r_{k_2}, l_1^{(k_2)}, l_2^{(k_2)}$ such that $d_2 = r_{k_2} = a_1l_1^{(k_2)} + a_2l_2^{(k_2)}$. Next apply Weinstock's algorithm to $\{a_1, a_2, a_3\}$ to obtain $r_{k_3}, l_1^{(k_3)}, l_2^{(k_3)}, l_3^{(k_3)}$ such that $d_3 = r_{k_3} = a_1l_1^{(k_3)} + a_2l_2^{(k_3)} + a_3l_3^{(k_3)}$. We may continue in this manner finally obtaining $r_{k_n}, l_1^{(k_n)}, \cdots, l_n^{(k_n)}$ such that $d_n = r_{k_n} = a_1l_1^{(k_n)} + \cdots + a_nl_n^{(k_n)}$. Set $x_1^{(2)} = l_1^{(k_2)}, x_2^{(2)} = l_2^{(k_2)}, \cdots, x_1^{(n)} = l_1^{(k_n)}, \cdots, x_n^{(n)} = l_n^{(k_n)}$.

SUBDIRECTLY IRREDUCIBLE UNARY ALGEBRAS

MICHAEL YOELI, Technion, Haifa, Israel

I. Introduction. In this paper we are concerned with systems $\boldsymbol{A} = (A, \Gamma)$, where A is a finite set (of *points*) and Γ is a transformation of A, i.e., a function $\Gamma: A \to A$. Such a system is called a (finite) *unary algebra* [1], i.e., an abstract algebra with a single unary operation. Alternatively, it can be considered as complete transition graph [2], i.e., a directed graph with exactly one edge issuing from each vertex. Representations of arbitrary abstract algebras as subsystems of direct products have been studied extensively by means of lattices of congruences [3]. In this paper we consider such *subdirect* representations of unary algebras, applying simple structural properties of their graphs. Our main result gives necessary and sufficient conditions for unary algebras represented by a connected graph to be irreducible, i.e., to have only trivial subdirect representations.

The results obtained are applicable to the technically significant problem of synthesizing single-input sequential machines (automata) by parallel composition [4]. For more information on sequential machine compositions (automata products) the reader is referred to [5] and the further bibliography given there.

II. Statement of main theorem. Henceforth let $\boldsymbol{A} = (A, \Gamma)$, $\boldsymbol{A}_1 = (A_1, \Gamma_1)$, etc., denote unary algebras. The image of $a \in A$ under Γ will be denoted by $a\Gamma$.

DIRECT PRODUCT. $\boldsymbol{A} = \boldsymbol{A}_1 \times \boldsymbol{A}_2$ means that $A = A_1 \times A_2$ and that Γ is defined componentwise: $(a_1, a_2)\Gamma = (a_1\Gamma_1, a_2\Gamma_2)$.

SUBALGEBRA. $A_1 \subseteq A_2$ means that $A_1 \subseteq A_2$, and that Γ_1 is the restriction of Γ_2 to A_1. Thus, A_1 has to be closed under Γ_2. $\boldsymbol{A}_1 \leqq \boldsymbol{A}_2$ will mean that $\boldsymbol{A}_1$ is isomorphic to some subalgebra of $\boldsymbol{A}_2$.

$\boldsymbol{A}$ is *irreducible* if $\boldsymbol{A} \leqq \boldsymbol{A}_1 \times \boldsymbol{A}_2$ always implies that either $\boldsymbol{A} \leqq \boldsymbol{A}_1$ or $\boldsymbol{A} \leqq \boldsymbol{A}_2$. $\boldsymbol{A}$ is a *cycle* of length n, if its points can be ordered to form a sequence $(x_0, x_1, \cdots, x_{n-1})$ such that $x_{i-1}\Gamma = x_i (i = 1, \cdots, n-1)$ and $x_{n-1}\Gamma = x_0$.

$\boldsymbol{A}$ is *connected*, if it contains only one cycle as subgraph. One easily verifies that $\boldsymbol{A}$ is connected iff the corresponding graph (considered as a nonoriented graph) is connected.

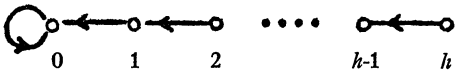

FIG. 1. Graph of unary algebra J_h

For any positive integer h we denote by J_h the unary algebra indicated in Fig. 1. We have:

THEOREM 1. *A connected unary algebra A is irreducible, iff $\boldsymbol{A}$ is either a cycle of length n, where n is a power of a prime number, or $\boldsymbol{A} \cong J_h$ for some $h \geqq 1$.*

III. Proof of main theorem. To prove Theorem 1, we shall derive some lemmas, and introduce some additional notation and terminology (cf. [1]).

For any positive integers n_1 and n_2 we denote by (n_1, n_2) and $[n_1, n_2]$ their g.c.d. and l.c.m., respectively. The following result is well known and easily verified.

LEMMA 1. *If $\boldsymbol{A}_1$ and $\boldsymbol{A}_2$ are connected unary algebras containing cycles of lengths n_1 and n_2 respectively, then $\boldsymbol{A}_1 \times \boldsymbol{A}_2$ contains (n_1, n_2) cycles, each of length $[n_1, n_2]$.*

If $A_1 \cap A_2 = \varnothing$, we set $\boldsymbol{A} = \boldsymbol{A}_1 + \boldsymbol{A}_2$, where $A = A_1 \cup A_2$ and $a_i\Gamma = a_i\Gamma_i$ for every $a_i \in A_i (i = 1, 2)$.

Clearly, every unary algebra is the sum of connected unary algebras, and the operation $\times$ is distributive with respect to $+$. Hence

LEMMA 2. *If $\boldsymbol{A}$ is a connected unary algebra, and $\boldsymbol{A} \leqq \boldsymbol{A}_1 \times \boldsymbol{A}_2$, then there exist connected unary algebras $\boldsymbol{A}_1'$ and $\boldsymbol{A}_2'$ such that $\boldsymbol{A}_i' \subseteq \boldsymbol{A}_i$ $(i = 1, 2)$ and $\boldsymbol{A} \leqq \boldsymbol{A}_1' \times \boldsymbol{A}_2'$.*

A further, rather evident result is the following:

LEMMA 3. *A cycle of length n is irreducible, iff n is some power of a prime number.*

If Γ is a transformation of the set A, we define Γ^r, $r \geqq 0$, as usual: $a\Gamma^0 = a$, $a\Gamma^{r+1} = (a\Gamma^r)\Gamma$, for every $a \in A$.

If a and b are points of $\boldsymbol{A}$, such that $a\Gamma^r = b$, for some $r \geqq 0$, then a is a *predecessor* of b. $P(a)$ will denote the set of all predecessors of a. The height $|a|$ of a point a is the least integer $r \geqq 0$, for which $a\Gamma^r$ is *cyclic* (i.e., belongs to a cycle). We set $|\boldsymbol{A}| = \max_{a \in A} |a|$. Let $\boldsymbol{A} = \boldsymbol{A}_1 \times \boldsymbol{A}_2$.

If $a=(a_1, a_2)$ is a point of $\boldsymbol{A}$, then $a\Gamma^r=(a_1\Gamma_1^r, a_2\Gamma_2^r)$ is cyclic, iff both $a_1\Gamma_1^r$ and $a_2\Gamma_2^r$ are cyclic. Hence

LEMMA 4. $|\boldsymbol{A}_1\times\boldsymbol{A}_2| = \max(|\boldsymbol{A}_1|, |\boldsymbol{A}_2|)$.

A simple consequence is the following:

LEMMA 5. *For every $h\geqq 1$, the unary algebra J_h (Fig. 1) is irreducible.*

A unary algebra is *basic* [1], if it is connected and its cycle has length 1. We shall now prove

LEMMA 6. *If $\boldsymbol{A}$ is a basic unary algebra which contains at least two points of height 1, then $\boldsymbol{A}$ is reducible.*

Proof. Let x be the unique cyclic point of $\boldsymbol{A}$, and $a\neq b$ two points of height 1. Let $\boldsymbol{A}_1$ and $\boldsymbol{A}_2$ be the subalgebras of $\boldsymbol{A}$, such that $A_1=\{x\}\cup P(a)$ and $A_2=A-P(a)$. Since $b\notin A_1$ and $a\notin A_2$, the $\boldsymbol{A}_i$ are *proper* subalgebras of $\boldsymbol{A}$. One easily verifies that $\boldsymbol{A}\leqq\boldsymbol{A}_1\times\boldsymbol{A}_2$. Thus, $\boldsymbol{A}$ is reducible.

Let $\boldsymbol{A}=(A, \Gamma)$ and $A_1\subseteq A$. We define $\boldsymbol{A}/A_1$ to be the unary algebra (A_1, Γ_1), where $a_1\Gamma_1=a_1\Gamma$ if both a_1 and $a_1\Gamma$ belong to A_1, whereas $a_1\Gamma_1=a_1$ if $a_1\in A_1$, but $a_1\Gamma\notin A_1$.

Next, we prove the following

LEMMA 7. *Let $\boldsymbol{A}$ be a basic unary algebra and let $|\boldsymbol{A}|=h\geqq 1$. Then $\boldsymbol{A}$ is irreducible, iff $\boldsymbol{A}\cong J_h$.*

Proof. If $\boldsymbol{A}\cong J_h$, then A is irreducible, by Lemma 5. Assume now that $\boldsymbol{A}$ is irreducible. By Lemma 6, and since $|\boldsymbol{A}|\geqq 1$, there exists exactly one point a_1 of height 1.

We set $\boldsymbol{A}_1=\boldsymbol{A}/P(a_1)$. Then $\boldsymbol{A}\leqq\boldsymbol{A}_1\times J_h$. Indeed, one easily verifies that $\boldsymbol{A}$ is isomorphic to $(\boldsymbol{A}_1\times J_h)/A_2$, where

$$A_2=\{(a, |a|)\mid a\in P(a_1)\}\cup\{(a_1, 0)\}.$$

$\boldsymbol{A}$ was assumed to be irreducible. Since $P(a_1)$, the set of points of $\boldsymbol{A}_1$, is a proper subset of A, we must have $\boldsymbol{A}\leqq J_h$, where $|\boldsymbol{A}|=h$. Hence $\boldsymbol{A}\cong J_h$.

Let $\boldsymbol{A}=(A, \Gamma)$ be an arbitrary unary algebra and x a cyclic point of $\boldsymbol{A}$. We set $T(x)=\{a\mid a\in A \text{ and } a\Gamma^{|a|}=x\}$. Then $\boldsymbol{A}/T(x)$ is basic and we have

LEMMA 8. *Let $\boldsymbol{A}_1$ be a basic unary algebra with cyclic point x_1, $\boldsymbol{A}_2$ a cycle, and x_2 a point of $\boldsymbol{A}_2$. Then $(\boldsymbol{A}_1\times\boldsymbol{A}_2)/T(x_1, x_2)\cong\boldsymbol{A}_1$.*

Proof. Consider the mapping $\eta: a_1\to(a_1, a_2)$ of A_1 into $A_1\times A_2$, where a_2 is the point of $\boldsymbol{A}_2$ determined by $a_2\Gamma^{|a_1|}=x_2$. It is easily seen that this mapping η is an isomorphism of $\boldsymbol{A}_1$ onto $(\boldsymbol{A}_1\times\boldsymbol{A}_2)/T(x_1, x_2)$.

LEMMA 9. *Let $\boldsymbol{A}$ be a connected unary algebra with a cycle of length $n>1$, such that $|\boldsymbol{A}|\geqq 1$. Then $\boldsymbol{A}$ is reducible.*

Proof. Let $\boldsymbol{A}_1$ be the basic algebra obtained from $\boldsymbol{A}$ by identifying all its

cyclic points, and A_2 the cycle of A. Then $A_1 \times A_2$ is a connected unary algebra with cycle length n. Let x_1 be the cyclic point of A_1 and x, x_2 arbitrary cycle points of A and A_2, respectively. Clearly $A/T(x) \leqq A_1$. Hence, by Lemma 8, $A/T(x) \leqq (A_1 \times A_2)/T(x_1, x_2)$. This implies that $A \leqq A_1 \times A_2$. Since both A_1 and A_2 have fewer points than A, A is reducible. We are now in a position to prove Theorem 1.

Proof of Theorem 1. The "if" part follows immediately from Lemmas 3 and 5. Let now A be a connected unary algebra which is irreducible. Let n be the cycle length of A. If $n=1$, i.e., A is basic, and $|A| = h \geqq 1$, then by Lemma 7, $A \cong J_h$. If $n=1$ and $|A| = 0$, then A is a cycle of length 1. If $n>1$, then by Lemma 9, $|A| = 0$, i.e., A is a cycle of length n. By Lemma 3, n is a power of a prime number. This completes the proof.

ON A THEOREM OF JENSEN

R. S. KULKARNI, Harvard University

Let K be a finite algebraic number field, L a finite extension of K, A (resp. B) ring of integers in K (resp. L). Fröhlich [1] has completely determined the structure of B as an A-module. Jensen [2] has obtained corresponding results when L is an infinite algebraic extension of K, in particular, he proved that in this case, there always exist relative integral bases; he also obtained necessary and sufficient conditions for B-submodules of L to have a free A-basis.

In this note, we give a characterization of countably generated projective modules over a Dedekind domain. Use of condition (2) in the theorem immediately yields Jensen's results. Jensen's proofs seem to be somewhat complicated.

Jensen pointed out to me that this formulation may be regarded as a generalization of Pontryagin's theorem; cf. L. Fuchs [3, Section 14].

THEOREM. *Let A be a Dedekind domain, and K its quotient field. Let P be a torsion-free A-module of countable rank, i.e.,* $\dim_K P \otimes_A K \leqq \aleph_0$.

Then the following conditions are equivalent:

(1) *P is projective.*

NO GRAPH IS PERFECT

MEHDI BEHZAD, Wayne State University and Pahlavi University, Iran, and
GARY CHARTRAND, University of Michigan and Western Michigan University

Given a finite sequence of nonnegative integers $s_1 \leqq s_2 \leqq \cdots \leqq s_p$, it is not an easy matter, in general, to determine whether these numbers are the degrees of the points of some graph with p points. Certainly, if such a graph G exists, then $0 \leqq s_i \leqq p-1$ for each i and Σs_i is even (for this is twice the number of lines of G), but these conditions fall far short of being sufficient. Methods have been devised to test whether a given sequence of integers is "graphical" (see [1], [2]), but the procedures involved are often tedious.

It is the object of this note to show that with certain sequences, the question of whether they are graphical can be answered quickly.

The only graphs under consideration here are ordinary graphs, i.e., finite, undirected graphs without loops or multiple lines. We denote the degree of a point v in G (the number of lines of G incident with v) by $\deg v$.

A graph with two or more points is called *perfect* if for each pair of distinct points u and v, $\deg u \neq \deg v$, i.e., no two points have the same degree.

THEOREM 1. *No graph is perfect.*

Proof. If G is perfect and has p points $v_1, v_2, \cdots, v_p$, where $\deg v_i < \deg v_{i+1}$, then since $0 \leqq \deg v_i \leqq p-1$, it follows that $\deg v_i = i-1$ for $i = 1, 2, \cdots, p$. This implies, however, that v_1 is adjacent to no points of G while v_p is adjacent to all other points of G, which is clearly impossible. Hence, no graph is perfect.

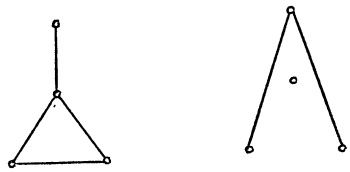

FIG. 1

Since no sequence of distinct integers can be graphical, we consider those sequences in which exactly two integers are equal. A graph with at least two points is *quasiperfect* if there are precisely two points with the same degree. Contrary to the situation with perfect graphs, quasiperfect graphs do exist. Each of the graphs of Figure 1 has 4 points and is quasiperfect.

The *complement* $\overline{G}$ of a graph G is the graph having the same points as G and in which two points are adjacent if and only if these two points are not adjacent in G.

The following two observations concern quasiperfect graphs with p points,

the first of which is a direct result of the fact that if a point v of G has degree s, then v has degree $p-s-1$ in $\overline{G}$.

Remark 1. $\overline{G}$ is quasiperfect if and only if G is.

Remark 2. A quasiperfect graph with $p \geqq 3$ points has either exactly one point of degree $p-1$ or exactly one of degree 0.

Concerning Remark 2, since all degrees lie among the p integers $0, 1, \cdots, p-1$, the degrees of the points of a quasiperfect graph G take on all these values except one. Hence, at least one of 0 and $p-1$ is the degree of a point of G. We have already seen that no graph can contain both a point of degree 0 and one of degree $p-1$. If a quasiperfect graph with at least 3 points contains two points of degree 0 (or, equivalently, two of degree $p-1$) then the deletion of one of these results in a perfect graph, contrary to Theorem 1.

THEOREM 2. *For every integer $p \geqq 2$, there are exactly two nonisomorphic quasiperfect graphs with p points. Furthermore, these two graphs are complementary and the equal degrees are $[p/2]$ in the connected graph and $[(p-1)/2]$ in the disconnected graph.*

Proof. We proceed by induction on p, with the theorem being obvious for $p=2$. Assume that the result holds for $p=n$, $n \geqq 2$, the connected graph being G_1 and its disconnected complement G_2. Two quasiperfect graphs H_1 and H_2 with $n+1$ points can be constructed by adding a new point to G_1 and adding a new point adjacent to all points of G_2, respectively. Clearly, H_1 and H_2 are nonisomorphic complementary graphs. That these are the only quasiperfect graphs with $n+1$ points is readily observed, for if G is any quasiperfect graph with $n+1$ points, the removal of the point having degree 0 or n results in either G_1 or G_2, implying that G is H_1 or H_2, respectively.

By hypothesis, the equal degrees in G_1 are $[n/2]$. These points with the equal degrees have the same degrees in the disconnected graph H_1, and the result follows by observing that $[n/2]=[((n+1)-1)/2]$. The equal degrees in G_2 are $[(n-1)/2]$, and so the equal degrees in H_2 are $[(n-1)/2]+1=[(n+1)/2]$.

Theorem 2 thus implies that a sequence of p integers having exactly two equal terms is graphical if and only if the sequence is either 0 through $p-2$ with $[(p-1)/2]$ appearing twice or 1 through $p-1$ with $[p/2]$ appearing twice, and in each case, the corresponding graph is unique up to isomorphism.

AN ELEMENTARY AND SIMPLE PROOF OF THE CONNECTEDNESS OF THE CLASSICAL GROUPS

YUNG-CHOW WONG AND YIK-HOI AU-YEUNG, University of Hong Kong

In his book [1], C. Chevalley, whose notations we follow, considers the connected classical groups $GL(n, C)$, $SL(n, C)$, $U(n)$, $SU(n)$, $SO(n)$, $SO(n, C)$, $SL(n, R)$, $Sp(n)$ and $Sp(n, C)$, and proves by topological methods the connectedness of $GL(n, C)$, $U(n)$, $SU(n)$, $SO(n)$ and $Sp(n)(n \geqq 1)$ ([1], p. 16 and p. 37). On the other hand H. Weyl has proved by algebraic methods that $U(n)$ is arcwise connected ([2], p. 194) and $SU(n)$ is simply connected ([2], p. 268). Furthermore, E. Sperner has proved by algebraic methods that the set of all real matrices with positive (resp. negative) determinant is arcwise connected ([3], p. 160).

In this note, we give an elementary and simple proof of the arcwise connectedness of all the classical groups. (Since the classical groups are all manifolds, their connectedness is equivalent to their arcwise connectedness.) The idea of the proof is: Let Γ be the group under consideration. We shall find in Γ a fixed element E such that for any $A \in \Gamma$, there is an arc $A(t)$, $0 \leqq t \leqq 1$, in Γ with $A(0) = E$ and $A(1) = A$. In fact, in the case of the group $Sp(n, C)$, we shall take

$$E = \begin{pmatrix} O & I \\ -I & O \end{pmatrix},$$

where O, I are respectively the $n \times n$ zero matrix and the $n \times n$ identity matrix. In all the other cases we shall take $E = I$. The construction of the arc $A(t)$ is based entirely on known theorems in matrix theory.

THEOREM. *Each of the classical groups $GL(n, C)$, $SL(n, C)$, $U(n)$, $SU(n)$, $SO(n)$, $SO(n, C)$, $SL(n, R)$, $Sp(n)$ and $Sp(n, C)$ is arcwise connected.*

Proof. In the proof all the matrices considered are of order $n(\geqq 1)$ unless stated otherwise. We shall denote by $(K_1, \cdots, K_p)$ a diagonal block matrix with the square matrix $K_1, \cdots, K_p$ lying on its diagonal.

(a) *The connectedness of $GL(n, C)$.* Let $A_1 \in GL(n, C)$. Then there exists a complex matrix P such that

$$A_1 = \exp P$$

([4], p. 18). The arc required is $A_1(t) = \exp(tP)$.

(b) *The connectedness of $SL(n, C)$.* Let $A_2 \in SL(n, C)$. Then there exists a complex matrix P such that

$$A_2 = \exp P$$

and trace $P = 2k\pi\sqrt{-1}$ for some integer k. The arc required is

$$A_2(t) = \exp(tP) \exp(tQ),$$

where $Q = (0, \cdots, 0, -2k\pi\sqrt{-1})$.

(c) *The connectedness of* $U(n)$. Let $A_3 \in U(n)$. Then we can write

$$A_3 = U(\exp(a_1\sqrt{-1}), \cdots, \exp(a_n\sqrt{-1}))U^{-1},$$

where $U \in U(n)$ and $a_1, \cdots, a_n$ are real numbers ([5], p. 274). The arc required is

$$A_3(t) = U(\exp(ta_1\sqrt{-1}), \cdots, \exp(ta_n\sqrt{-1}))U^{-1}.$$

(d) *The connectedness of* $SU(n)$. Let $A_4 \in SU(n)$. Then A_4 can be expressed in the same form as the A_3 in (c) but with the additional condition that $\sum_{i=1}^{n} a_i = 2k\pi$ for some integer k. The arc required is

$$A_4(t) = U(\exp(ta_1\sqrt{-1}), \cdots, \exp(ta_{n-1}\sqrt{-1}), \exp(t(a_n - 2k\pi)\sqrt{-1}))U^{-1}.$$

(e) *The connectedness of* $SO(n)$. Let $A_5 \in SO(n)$. Then we can write

$$A_5 = V(K_1, \cdots, K_q, 1, \cdots, 1)V^{-1},$$

where $V \in O(n)$, q is zero or some positive integer $\leqq n/2$, and

$$K_\lambda = \begin{pmatrix} \cos\theta_\lambda & \sin\theta_\lambda \\ -\sin\theta_\lambda & \cos\theta_\lambda \end{pmatrix} \qquad (\lambda = 1, \cdots, q)$$

([5], p. 285). If we put

$$K_\lambda(t) = \begin{pmatrix} \cos(t\theta_\lambda) & \sin(t\theta_\lambda) \\ -\sin(t\theta_\lambda) & \cos(t\theta_\lambda) \end{pmatrix} \qquad (\lambda = 1, \cdots, q),$$

then the arc required is

$$A_5(t) = V(K_1(t), \cdots, K_q(t), 1, \cdots, 1)V^{-1}.$$

(f) *The connectedness of* $SO(n, C)$. Let $A_6 \in SO(n, C)$. Then we can write

$$A_6 = A_5 \exp(\sqrt{-1}\, D),$$

where $A_5 \in SO(n)$ and D is a real skew-symmetric matrix ([6], p. 4). The arc required is

$$A_6(t) = A_5(t)\exp(t\sqrt{-1}D),$$

where $A_5(t)$ is constructed from A_5 as in (e).

(g) *The connectedness of* $SL(n, R)$. Let $A_7 \in SL(n, R)$. Then we can write

$$A_7 = FA_5,$$

where $A_5 \in SO(n)$ and F is a real positive definite symmetric matrix with determinant 1 ([5], p. 286 and p. 274). Let

$$F = V(\exp a_1, \cdots, \exp a_n)V^{-1},$$

where $V \in O(n)$ and $a_1, \cdots, a_n$ are real numbers such that $\sum_{i=1}^{n} a_i = 0$ ([5], p. 285). Then the arc required is

$$A_7(t) = V(\exp(ta_1), \cdots, \exp(ta_n))V^{-1}A_5(t),$$

where $A_5(t)$ is constructed from A_5 as in (e).

(h) *The connectedness of* $Sp(n)$. Let $A_8 \in Sp(n)$. Then we can write

$$A_8 = W(\exp(a_1\sqrt{-1}), \cdots, \exp(a_n\sqrt{-1}))W^{-1},$$

where $W \in Sp(n)$ and $a_1, \cdots, a_n$ are real numbers [7]. The arc required is

$$A_8(t) = W(\exp(ta_1\sqrt{-1}), \cdots, \exp(ta_n\sqrt{-1}))W^{-1}.$$

(i) *The connectedness of* $Sp(n, C)$. Let $A_9 \in Sp(n, C)$. Then we can write

$$A_9 = \begin{pmatrix} J & I-J \\ -(I-J) & J \end{pmatrix}\begin{pmatrix} I & O \\ G & I \end{pmatrix}\begin{pmatrix} I & H \\ O & I \end{pmatrix}\begin{pmatrix} A & O \\ O & A'^{-1} \end{pmatrix}$$

$$= \begin{pmatrix} I & O \\ 2J & I \end{pmatrix}\begin{pmatrix} J & I-J \\ -(I+J) & J \end{pmatrix}\begin{pmatrix} I & O \\ G & I \end{pmatrix}\begin{pmatrix} I & H \\ O & I \end{pmatrix}\begin{pmatrix} A & O \\ O & A'^{-1} \end{pmatrix}$$

where each of the factors belongs to $Sp(n, C)$, A is nonsingular, A' is the transpose of A, G and H are both symmetric, and J is a diagonal matrix such that $J^2 = J$ [8]. Let P be a complex matrix such that $A = \exp P$, and let P' be the transpose of P. Then the arc required is

$$A_9(t) = \begin{pmatrix} I & O \\ 2tJ & I \end{pmatrix}\begin{pmatrix} tJ & I-tJ \\ -(I+tJ) & tJ \end{pmatrix}\begin{pmatrix} I & O \\ tG & I \end{pmatrix}\begin{pmatrix} I & tH \\ O & I \end{pmatrix}\begin{pmatrix} \exp(tP) & O \\ O & \exp(-tP') \end{pmatrix}.$$

REMARK. By the methods used in (e), (f) and (g), one can also prove respectively that the set of all matrices in $O(n)$ with determinant equal to -1, the set of all matrices in $O(n, C)$ with determinant equal to -1, and the set of all real matrices with positive (resp. negative) determinant are all arcwise connected.

ON ITERATES OF EULER'S ϕ-FUNCTION

J. C. PARNAMI, Panjab University, India

1. Let $\phi_n(m)$ be the iterated ϕ-function such that $\phi_1(m)=\phi(m)$, $\phi_n(m)=\phi(\phi_{n-1}(m))$, and let $w(m)=n$ denote the smallest n for which $\phi_n(m)=1$.

In a problem in this MONTHLY, 71 (1964) p. 1047, Douglas Lind has stated that if

$$m \leqq 2^{\alpha} \quad \text{then} \quad w(m) \leqq \alpha.$$

A proof of this has been given by Satish Kumar Gupta. Here I prove the following two theorems, suggested by Professor Gupta.

THEOREM 1. *If* $m>2\cdot 3^j$, *then* $w(m)>j+1$.

THEOREM 2. $[\log_3 (3m)] \leqq w(m) \leqq [\log_2 (2m)]$.

2. LEMMA 1. *If* $m=2^{\alpha}\cdot m_1$; *where* $m_1 \geqq 2$, *then* $w(m)\geqq \alpha+1$.

Proof. For $\alpha=1$, we have $m\geqq 4$; and $w(m)\geqq 2$. Therefore the lemma is true for $\alpha=1$.

Let the lemma be true for $\alpha\leqq\beta$. To show that the lemma holds for $\alpha=\beta+1$, let $m=2^{\beta+1}\cdot m_1$, where $m_1\geqq 2$.

CASE 1. When m_1 is odd, then $\phi(m)=2^{\beta}\cdot\phi(m_1)$. Since $\phi(m_1)\geqq 2$; by the induction hypothesis, $w(\phi(m))\geqq\beta+1$. Hence $w(m)\geqq\beta+2$.

CASE 2. When m_1 is even, let $m_1=2^{\gamma}\cdot m_2$, where m_2 is odd and $\gamma\geqq 1$; then $m=2^{\beta+\gamma+1}\cdot m_2$. Therefore, $\phi(m)=2^{\beta+\gamma}\cdot\phi(m_2)=2^{\beta}\cdot(2^{\gamma}\cdot\phi(m_2))$. Hence $w(\phi(m))\geqq\beta+1$, so that $w(m)\geqq\beta+2$. This proves the lemma.

LEMMA 2. *If* $m=2^{\alpha}\cdot m_1$, *where* $m_1>3^{\delta}$ *and* $\alpha\geqq 1$, *then* $w(m)>\alpha+\delta$.

Proof. For $\delta=0$, the result is a direct consequence of Lemma 1. For $\delta=1$, let $m_1=2^{\beta}\cdot\gamma$, where γ is odd.

If $\beta\geqq 1$, then we have $m=2^{\alpha+1}\cdot(2^{\beta-1}\cdot\gamma)$, and $2^{\beta-1}\cdot\gamma=m_1/2\geqq 2$. Hence, by Lemma 1,

$$w(m) \geqq \alpha+2>\alpha+1.$$

If $\beta=0$, then $\phi(m)=2^{\alpha-1}\cdot\phi(m_1)$, since m_1 is odd and >3, $\phi(m)$ is even and $\geqq 4$. Therefore $\phi(m)=2^{\alpha}\cdot(\phi(m_1)/2)$.

Now by Lemma 1, $w(\phi(m))\geqq\alpha+1$, i.e., $w(m)\geqq\alpha+2>\alpha+1$, so the lemma is true for $\delta=1$.

Suppose that the lemma holds for $\delta\leqq j-1$. To prove the lemma for $\delta=j$, we proceed as follows:

CASE 1. When m_1 is even, we have $m=2^{\alpha+1}\cdot(m_1/2)$. Here $m_1/2>3^j/2>3^{j-1}$, therefore

$$w(m)>\alpha+1+j-1=\alpha+j.$$

CASE 2. When m_1 is odd, let $m_1 = p_{11}^{\beta} \cdot p_{22}^{\beta} \cdot \cdots \cdot p_{rr}^{\beta}$, $r \geqq 1$, where p_i's are distinct prime $\geqq 3$, and $\beta_i \geqq 1$, for $1 \leqq i \leqq r$. Then

$$\phi(m) = 2^{\alpha-1} \cdot \prod_{i=1}^{r} p_i^{\beta_i - 1}(p_i - 1),$$

$$= 2^{\alpha-1+r} \cdot 3^{-r} \left(\prod_{i=1}^{r} \frac{p_i^{\beta_i - 1} \cdot 3(p_i - 1)}{2} \right).$$

(i) When $r > j$, then, by Lemma 1, $w(\phi(m)) \geqq \alpha + r - 1 \geqq \alpha + j$, and $w(m) > \alpha + j$.

(ii) When $r \leqq j$, then

$$\phi(m) = 2^{\alpha+r-1} \cdot 3^{-r} \prod_{i=1}^{r} \frac{p_i^{\beta_i - 1} \cdot 3(p_i - 1)}{2}.$$

Now

$$\frac{3(p_i - 1)}{2} = \frac{2p_i + p_i - 3}{2} \geqq p_i \geqq 3.$$

Therefore $\phi(m) = 2^{\alpha+r-1} \cdot m_3$, where $m_3 > 3^{j-r}$. Hence $w(\phi(m)) > \alpha + r - 1 + j - r = \alpha + j - 1$. Hence $w(m) > \alpha + j$, which proves Lemma 2.

3. *Proof of Theorem* 1.

CASE 1. When m is even, let $m = 2 \cdot m_1$, where $m_1 > 3^j$. Then, by Lemma 2, $w(m) > j + 1$.

CASE 2. When $m > 2$, is odd, we have $\phi(m) = \phi(2m)$, and the result follows from Case 1.

4. *Proof of Theorem* 2.

CASE 1. When $m = 2 \cdot 3^j$, for some nonnegative integer j, then

$$[\log_3 (3m)] = j + 1 = w(m).$$

CASE 2. When $m \neq 2 \cdot 3^j$ for any nonnegative integer j, let $t \geqq 0$ be selected, so that

$$2 \cdot 3^{t+1} > m > 2 \cdot 3^t.$$

Then $w(m) > t + 1 > \log_3 m - \log_3 2$, i.e., $w(m) > [\log_3 m - \log_3 2] + 1$. Hence,

$$w(m) \geqq [\log_3 m - \log_3 2] + 2 \geqq [\log_3 (3m)],$$

which proves the left side of the inequality. Now choose r, a positive integer, such that $2^r < m \leqq 2^{r+1}$ then

$$w(m) \leqq r + 1 < \log_2 m + 1,$$

therefore $w(m) \leqq [\log_2 m] + 1 = [\log_2 (2m)]$, which proves the right side of the inequality. This completes the proof.

AMICABLE NUMBERS WITH OPPOSITE PARITY

A. A. GIOIA, Western Michigan University and A. M. VAIDYA, Gujarat University, Ahmedabad, India

1. Introduction. If $\sigma(n)$ denotes the sum of the positive divisors of the integer n, then n_1 and n_2 are called *amicable* if

$$\sigma(n_1) = n_2 \text{ and } \sigma(n_2) = n_1. \tag{1.1}$$

A well-known example of a pair of amicable numbers is 220 and 284. It is also known that if $n = \prod_{i=1}^{t} p_i^{a_i}$, then

$$\sigma(n) = \prod_{i=1}^{t} (1 + p_i + p_i^2 + \cdots + p_i^{a_i}). \tag{1.2}$$

Escott [1] gave a list of 290 pairs of amicable numbers. Recently Rolf [2] announced the new pair 79750, 88730. It is remarkable that in each of the 391 pairs, both numbers have the same parity. In this paper we consider necessary conditions for the existence of a pair of amicable numbers with opposite parity.

2. The first theorem introduces the notation which will be used throughout the paper.

THEOREM 2.1. *Suppose n_1 and n_2 are amicable, n_1 is even and n_2 is odd. Then $n_1 = 2^r M^2$, $r \geqq 1$, and $n_2 = N^2$, where M and N are odd integers larger than* 1.

Proof. Since n_1 and n_2 satisfy (1.1), both $\sigma(n_1)$ and $\sigma(n_2)$ are odd. But $\sigma(n)$ is odd if and only if n is a square or the double of a square; this follows directly from (1.2) since each factor of $\sigma(n)$ must be odd. Thus $n_1 = 2^r M^2$, $r \geqq 1$, M odd, and $n_2 = N^2$, N odd. From (1.1) it is obvious that $N \neq 1$.

If $M = 1$, we have $2^r - 1 = N^2$ from (1.1). If $r \geqq 2$, then $2^r - 1 \equiv 3 \pmod 4$, but $N^2 \equiv 1 \pmod 4$; also, $r = 1$ implies $N = 1$, which is impossible. Thus $M \neq 1$ and the proof is complete.

THEOREM 2.2. *If $n_1 = 2^r M^2$ and $n_2 = N^2$ are amicable numbers with opposite parity, then N must be composite.*

Proof. Suppose $M^2 = \prod_{i=1}^{t} p_i^{2\alpha_i}$, p_i odd primes, $\alpha_i > 0$, and assume N is a prime. Let a_i, b be the unique positive integers satisfying

$$2^{a_i - 1} < p_i < 2^{a_i}, \qquad i = 1, \cdots, t$$
$$2^{b-1} < N < 2^b.$$

If n_1 and n_2 are amicable then

$$(2^{r+1} - 1) \prod_{i=1}^{t} (1 + p_i + \cdots + p_i^{2\alpha_i}) = 1 + N + N^2,$$

$$(2^{r+1} - 1) \prod (1 + 2^{a_i} + \cdots + 2^{2\alpha_i a_i}) > 1 + 2^{b-1} + 2^{2(b-1)};$$

but the left side is less than $(2^{r+1}-1)\prod 2^{2\alpha_i a_i+1}$, and the right side is $2^{3(b-1)}-1 \geqq 2^{2(b-1)+1}-1$, since $b \geqq 2$. Thus,

$$(2^{r+1}-1)\prod 2^{2\alpha_i a_i+1} > 2^{2(b-1)+1}-1,$$

$$(2^{r+1}-1)\prod 2^{2\alpha_i a_i+1} \geqq 2^{2b-1},$$

$$2^r \prod 2^{2\alpha_i a_i+1} \geqq 2^{2b-1}.$$

From this it easily follows that

$$\frac{r+t+1}{2} + \sum_{i=1}^{t} \alpha_i a_i \geqq b. \tag{2.1}$$

Also, since n_1, n_2 are amicable

$$2^r \prod_{i=1}^{t} p_i^{2\alpha_i} + N^2 = 1 + N + N^2,$$

$$2^r \prod 2^{2\alpha_i(a_i-1)} \leqq 2^b$$

$$r + \sum 2\alpha_i(a_i-1) \leqq b.$$

Combining this with (2.1) gives

$$\sum_{i=1}^{t} \alpha_i a_i - 2\sum_{i=1}^{t} \alpha_i \leqq \frac{t-r+1}{2}. \tag{2.2}$$

We now consider two cases:

CASE I: $(p_i, 3)=1$, $i=1, \cdots, t$. Since $p_i \neq 3$, then $p_i \geqq 5$ and $a_i \geqq 3$, so

$$t \leqq \sum_{i=1}^{t} \alpha_i \leqq \sum \alpha_i a_i - 2\sum \alpha_i \leqq \frac{t-r+1}{2}.$$

Then $r+t \leqq 1$ which is impossible since r and t are positive integers.

CASE II: $p_1=3$. Then $a_1=2$. If $t>1$, (2.2) gives

$$\sum_{i=2}^{t} \alpha_i a_i - 2\sum_{i=2}^{t} \alpha_i \leqq \frac{t-r+1}{2}.$$

But $a_i \geqq 3 (i=2, \cdots, t)$; hence

$$t-1 \leqq \sum_{i=2}^{t} \alpha_i \leqq \frac{t-r+1}{2},$$

and $t+r \leqq 3$. Since $r>0$ and $t>1$, we have $t=2$ and $r=1$. Thus $n_1 = 2\cdot 3^{2\alpha_1} p_2^{2\alpha_2}$ and $\sigma(n_1)=\sigma(N^2)$ implies

$$3\sigma(3^{2\alpha_1} p_2^{2\alpha_2}) = 1 + N + N^2$$

from which it follows that $(N, 3)=1$. Now from $\sigma(n_1)=n_1+N^2$ we have

$$3\sigma(3^{2\alpha_1}p_2^{2\alpha_2}) = 2\cdot 3^{2\alpha_1}p^{2\alpha_2} + N^2$$

which implies $3 \mid N$. This proves $t \geqslant 1$.

With $t=1$ and $a_1=2$, equation (2.2) gives $r \leqq 2$. Assume that $r=2$. Then $n_1 = 4\cdot 3^{2\alpha}$. Condition (1.1) gives

$$7(1 + 3 + \cdots + 3^{2\alpha}) = 4\cdot 3^{2\alpha} + N^2, \text{ and} \tag{2.3}$$

$$1 + N + N^2 = 4\cdot 3^{2\alpha} + N^2. \tag{2.4}$$

Equating the expressions for N^2 obtained from (2.3) and (2.4) yields

$$7(1 + 3 + \cdots + 3^{2\alpha-1}) + 11\cdot 3^{2\alpha} = 16\cdot 3^{4\alpha} + 1.$$

But this is impossible; hence, $r=1$.

Finally, the remaining possibility that $t=r=1$ is easily dismissed. In fact this can be done without assuming that $p_1=3$ or that N is a prime. Say $n_1 = 2p^2$, prime p. Then we have $\sigma(2p^2) = 3(1+p+p^2) = 2p^2+N^2$, so

$$(p + 1)(p + 2) = (N + 1)(N - 1). \tag{2.5}$$

If $p \leqq N$, then $p+1 \leqq N+1$ and $p+2 \geqq N-1$, so that $N-3 \leqq p \leqq N$. But for any of the four possibilities $p = N-i$ $(i=0, 1, 2, 3)$, equation (2.5) gives a contradiction. If $p > N$, then $p+1 > N+1$ and $p+2 < N-1$, which is absurd. This completes the proof of Theorem 2.2; we have also proved the

COROLLARY 2.2. *If M is a prime and if N is odd, then $2M^2$ and N^2 cannot be amicable.*

Our next theorem gives necessary conditions on amicable pairs with opposite parity in case r is odd.

THEOREM 2.3. *Suppose that 2^rM^2 and N^2 are amicable with opposite parity. If r is odd, then*

(2.6) $(M, 3) = (N, 3)$, *and*

(2.7) *there exists a prime q and a positive integer γ such that $q^\gamma \| N$ and $q \equiv \gamma \equiv 1 \pmod 3$;*

if $r \equiv 3 \pmod 4$ then

(2.8) *there exists a prime p (not necessarily distinct from q) and a positive integer δ such that $p^\delta \| N$ and $2p \equiv \delta \equiv 2 \pmod 5$, and*

$$M \equiv N \equiv \frac{r+1}{4}\sigma(M^2) \equiv 0 \pmod 5. \tag{2.9}$$

Proof. Let $r = 2a-1$, $a>0$; the usual conditions for amicability give

$$(2^{2a} - 1)\sigma(M^2) = 2^{2a-1}M^2 + N^2, \text{ and} \tag{2.10}$$

$$(2^{2a} - 1)\sigma(M^2) = \sigma(N^2). \tag{2.11}$$

Since $2^{2a}-1 \equiv 0 \pmod 3$, (2.10) shows that 3 cannot divide exactly one of M, N.

This proves (2.6). From (2.11) we see that $3 \mid \sigma(N^2)$, so $\sigma(N^2)$ contains a factor $1+q+\cdots+q^{2\gamma}$ which is divisible by 3. Evidently $q \not\equiv 0 \pmod 3$. If $q \equiv 1 \pmod 3$, then $1+q+\cdots+q^{2\gamma} \equiv 1+1+\cdots+1 = 2\gamma+1 \equiv 0 \pmod 3$, and $\gamma \equiv 1 \pmod 3$. If $q \equiv 2 \pmod 3$, then $1+q+\cdots+q^{2\gamma} \equiv 1+(2+1)+\cdots+(2+1) \not\equiv 0$. This proves (2.7).

If $r = 4b-1$ and $b > 0$ then

$$(2^{4b}-1)\sigma(M^2) = 2^{4b-1}M^2 + N^2, \text{ and} \tag{2.12}$$

$$(2^{4b}-1)\sigma(M^2) = \sigma(N^2). \tag{2.13}$$

Now $2^{4b}-1 \equiv 0 \pmod 5$; from (2.12) we see that either both of M and N are divisible by 5 or neither is. Suppose that $M \not\equiv 0 \pmod 5$ and $N \not\equiv 0 \pmod 5$. Then M^2 is either 1 or 4 (mod 5) and similarly for N^2. Also $2^{4b-1} \equiv 3 \pmod 5$. Thus, the right side of (2.12) cannot be 0 (mod 5), while the left side is always 0 (mod 5). Hence

$$M \equiv N \equiv 0 \pmod 5. \tag{2.14}$$

Now consider equation (2.13). Since $5 \mid (2^{4b}-1)$, there is a prime p such that $1+p+\cdots+p^{2\delta}$ is a factor of $\sigma(N^2)$ and this factor is divisible by 5. Clearly $p \equiv 1$ and $\delta \equiv 2 \pmod 5$ is the only solution of

$$1 + p + \cdots + p^{2\delta} \equiv 0 \pmod 5,$$

which proves (2.8).

To complete the proof of (2.9), assume $\sigma(M^2) \not\equiv 0 \pmod 5$. By (2.14) and (2.12) we have $2^{4b}-1 \equiv 0 \pmod{25}$. Now

$$\begin{aligned} 0 \equiv 2^{4b} - 1 &\equiv (1-10)^b - 1 \pmod{25} \\ &= \sum_{j=0}^{b} \binom{b}{j} (-10)^j - 1 \equiv -10b \pmod{25}. \end{aligned}$$

From this we see that $b \equiv 0 \pmod 5$; but $b = (r+1)/4$ and the proof is complete.

3. Let $t(n)$ denote the number of positive divisors of n. It is easy to see that

$$\sigma(n^2) - t(n^2) \equiv n - 1 \pmod 4, \quad \text{if } n \text{ is odd.} \tag{3.1}$$

For, if n is odd and $d \mid n$, then d is odd and $d^2 \equiv n^2 \equiv 1 \pmod 4$. Hence $d \equiv n^2/d \pmod 4$ and so $d + (n^2/d) \equiv 2 \pmod 4$. Summing over $d \mid n^2$, $d < n$ gives $\sigma(n^2) - n \equiv t(n^2) - 1$, which evidently proves (3.1). An immediate consequence of (3.1) is given in the following

THEOREM 3.1. *Suppose $n_1 = 2^r M^2$ and $n_2 = N^2$ are amicable, where $r \geqq 1$, M and N are odd. If $r = 1$, then N cannot be a square; if $r > 1$, then M is neither a square nor a prime of the type $4k+3$.*

Proof. If $r = 1$, (1.1) shows that $\sigma(N^2) \equiv 3 \pmod 4$, and from (3.1) we have $t(N^2) \equiv -N \pmod 4$. If $N = m^2$, $m = \prod p^{\delta}$, then $N^2 = \prod p^{4\delta}$ and $t(N^2)$

$= \prod(4\delta+1) \equiv 1 \pmod 4$, but $-N = -m^2 \equiv 3 \pmod 4$. Hence N cannot be a square.

If $r>1$, (1.1) shows that $\sigma(M^2) \equiv 3 \pmod 4$. Then (3.1) gives $t(M^2) \equiv -M \pmod 4$. As above, M cannot be a square; also if M is a prime of the type $4k+3$, then $t(M^2)=3$, but $-M \equiv 1 \pmod 4$. The proof is complete.

In some cases we can extend the above results to show that M is composite. For example, if $r \equiv 3 \pmod 4$ and M is prime, by Theorem 2.3 we must have $M=5$. But then

$$(2^{r+1}-1)\sigma(5^2) = 2^r 5^2 + N^2$$

yields $N^2 = 2^r(37) - 31$. This says that -31 is a quadratic residue of 37, which is a contradiction. Hence if $r \equiv 3 \pmod 4$, then M is composite.

The first author's work was supported in part by Texas Technological College Research Grant No. 191–4735.

A THEOREM ON ARBITRARY FUNCTIONS

SEYMOUR HABER, National Bureau of Standards, Washington, D.C.

A well-known theorem states that an "arbitrary" real function—that is, a function f such that $f(x)$ is a real number for each real x, with no further conditions—can have at most enumerably many strict maxima [1]. (A real function f is said to have a strict maximum at a point p. If there is a neighborhood N of p_0 such that $f(p) < f(p_0)$ for all $p \neq p_0$ in N.) We show here, as a consequence of this theorem, that a combination $a_1(x)b_1(y) + \cdots + a_n(x)b_n(y)$ of arbitrary real functions a_i and b_i has a certain partial continuity property.

LEMMA 1. *If $f(x)$ is defined and real for all x in E^1, then f has at most enumerably many strict maxima.*

LEMMA 2. *If f is defined and real on E^1 and for each x either $f(x)=0$ or $\lim_{x' \to x} f(x')=0$, then f is zero at all points of E^1, with at most enumerably many exceptions.*

Proof. It is sufficient to show that the set of points at which f is positive is at most enumerable; but at each such point f has a strict maximum, and the result follows from Lemma 1.

LEMMA 3. *If $f(x, y) = a_1(x)b_1(y) + \cdots + a_n(x)b_n(y)$, then for any numbers $x_1, x_2, \cdots, x_{n+1}$ and $y_1, y_2, \cdots, y_{n+1}$, the matrix (a_{ij}) with $a_{ij} = f(x_i, y_j)$ is singular.*

For, this $(n+1)\times(n+1)$ matrix is the sum of n matrices $(a_k(x_i)b_k(y_j))$, each of which is of rank at most one, so that its rank is at most n.

THEOREM. *Let* $f(x, y)=a_1(x)b_1(y)+\cdots+a_n(x)b_n(y)$, *and let* D *be the set of points* (x, x) *in the plane. If* g *is a function defined and continuous on* D, *and for each point* $p_0\in D, f(p)\to g(p_0)$ *as* p *approaches* p_0 *through the complement of* D, *then* $f(p)=g(p)$ *at all points of* D *except possibly for a set which is at most enumerable.*

Proof. We first consider the case in which g is identically zero on D. For each positive integer k let S_k be the set of all real numbers x such that $|a_i(x)|>k$ or $|b_i(x)|>k$ for some i. For $i=1, 2, \cdots, n$ let $a_{i,k}(x)$ be equal to $a_i(x)$ for $x\notin S_k$, and equal to zero on S_k; define $b_{i,k}$ similarly, and set $f_k(x, y)=\sum_{i=1}^{n}a_{i,k}(x)b_{i,k}(y)$. If $p_1=(x_1, y_1)\in D$ and $p\to p_1$ through the complement of D, then $f_k(p)\to 0$ just as does $f(p)$, since at each point p in E^2, $f_k(p)$ is equal either to $f(p)$ or to zero. Now let $x_2, x_3, \cdots, x_{n+1}$ be numbers distinct from each other and from x_1, and let $y_i=x_i (i=1, \cdots, n+1)$, and set $a_{i,j}=f_k(x_i, y_j)$. Letting $x_2, \cdots, x_{n+1}$ approach x_1, we see that the points (x_i, y_j) all approach p_1. For $i\neq j$ these points lie in the complement of D, and so the off-diagonal entries of the matrix $(a_{i,j})$ approach zero. Since f_k is bounded, it follows that all terms of the determinant of $(a_{i,j})$, other than the single term which is the product of the diagonal entries, go to zero. However, by Lemma 3, the determinant of $(a_{i,j})$ is itself zero, and so the product

$$f_k(x_1, x_1)\cdot f_k(x_2, x_2)\cdots f_k(x_{n+1}, x_{n+1})$$

goes to zero.

Set $h(x)=f_k(x, x)$. We have shown that, for every real x_1,

$$h(x_1)\cdot h(x_2)\cdots h(x_{n+1})\to 0$$

as the distinct numbers $x_2, \cdots, x_{n+1}$ approach x_1. This implies that h satisfies the hypotheses of Lemma 2. For if there were an x_1 such that $h(x_1)=a>0$ and $h(x)$ does not approach zero as $x\to x_1$, there would be an $\epsilon>0$ such that in every neighborhood of x_1 there would be at least one point at which $|h(x)|>\epsilon$. By the usual reasoning, there would then be infinitely many such points in each neighborhood of x_1, and, taking n of them as $x_2, x_3, \cdots, x_{n+1}$, we would have

$$|h(x_1)\cdot h(x_2)\cdots h(x_{n+1})|>\epsilon^n a.$$

It now follows from Lemma 2 that $f_k(x, x)=0$ for all, except at most enumerably many, real numbers x. Call the set of exceptional numbers T_k. Then $f(x, x)=0$ unless $x\in T_k\cup S_k$, for each positive integer k. The set of x for which $f(x, x)\neq 0$ is thus contained in $\bigcap_{k=1}^{\infty}(T_k\cup S_k)$, and so in $(\bigcup_{k=1}^{\infty}T_k)\cup(\bigcap_{k=1}^{\infty}S_k)$. The second of these last two sets is void, since if $x_0\in\bigcap_{k=1}^{\infty}S_k$, then for each positive integer k some one of the a_i and b_i takes on a value greater than k at x_0. Since there are only finitely many a_i and b_i, there must be one of them (call it c) such that $|c(x_0)|>k$ for infinitely many k; which is impossible. $\bigcup_{k=1}^{\infty}T_k$ is at most enumerable, so the theorem is proved for the case of g identically zero on D.

For general g, we apply this result to the function $F(x, y)=f(x, y)-g(x, x)$.

REMARKS. (a) The set D could be taken to be any subset of the plane having the property that each point of D has a neighborhood N such that $D \cap N$ meets each horizontal line and each vertical line at most once.

(b) These results hold, more generally, whenever the a_i and b_i are real valued functions on a space X with a countable base. The proof is the same.

SOME REMARKS ON TRANSFORMATION GROUPS AND SEMIGROUPS

W. J. GRAY, University of Alabama

In this note we establish some elementary properties of compact connected semigroups with cut points. Our results lead to a simplified proof of a theorem of Faucett. We indicate the analogues of our results in topological transformation groups.

THEOREM 1. *Let S be a compact connected Hausdorff semigroup and e be a left (right) identity of S. If G denotes the maximal connected subgroup of S containing e, then $Gx = x$ ($xG = x$) for every cut point $x \in S$.*

Proof. Let e be a right identity. Now G is compact, and if $g \in G$, the correspondence $x \to xg$ is a homeomorphism. Let z be a cut point of S. Then

$$S - z = U \cup V, \qquad U \neq \varnothing, \qquad V \neq \varnothing, \qquad U \cap V = \varnothing,$$

where U and V are open in S. Let x_1 and x_2 be noncut points of S contained in U and V, respectively (cf. [4]) and set $A = x_1G$, $B = x_2G$, $C = zG$. Then A and B are connected sets consisting of noncut points of S, and each point of C is a cut point which separates A and B in S.

If x and y are two points of C, let $x \leqq y$ if $x = y$ or $S - \{y\} = U' \cup V'$, where $A \cup \{x\} \subset U'$ and $B \subset V'$, where U' and V' are separated in S. $\leqq$ satisfies the axioms of a partial order, and is linear on C. Furthermore, the intersection of the closed set $U' \cup \{y\}$ with the closed set C is the set

$$\{q;\ q \in C \text{ and } q \leqq y\}. \tag{1}$$

Since C is linearly ordered by $\leqq$, the collection of all sets of the form (1) have the finite intersection property so that C contains a least element m. Since $CG = C$, G acts as a group of order preserving homeomorphisms on C and hence $mG = m$. Thus $m = z$. Likewise, if e is a left identity, $Gz = z$.

COROLLARY 1. *If S is a clan, let G be the identity component of the maximal subgroup of S which contains the identity. Then $xG = x = Gx$ for every cut point $x \in S$.*

COROLLARY 2. *If S is a clan, let $H(e)$ denote the maximal subgroup of S which contains the identity e, and C be the set of cut points of S. Either $\overline{C}\cap H(e)=\varnothing$ or else $H(e)$ is a totally disconnected subset of the boundary of C.*

Proof. Assume that $\overline{C}\cap H(e)\neq\varnothing$. By Theorems 1 and 4 of [3], $C\cap H(e)\neq\varnothing$ and evidently $H(e)\subset C$. Thus if G is the identity component of $H(e)$, then $tG=t=Gt$ for every $t\in H(e)$ and G must consist of e alone.

COROLLARY 3. *If S is a compact connected Hausdorff semigroup which contains a cut point and no proper left ideal, then multiplication is trivial, i.e., if $x, y\in S$, $xy=x$, and S is isomorphic to the set of constant functions from S to itself. The right dual of this corollary holds.*

Proof. By [1], S is the union of its minimal right ideals, and each minimal right ideal is a group. Let R be a minimal right ideal and e be the identity of R. Then e is a right identity of S. Hence $zR=z$ for a cut point $z\in S$. Since $Sz=S$ we have $xR=x$ for every $x\in S$. Thus R consists of e alone, and $eS=e$.

COROLLARY 4. *If S is a compact connected Hausdorff semigroup and L is a minimal left ideal of S, then if L is separated by one of its points, each element of L is an idempotent of S. The right dual of this corollary holds.*

Proof. L satisfies the hypothesis of Corollary 3, hence multiplication is trivial on L and $x^2=x$ for every $x\in L$.

THEOREM (Faucett [2]). *Let S be a compact connected Hausdorff semigroup, and K be the minimal ideal of S. If K is separated by one of its points, exactly one of the following must occur:*

(i) *K is a minimal left ideal of S and each of its elements is a right zero of S.*

(ii) *K is a minimal right ideal of S and each of its elements is a left zero of S.*

Proof. Assume K is not a minimal right ideal of S. Let R be a minimal right ideal containing a cut point z of K, and $K-\{z\}=U\cup V$, where U and V are disjoint nonempty open subsets of K. If R_1 is any other minimal right ideal, then R_1 is connected and disjoint from R, hence must lie in, say V. If L is a minimal left ideal and $L\cap U\neq\varnothing$, then L must intersect R_1, hence L is separated by z. Then by Corollary 4, the group $R\cap L$ must be trivial. Since minimal left ideals are disjoint, we also must have $U\cup\{z\}\subset L$, hence $R\subset V\cup\{z\}$. Then U must contain a minimal right ideal R_2, so that no minimal left ideal other than L can intersect R_2. Hence $K=L$, and by Corollary 4, each minimal right ideal of S is trivial (because it is a group). Thus if $x\in K$, we have $xS=x$, and (i) holds. (ii) will result if we assume that K is not a minimal left ideal of S.

Theorem 1 has an analogy in topological transformation groups. In fact,

THEOREM 2. *If (S, G, π) is a transformation group, where S is a Hausdorff continuum and G is a compact connected group, then G leaves every cut point of S fixed.*

THEOREM 3. *If (S, G, π) is a transformation group, where S is a locally connected Hausdorff continuum with a cut point, and G is a connected group, then G has a fixed point.*

Proof. In the proof of Theorem 1, replace C by the set

$$Q = \cap \{S(a, b);\ \ a \in A \text{ and } b \in B\},$$

where $S(a, b) = \{a, b\} \cup \{x;\ x \text{ separates } a \text{ and } b \text{ in } S\}$. Q is invariant under G and $Q \neq \varnothing$ since $z \in Q$. Further, Q is closed since S is locally connected. If no point of $A \cup B$ is fixed under G, then Q consists of cut points only, so that we may complete the proof as in Theorem 1.

A COMMENT ON A RECENT NOTE ON THE FAREY SERIES

ALAN ZAME, University of Miami

In a recent note Jean Blake [1] proves the following two theorems:

THEOREM 1. *The sums of the numerators of the fractions of a Farey series F_n of order n is equal to one-half the sum of the denominators of these fractions.*

THEOREM 2. *In F_n the denominator of the immediate predecessor and immediate successor of one-half is the greatest odd integer $\leqq n$.*

The proofs in the reference seem much too long. To prove the first, note that

$$\sum_{\substack{d \leqq n \\ (d,n)=1}} d = \tfrac{1}{2} n \phi(n),$$

so that the sum of the numerators corresponding to a denominator k is just $\frac{1}{2}k\phi(k)$, which is just one half of the sum of these denominators. To prove the second part, just notice that the appropriate fractions are given by $\frac{1}{2} \pm 1/2n$ if n is odd and $\frac{1}{2} \pm 1/(2n-2)$ if n is even: these are readily seen to be in the sequence F_n and are clearly the terms in that sequence nearest to $\frac{1}{2}$.

A SUM OF FRACTIONAL PARTS

K. S. WILLIAMS, University of Manchester, England

Let L denote the set of points $x=(x_1, \cdots, x_n)$ with integral coordinates in Euclidean n-space. For any prime $p\geqq 3$, let $C=C(p)$ be the set of points of L in the cube $0\leqq x_i<p$ $(i=1, 2, \cdots, n)$. Suppose that $f(x)$ is any polynomial of degree d in $x_1, \cdots, x_n$ with integral coefficients, which does not vanish identically (mod p). We let $\{a\}$ denote the fractional part of the real number a and consider the problem of estimating

$$\sum_{x\in C}\{f(x)/p\}$$

for large primes p. When $d=1$ this sum is just $\frac{1}{2}(p-1)p^{n-1}=\frac{1}{2}p^n+O(p^{n-1})$. For $d>1$ we prove, using a result of Uchiyama [1], the following theorem.

THEOREM 1.

$$\sum_{x\in C}\{f(x)/p\} = \tfrac{1}{2}p^n + O(p^{n-1/2}\log p), \tag{1}$$

as $p\to\infty$, where the constant implied in the O-symbol depends only upon n and d.

Proof.

$$\sum_{x\in C}\{f(x)/p\} = \sum_{r=0}^{p-1}\sum_{\substack{x\in C\\ f(x)\equiv r \pmod p}}\{r/p\} = 1/p\sum_{r=0}^{p-1} r\sum_{\substack{x\in C\\ f(x)\equiv r \pmod p}} 1. \tag{2}$$

Now let $e(t)$ denote $\exp(2\pi i t p^{-1})$ for any real t. Then as

$$(1/p)\sum_{v=0}^{p-1} e(av) = \begin{cases} 1 & \text{if } a\equiv 0 \pmod p \\ 0 & \text{if } a\not\equiv 0 \pmod p \end{cases}$$

we have

$$\begin{aligned}\sum_{x\in C}\{f(x)/p\} &= (1/p^2)\sum_{r=0}^{p-1} r\sum_{x\in C}\sum_{v=0}^{p-1} e(v(f(x)-r)) \\ &= (1/p^2)\sum_{v=0}^{p-1}\sum_{x\in C} e(vf(x))\sum_{r=0}^{p-1} re(-rv).\end{aligned}$$

The term corresponding to $v=0$ is just

$$(1/p^2)\sum_{x\in C}\sum_{r=0}^{p-1} r = \tfrac{1}{2}(p-1)p^{n-1}.$$

For $v\not\equiv 0$ we have

$$\sum_{r=0}^{p-1} re(-rv) = -p/(1-e(-v)),$$

whence

$$\left|\sum_{x\in C}\{f(x)/p\} - \tfrac{1}{2}p^{n-1}(p-1)\right| = \left|(1/p)\sum_{v=1}^{p-1} 1/(1-e(-v))\sum_{x\in C} e(vf(x))\right|$$

$$\leqq (1/p)\sum_{v=1}^{p-1} 1/\left|1-e(-v)\right|\left|\sum_{x\in C} e(vf(x))\right|.$$

By a recent result of Uchiyama [1]

$$\left|\sum_{x\in C} e(vf(x))\right| \leqq kp^{n-1/2}$$

where the constant k depends only upon n and d. Hence we have

$$\left|\sum_{x\in C}\left\{\frac{f(x)}{p}\right\} - \frac{1}{2}p^{n-1}(p-1)\right| \leqq \frac{k}{2}p^{n-3/2}\sum_{v=1}^{p-1}\frac{1}{\sin(\pi v/p)},$$

from which the theorem follows in view of the well-known result

$$\sum_{v=1}^{p-1}\frac{1}{\sin(\pi v/p)} \leqq p\sum_{v=1}^{(p-1)/2}\frac{1}{v} \leqq p\log p.$$

We now show that the error term in (1) can be improved for polynomials $f(x)$ of certain special types, namely diagonal and quadratic polynomials.

THEOREM 2. *If* $f(x)=a_1x_1^{k_1}+\cdots+a_nx_n^{k_n}+a_0$, *where each* $k_i\geqq 1$ *and* $p\nmid a_1\cdots a_n$, *then, provided* $n\geqq 3$,

$$\sum_{x\in C}\{f(x)/p\} = (p^n/2) + O(p^{n-1}),$$

as $p\to\infty$, *where the constant implied in the O-symbol depends only upon* $k_1, \cdots, k_n$.

THEOREM 3. *Let* $f(x_1, x_2)$ *be a quadratic polynomial which is not a function of only one integral variable and which has a discriminant not divisible by* p. *Suppose further that the discriminant of* $f_1(x_1, x_2, 0)$ *is also not divisible by* p, *where* $f_1(x_1, x_2, x_3)\equiv x_3^2 f(x_1/x_3, x_2/x_3)$. *Then*

$$\sum_{x_1=0}^{p-1}\sum_{x_2=0}^{p-1}\{f(x_1, x_2)/p\} = \tfrac{1}{2}p^2 + O(p),$$

as $p\to\infty$.

Proof of Theorem 2. By (2)

$$\sum_{x\in C}\{f(x)/p\} = (1/p)\sum_{r=1}^{p-1} rN_r, \tag{3}$$

where N_r denotes the number of $x\in C$ with $f(x)\equiv r \pmod p$. Weil has shown [2] that

$$N_r = p^{n-1} + O(p^{n/2}),$$

as $p \to \infty$, where the constant in the O-symbol depends only on $k_1, \cdots, k_n$. The theorem follows at once.

Proof of Theorem 3. As is well known, under the conditions stated in the theorem, we may reduce $f(x_1, x_2)$ by a linear nonsingular transformation (mod p) to the canonical form

$$ay_1^2 + by_2^2 + c \qquad (p \nmid abc).$$

This transformation will not affect the sum under consideration and so we need only consider

$$\sum_{y_1=0}^{p-1} \sum_{y_2=0}^{p-1} \left\{\frac{ay_1^2 + by_2^2 + c}{p}\right\} \qquad (p \nmid abc).$$

The theorem then follows from (3), as in this case

$$N_r = \begin{cases} p - (-ab/p) & \text{if } r \not\equiv c \\ p + (p-1)(-ab/p) & \text{if } r \equiv c. \end{cases}$$

CONJECTURE: (1) may be replaced by

$$\sum_{x \in C} \{f(x)/p\} = \tfrac{1}{2}p^n + O(p^{n-1/2}), \quad \text{as } p \to \infty. \tag{1'}$$

TAYLOR'S FORMULA AND THE EXISTENCE OF nTH DERIVATIVES

P. R. BEESACK, Carleton University, Ottawa

A common form of Taylor's theorem states sufficient conditions for a function f to have an expansion of the form

$$f(a+h) = a_0 + a_1 h + a_2 h^2 + \cdots + a_{n-1}h^{n-1} + R_n(h), \tag{1}$$

valid in some one- or two-sided neighborhood of $h=0$, the remainder term R_n involving a factor of the form $f^{(n)}(X)$, where X is strictly between a and $a+h$. The existence (finite or infinite) of $f^{(n)}$ *throughout* at least some deleted neighborhood (or one-sided neighborhood) of a obviously must be postulated in order to prove any theorem of this kind. On the other hand, $f^{(n)}(a)$ need not exist for the validity of such an expansion.

A less well-known form of Taylor's theorem is that due to de la Vallée Poussin [1, pp. 78–80], which we state here in the following form:

If $f^{(n)}(a)$ exists, and if the function M_n is defined in a suitable deleted neighborhood, $\mathring{N}(0)$, by

$$(2)\quad f(a+h) = f(a) + f'(a)h + \frac{f''(a)}{2!}h^2 + \cdots + \frac{f^{(n-1)}(a)}{(n-1)!}h^{n-1} + M_n(h)h^n,$$

then $\lim_{h\to 0} M_n(h) = f^{(n)}(a)/n!$.

This result is valid whether $f^{(n)}(a)$ is finite or properly infinite; that is provided only the limit

$$\lim_{h\to 0} \frac{f^{(n-1)}(a+h) - f^{(n-1)}(a)}{h}$$

exists, finite or infinite. In case $f^{(n)}(a)$ is finite, this result is equivalent to that given in [2], although the proofs are quite different. The theorem is also valid in case one-sided neighborhoods, and corresponding one-sided derivatives are used throughout. Moreover, in case $f^{(n)}(a)$ is finite, f has a *unique* expansion of the form (2). That is, if there are constants $a_0, a_1, \cdots, a_{n-1}$ such that

$$(3)\qquad f(a+h) = a_0 + a_1h + a_2h^2 + \cdots + a_{n-1}h^{n-1} + M_n(h)h^n,$$

where M_n is bounded in some $\mathring{N}(0)$, then $a_k = f^{(k)}(a)/k!$ for $0 \leqq k \leqq n-1$.

The purpose of this note is to find additional conditions on M_n which will ensure the existence of $f^{(n)}(a)$ in case f has an expansion of the form (3). The mere boundedness of M_n in $\mathring{N}(0)$ is clearly not sufficient even in the case $n=1$. In view of the expansion (2) of de la Vallée Poussin, one is tempted to replace the assumption that M_n is bounded in $\mathring{N}(0)$ by the assumption that $\lim_{h\to 0} M_n$ exists. Although this condition is sufficient to guarantee the existence of $f^{(n)}(a)$ in case $n=1$ (if f is assumed continuous at a), it is not sufficient for $n>1$. A simple counterexample for $n=2$ is given by the function f defined by

$$f(x) = \begin{cases} x^3 \cos(x^{-1}), & x \neq 0, \\ 0, & x = 0. \end{cases}$$

Here, $f(h) = 0 + 0\cdot h + M_2(h)h^2$ for $h \neq 0$, and

$$\lim_{h\to 0} M_2(h) = \lim_{h\to 0} h\cos(h^{-1}) = 0$$

exists, while $f''(0)$ does not exist.

Returning to the expansion (3) it is clear that if $f^{(n)}(a)$ exists, then M_n', M_n'', $\cdots$, $M_n^{(n-1)}$ must all exist throughout some $\mathring{N}(0)$. The preceding example shows, however, that even adding these conditions will not guarantee the existence of $f^{(n)}(a)$. The necessary and sufficient condition for the existence of

$f^{(n)}(a)$ (finite) is given in the following theorem. For convenience we state only the two-sided form of the theorem.

THEOREM. *If f is continuous at a, then $f^{(n)}(a)$ exists (finite)$\Leftrightarrow\exists$ constants $a_0, a_1, \cdots, a_{n-1}$ and a function M_n defined in some $\tilde{N}(0)$ such that*

$$f(a+h) = a_0 + a_1h + a_2h^2 + \cdots + a_{n-1}h^{n-1} + M_n(h)h^n, \tag{4}$$

for $h\in\tilde{N}(0)$, where $M_n^{(n-1)}$ exists in $\tilde{N}(0)$, and

$$\lim_{h\to 0} M_n(h) \text{ exists, and } \lim_{h\to 0} h^j M_n^{(j)}(h) = 0 \quad \text{for } j = 1, 2, \cdots, n-1. \tag{5}$$

Moreover, in this case, $a_0, a_1, \cdots, a_{n-1}$ and M_n are uniquely determined and $a_k = f^{(k)}(a)/k!$ for $k = 0, 1, \cdots, n-1$, while

$$\lim_{h\to 0} M_n(h) = \frac{f^{(n)}(a)}{n!}.$$

Proof. We prove both parts by induction, proving first the sufficiency of the conditions. If $n=1$ we thus assume that f is continuous at a, and that $\exists$ a constant a_0 and a function M_1 defined in a $\tilde{N}(0)$ such that $f(a+h)=a_0+M_1(h)h$, for $h\in\tilde{N}(0)$, and $\lim_{h\to 0} M_1(h)$ exists. Letting $h\to 0$, we obtain $f(a)=a_0$. Hence

$$f'(a) = \lim_{h\to 0}\frac{f(a+h)-a_0}{h} = \lim_{h\to 0} M_1(h) \text{ exists},$$

and the conditions are sufficient in the case $n=1$.

Now, suppose that the conditions are sufficient for $n=k\geqq 1$. Let f be continuous at a, and suppose that $\exists$ constants $a_0, a_1, \cdots, a_k$, and a function M_{k+1} defined in a $\tilde{N}(0)$ such that

$$f(a+h) = a_0 + a_1h + a_2h^2 + \cdots + a_kh^k + M_{k+1}(h)h^{k+1}, \quad \text{for } h \in \tilde{N}(0), \tag{6}$$

where $M_{k+1}^{(k)}$ exists in $\tilde{N}(0)$, $\lim M_{k+1}(h)=A$ exists, and

$$\lim h^j M_{k+1}^{(j)}(h) = 0 \qquad \text{for } j = 1, 2, \cdots, k.$$

Then for $h\in\tilde{N}(0)$ we obtain, by differentiating (6),

$$f'(a+h) = a_1 + 2a_2h + \cdots + (ka_k)h^{k-1} + M'_{k+1}h^{k+1} + (k+1)M_{k+1}h^k,$$

or

$$f'(a+h) = a_1 + (2a_2)h + \cdots + (ka_k)h^{k-1} + \overline{M}_k(h)h^k, \qquad \text{for } h \in \tilde{N}(0), \tag{7}$$

where $\overline{M}_k(h)\equiv hM'_{k+1}(h)+(k+1)M_{k+1}(h)$ is defined in $\tilde{N}(0)$.

We now show that the induction assumption can be applied to the function f'. First we note that $f(a)=a_0$ follows directly from (6) by letting $h\to 0$. Hence

$$f'(a) = \lim_{h\to 0}\frac{f(a+h)-a_0}{h} = \lim_{h\to 0}(a_1 + a_2h + \cdots + a_kh^{k-1} + M_{k+1}(h)h^k) = a_1;$$

moreover, by (7) it follows that $\lim f'(a+h)=a_1=f'(a)$, so that f' is continuous at a. Also,

$$h^j\overline{M}_k^{(j)}(h) = h^{j+1}M_{k+1}^{(j+1)}(h) + (k+j+1)h^jM_{k+1}^{(j)}(h) \to 0$$

as $h\to 0$ for $j=1, 2, \cdots, (k-1)$ by the hypotheses on M_{k+1}, and similarly, $\lim \overline{M}_k(h)=0+(k+1)A$ exists.

Hence the induction assumption applies to f' as given by (7). It follows that $(f')^{(k)}(a)=f^{(k+1)}(a)$ exists, and that

$$ma_m = \frac{f^{(m)}(a)}{(m-1)!} \qquad \text{for } m = 1, 2, \cdots, k,$$

$$\lim \overline{M}_k(h) = \frac{f^{(k+1)}(a)}{k!} = (k+1)A.$$

Since $a_0=f(a)$ was proved, this completes the induction and proves the sufficiency of the conditions.

To prove the necessity in the case $n=1$, we assume that $f'(a)$ exists (so that f is automatically continuous at a). We are to prove that $\exists$ a constant a_0 and a function M_1 defined in a $\tilde{N}(0)$ such that

$$f(a+h) = a_0 + M_1(h)h,$$

for $h\in\tilde{N}(0)$, and $\lim M_1(h)=f'(a)$. It clearly suffices to define $a_0=f(a)$, and to define M_1 by the equation $f(a+h)=f(a)+M_1(h)h$, for $h\in\tilde{N}_\delta(0)$, where $\delta>0$ is chosen so that $f(a+h)$ is defined in $N_\delta(0)$. Such a δ exists because $f'(a)$ exists. But then

$$\lim M_1(h) = \lim \frac{f(a+h)-f(a)}{h} = f'(a) \text{ exists},$$

and the proof in the case $n=1$ is complete.

Now assume that the conditions are necessary for $n=k\geqq 1$. Suppose that $f^{(k+1)}(a)$ exists. Then $f^{(k)}$ exists in some $N_\delta(a)$ (and is even continuous at a), and $f^{(k-1)}, \cdots, f', f$ are all continuous in $N_\delta(a)$. In particular, the constants $a_0=f(a), \cdots, a_k=f^{(k)}(a)/k!$ are all defined, and so is the function M_{k+1} defined in $\tilde{N}_\delta(0)$ by the equation

$$f(a+h) = f(a) + f'(a)h + \cdots + \frac{f^{(k)}(a)}{k!}h^k + M_{k+1}(h)h^{k+1}. \tag{8}$$

Clearly $M_{k+1}^{(k)}$ exists in $\tilde{N}_\delta(0)$ by (8). As in the sufficiency proof, we obtain

$$f'(a+h) = f'(a) + f''(a)h + \cdots + \frac{f^{(k)}(a)}{(k-1)!}h^{k-1} + \overline{M}_k(h)h^k, \tag{9}$$

for $h\in\tilde{N}_\delta(0)$, where $\overline{M}_k(h)\equiv hM'_{k+1}(h)+(k+1)M_{k+1}(h)$ is also defined in $\tilde{N}_\delta(0)$.

On the other hand, since $(f')^{(k)}(a)$ exists, the induction assumption applies to the function f', so $\exists$ constants $A_0, \cdots, A_{k-1}$ and a function R_k defined in some $\tilde{N}_\epsilon(0)$ such that

$$(10) \quad f'(a+h) = A_0 + A_1 h + \cdots + A_{k-1}h^{k-1} + R_k(h)h^k, \qquad h \in \tilde{N}_\epsilon(0),$$

where $R_k^{(k-1)}$ exists in $\tilde{N}_\epsilon(0)$, $\lim R_k(h)$ exists, and $\lim h^j R_k^{(j)}(h) = 0$ for $j = 1, 2, \cdots, k-1$. By the uniqueness, shown in the sufficiency part of the proof, it follows that

$$A_0 = f'(a), \qquad A_1 = \frac{f''(a)}{1!}, \cdots, A_{k-1} = \frac{f^{(k)}(a)}{(k-1)!}.$$

Hence, from comparison of (9) and (10), it also follows that $\overline{M}_k(h) = R_k(h)$ for all $h \in \tilde{N}_\gamma(0)$, where $\gamma = \min(\delta, \epsilon)$. Thus, $\lim_{h\to 0} \overline{M}_k(h) = \lim_{h\to 0} R_k(h) = B$ exists, and $\lim_{h\to 0} h^j \overline{M}_k^{(j)}(h) = 0$, $j = 1, 2, \cdots, k-1$.

To complete the induction (and the proof of the theorem) it remains only to prove that $\lim M_{k+1}(h)$ exists, and $\lim h^j M_{k+1}^{(j)}(h) = 0$ for $j = 1, 2, \cdots, k$. The first of these follows from (8) and (9), which give

$$\begin{aligned}
\lim M_{k+1}(h) &= \lim \left[f(a+h) - \left\{ f(a) + f'(a)h + \cdots + \frac{f^{(k)}(a)}{k!} h^k \right\} \right] \Big/ h^{k+1} \\
&= \frac{1}{k+1} \lim \left[f'(a+h) - \left\{ f'(a) + \cdots + \frac{f^{(k)}(a)}{(k-1)!} h^{k-1} \right\} \right] \Big/ h^k \\
&= \frac{1}{k+1} \lim \overline{M}_k(h) = \frac{B}{k+1}.
\end{aligned}$$

Using this result and the definition

$$\overline{M}_k(h) = hM'_{k+1}(h) + (k+1)M_{k+1}(h),$$

it now follows that $\lim hM'_{k+1}(h) = 0$, proving the second limit relation for $j = 1$, and any $k \geqq 1$. In particular, the induction is complete in case $k = 1$.

For $k \geqq 2$, the remaining limit relation follows for $j = 1, 2, \cdots, k-1$ by writing

$$\begin{aligned}
\lim h^j M_{k+1}^{(j)}(h) &= \lim \frac{h^{k+j+1} M_{k+1}^{(j)}(h)}{h^{k+1}} \\
&= \lim \frac{h^{k+j+1} M_{k+1}^{(j+1)}(h) + (k+j+1)h^{k+j} M_{k+1}^{(j)}(h)}{(k+1)h^k} \\
&= \frac{1}{k+1} \lim h^j \{ hM_{k+1}^{(j+1)}(h) + (k+j+1)M_{k+1}^{(j)}(h) \} \\
&= \frac{1}{k+1} \lim h^j \overline{M}_k^{(j)}(h) = 0.
\end{aligned}$$

Taking $j=k-1$ in the preceding, we have

$$\lim h^{k-1}\{hM_{k+1}^{(k)}(h) + 2kM_{k+1}^{(k-1)}(h)\} = 0,$$

and since $\lim h^{k-1}M_{k+1}^{(k-1)}(h)=0$ has been proved, it also follows that $\lim h^k M_{k+1}^{(k)}(h)=0$, completing the proof.

REMARK 1. An examination of the proof of the theorem shows that the sufficiency half of the theorem remains valid in the form "*$f^{(n)}(a)$ exists, finite or properly infinite*," provided conditions (5) are replaced by the two conditions:

(5_1) $\lim_{h\to 0} M_n(h)$ exists, finite or infinite; $\lim h^j M_n^{(j)}(h) = 0, \quad 1 \leqq j \leqq n-1;$

(5_2) $\lim_{h\to 0} hM_n(h) = 0.$

In case $\lim M_n(h)=+\infty$, then $f^{(n)}(a)=+\infty$, and similarly for $-\infty$. On the other hand (as pointed out by the referee), these conditions are *not necessary* in case $f^{(n)}(a)$ is infinite. That this is the case for each $n\geqq 1$ can be seen by the example

$$f(x) = x^{(2n-1)/2} \text{ if } x \geqq 0; \qquad f(x) = (-1)^n f(-x) \text{ if } x < 0.$$

For this function, $f(0)=f'(0)=\cdots=f^{(n-1)}(0)=0$ and $f^{(n)}(0)=+\infty$. Taking $a=0$ in (4), and $a_0=a_1=\cdots=a_{n-1}=0$, we have $M_n(h)=|h|^{-1/2}$ for $h\neq 0$. Although it is true that

$$\lim M_n(h) = +\infty, \qquad \lim hM_n(h) = 0,$$

one easily verifies that $\lim |h^j M_n^{(j)}(h)| = +\infty$ (and not 0) for $1\leqq j\leqq n-1$.

By almost the same method of proof used in proving necessity above, however, one can prove that *if $f^{(n)}(a)$ exists, finite or properly infinite* (and f is continuous at a if $n=1$, or f' is continuous at a for $n\geqq 2$) then conditions (5) of the theorem may be replaced by the two (necessary) conditions:

(5_3) $\lim_{h\to 0} M_n(h)$ *exists, finite or infinite*;

(5_4) $\lim_{h\to 0} h^{j+1} M_n^{(j)}(h) = 0, \quad 0 \leqq j \leqq n-1.$

On the other hand, that these conditions are *not sufficient* for the existence of $f^{(n)}(a)$ can be seen using the example preceding the statement of the main theorem. In this example, $n=2$ and $\lim M_2(h)=0$; whether conditions (5_3) and (5_4) are sufficient in case $\lim M_n(h)=\infty$ seems unlikely, but we have no counterexample for this case.

REMARK 2. $f^{(n)}$ exists throughout $N(a)\Leftrightarrow$the conditions stated in the theorem hold, and in addition $M_n^{(n)}$ exists in $\tilde{N}(0)$. This follows at once from the representation (4).

REMARK 3. $f^{(n)}$ is continuous at $a \Leftrightarrow$ the conditions stated in the theorem hold, and in addition,

$$(5') \qquad M_n^{(n)} \text{ exists in } \tilde{N}(0), \quad \text{and} \quad \lim h^n M_n^{(n)}(h) = 0.$$

No difficulty occurs in completing the induction steps in the proof, and the argument in the case $n=1$ is trivial, as usual.

REMARK 4. If f is a complex-valued function of a real variable, the theorem remains valid; indeed the *proof* of the sufficiency part of the theorem remains valid. The necessity (as well as the sufficiency) follows by applying the theorem separately to the real and imaginary parts of f.

Similarly, if f is a complex-valued function of a complex variable the proof of the sufficiency part of the theorem remains valid, while the necessity part of the theorem follows from the Cauchy-Taylor expansion of the function for $n>1$, and from the definition of a derivative when $n=1$.

The author thanks the referee for his helpful suggestions.

SESQUIREGULAR MEASURES

S. K. BERBERIAN, The University of Iowa

In the theory of measure in locally compact spaces, the term "regular measure" has been defined in various ways. In this note several of the commonly used definitions will be compared, and simplifications will be observed in the case of finite measures.

Throughout, X denotes a locally compact Hausdorff space. We follow the terminology of [3]. In particular a weakly Borel measure ρ is said to be *inner regular* if

$$(1) \qquad \rho(A) = \text{LUB}\,\{\rho(C): C \subset A,\ C \text{ compact}\}$$

for all weakly Borel sets A, *outer regular* if

$$(2) \qquad \rho(A) = \text{GLB}\,\{\rho(U): U \supset A,\ U \text{ open}\}$$

for all weakly Borel sets A, and *biregular* if it is both inner and outer regular. If a weakly Borel measure is either inner regular or outer regular, its restriction to the class of Borel sets is a regular Borel measure (see [5, p. 228, Theorem F] or [1, p. 199, Theorem 5]; the only delicate point is that if $C \subset U$, where C is compact and U is open, then there exists an open Borel set V such that $C \subset V \subset U$ [5, p. 219, Theorem A]).

A weakly Borel measure τ will be called *sesquiregular* if it is outer regular, and if

$$\tau(U) = \text{LUB}\{\tau(C): C \subset U, C \text{ compact}\} \tag{3}$$

for all open sets U. Sesquiregular measures occur in the theory of integration developed in Hewitt-Ross [7, p. 123]; the main aim of this note is to exhibit the simple relation between sesquiregularity and inner regularity.

THEOREM 1. *If τ is a sesquiregular weakly Borel measure on X, there exists one and only one inner regular weakly Borel measure ρ on X such that $\rho(E) = \tau(E)$ for all Borel sets E. Specifically,*

$$\rho(A) = \text{LUB}\{\tau(C): C \subset A, C \text{ compact}\} \tag{4}$$

for all weakly Borel sets A.

Proof. Since the restriction of τ to the class of Borel sets is a regular Borel measure, formula (4) defines an inner regular weakly Borel measure ρ [2, Theorem 2]. As to uniqueness, it is obvious that any two inner regular weakly Borel measures that agree on compact sets are identical (in fact, agreement on compact G_δ's is sufficient [1, p. 200, Theorem 1]).

Conversely, it is shown in the next theorem that each inner regular ρ determines a unique sesquiregular τ.

LEMMA 1. *Let ρ be an inner regular weakly Borel measure. If A_0 is a weakly Borel set such that $A_0 \subset U_0$ for some open set U_0 of finite measure, then*

$$\rho(A_0) = \text{GLB}\{\rho(U): U \supset A_0, U \text{ open}\}.$$

Proof. If C_n is a sequence of compact subsets of $U_0 - A_0$ whose measure approximates that of $U_0 - A_0$, then $U_0 - C_n$ is a sequence of open supersets of A_0 whose measure approximates that of A_0.

THEOREM 2. *If ρ is an inner regular weakly Borel measure on X, there exists one and only one sesquiregular weakly Borel measure τ on X such that $\tau(E) = \rho(E)$ for all Borel sets E. Specifically,*

$$\tau(A) = \text{GLB}\{\rho(U): U \supset A, U \text{ open}\} \tag{5}$$

for all weakly Borel sets A.

Proof. It is routine to verify that the set function τ defined by (5) is monotone and countably subadditive, that it agrees with ρ on open sets and Borel

sets [5, p. 228, Theorem F], and that it satisfies the conditions (2) and (3). The proof that τ is additive can be reduced to the observation that $\tau(A)=\rho(A)$ whenever $\tau(A)$ is finite (Lemma 1). This proves existence. It is easy to see that a sesquiregular weakly Borel measure is uniquely determined by its values on Borel sets (or merely on compact G_δ's).

The sesquiregular analogue of [2, Theorem 2] is as follows (cf. [6]):

COROLLARY. *If μ is a regular Borel measure on X, there exists one and only one sesquiregular weakly Borel measure τ that extends μ.*

Proof. Let ρ be the unique inner regular weakly Borel extension of μ [2, Theorem 2], and define τ as in Theorem 2.

For finite measures, the concepts of inner regularity and sesquiregularity coincide, as we shall see in the next theorem.

LEMMA 2. *Suppose ρ_1 and ρ_2 are weakly Borel measures on X such that $\rho_1(C)=\rho_2(C)$ for all compact sets C. Assume that for each $i=1, 2$ there exists a Borel set E_i such that $\rho_i(X-E_i)=0$. Then $\rho_1=\rho_2$.*

Proof. We note first that ρ_1 and ρ_2 agree on Borel sets [1, p. 185, Theorem 3]. Define $E=E_1\cup E_2$. If A is any weakly Borel set, clearly $\rho_1(A-E)=\rho_2(A-E)=0$; since $A\cap E$ is a Borel set [1, p. 181, Theorem 2], we have also $\rho_1(A\cap E)=\rho_2(A\cap E)$, and therefore $\rho_1(A)=\rho_2(A)$.

THEOREM 3. *If ρ is a finite measure on the weakly Borel sets of X, the following conditions are equivalent:*

(a) *ρ is inner regular,*

(b) *ρ is biregular,*

(c) *ρ is sesquiregular,*

(d) *ρ is outer regular, and there exists a Borel set E such that $\rho(X-E)=0$.*

Proof. By Lemma 1, (a) implies (b). It is trivial that (b) implies (c).

(c) implies (d): By (3) there is a sequence of compact sets C_n such that $\rho(X)$ is the least upper bound of the $\rho(C_n)$. The union of the C_n is a Borel set E such that $\rho(E)=\rho(X)$, and so $\rho(X-E)=0$ by finiteness.

(d) implies (a): The restriction of ρ to the class of Borel sets is a regular Borel measure μ. Let ρ' be the inner regular weakly Borel extension of μ; to prove that ρ is inner regular, it will suffice to show that $\rho=\rho'$. Since μ is bounded, it follows that ρ' is finite; by the argument in the preceding paragraph, there exists a Borel set E' such that $\rho'(X-E')=0$. Since ρ and ρ' agree on Borel sets, $\rho=\rho'$ by Lemma 2.

The analogue of Lemma 1 for sesquiregular measures is as follows [7, p. 126, Theorem 11.32]:

COROLLARY. *If τ is a sesquiregular weakly Borel measure, and A_0 is a weakly Borel set of finite measure, then*

$$\tau(A_0) = \mathrm{LUB}\{\tau(C): \quad C \subset A_0,\ C \text{ compact}\}.$$

Proof. Choose any open set U_0 such that $U_0 \supset A_0$ and $\tau(U_0)$ is finite (τ is outer regular); let E_0 be a Borel set such that $E_0 \subset U_0$ and $\tau(U_0 - E_0) = 0$ (see the proof of Theorem 3). The formula $\tau'(A) = \tau(A \cap U_0)$ defines a finite weakly Borel measure τ' that is obviously outer regular. Since $\tau'(X - E_0) = \tau(U_0 - E_0) = 0$, it follows from criterion (d) of Theorem 3 that τ' is inner regular; the conclusion of the corollary follows on applying (1) to τ' and A_0.

REMARKS. 1. If X is not σ-compact, there exists a nonzero outer regular weakly Borel measure on X that vanishes for all Borel sets [2, p. 417], and is therefore not sesquiregular.

2. An inner regular measure need not be sesquiregular. For example if G is a locally compact group which is neither discrete nor σ-compact, and if ρ is the inner regular Haar measure on the weakly Borel sets of G, then ρ is not outer regular [3, Theorem 1].

3. A sesquiregular measure need not be inner regular. For example, let G and ρ be as in Remark 2, and let τ be the sesquiregular Haar measure on the weakly Borel sets of G defined as in Theorem 2. Since ρ is not outer regular, it cannot be proportional to τ; hence τ cannot be inner regular (if it were, it would be proportional to ρ [2, Theorem 3]).

4. Let ν be a finite Baire measure on X, and let f be any bounded continuous function on X. Even though f may not be a Baire function, the "integral of f with respect to ν" may be defined as follows: (i) choose a Baire set F such that $\nu = \nu_F$ [1, p. 154, Theorem 2], (ii) observe that $\chi_F f$ is a bounded Baire function [1, p. 182, Exercise 13, and p. 48, Exercise 2], and (iii) define $\int f d\nu$ to be $\int \chi_F f d\nu$ [1, p. 125, Lemma 4].

For example, if G is a locally compact abelian group with character group X, a well-known representation theorem may be stated as follows: *A continuous positive definite function on G is the Fourier-Stieltjes transform of one and only one finite biregular weakly Borel measure on X* [8, p. 19, Theorem 1.4.3, and p.17, Theorem 1.3.6]. In view of the preceding paragraph, and the theorems of this note (especially Theorem 3), the representation theorem remains correct with "biregular weakly Borel measure" replaced by "Baire measure" or "regular Borel measure" or "inner regular weakly Borel measure" or "sesquiregular weakly Borel measure."

5. The validity of "(a) implies (b)" in Theorem 3 reveals an error in [4]; a "regular weakly Borel *PO*-measure" is indeed biregular, contrary to the assertion in [4, p. 88, Example 4]. The erroneous assertion can simply be excised; it is used nowhere in [4].

A NEW PROOF OF LEBESGUE'S COVERING LEMMA

JOHN HUNT, University of Virginia

Introduction. Lebesgue's covering lemma states that, given an open covering $U_1, \cdots, U_n$ of a compact metric space X, ρ, there is a positive number δ such that if $\rho(x, y) < \delta$ then both x and y belong to some U_i. The purpose of this short note is to enlarge upon this conclusion and thereby provide a more interesting proof of the lemma than the usual ones.

We first explain how we arrive at the new result. Figure 1 shows a compact metric space covered by two open subsets U and V. If δ is the distance between $U - V$ and $V - U$, then any two points whose distance apart is less than δ both lie in U or V; further, no number greater than δ will ensure this. Figure 2 shows a compact metric space X, ρ covered by a finite number of open subsets $U_1, \cdots, U_n$ and one may suspect that the same idea holds. The lines of the figure divide the set X up into a number of "compartments" (those white bits crossed by no lines) and by analogy one may suspect that two of these compartments A and B, at a positive distance apart, have the properties

(i) if $\rho(x, y) < \rho(A, B)$ then both x and y belong to some U_i,

(ii) no number greater than $\rho(A, B)$ has this property. Except in a trivial case this is so, and it is the extension of Lebesgue's lemma that we shall prove.

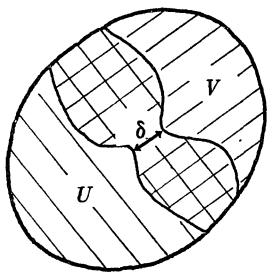

FIG. 1

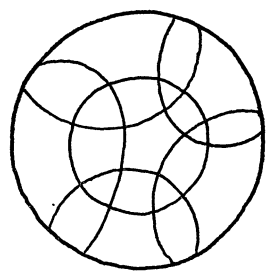

FIG. 2

The trivial exception. When each pair of points is contained in some U_i, no pair of compartments satisfies (ii), because every positive number satisfies (i). In this case, however, Lebesgue's lemma is trivial.

DEFINITION OF A COMPARTMENT. *Let X be a set covered by a finite number of subsets $X_1, \cdots, X_n$. A compartment (of the covering $X_1, \cdots, X_n$) is a nonempty set expressible as the intersection of n distinct sets, consisting of X_i's and complements of X_i's.*

It follows from the definition that the compartments of a finite covering of X form a finite, disjoint covering of X. Where no confusion arises, we simply speak of compartments, instead of compartments of a particular covering. We do this below.

THEOREM. *If $U_1, \cdots, U_n$ is an open covering of a compact metric space X, ρ, and some pair of points is contained in no U_i, then there are two compartments A and B, a positive distance apart, such that*

(i) *if $\rho(x, y) < \rho(A, B)$ then both x and y belong to some U_i,*

(ii) *no number greater than $\rho(A, B)$ has property* (i).

Proof. The two points contained in no U_i belong to a pair of compartments contained in no U_i. Thus we may define

$$\delta = \min \rho(E, F),$$

where E and F are any compartments contained in no U_i. Then δ is attained as the distance between some pair of compartments A and B, and it satisfies the requirements of the theorem.

First, $\delta > 0$. For, let E and F be compartments such that $\rho(E, F) = 0$. Then from E and F we can select sequences $\{x_i\}$ and $\{y_i\}$ such that $\rho(x_i, y_i) \to 0$. By compactness, there is a point x and a subsequence $\{x_{N_i}\}$ of $\{x_i\}$ such that $x_{N_i} \to x$. Since $y_{N_i} \to x$ as well, x belongs to both $\overline{E}$ and $\overline{F}$. But x belongs to some open U_k. Thus U_k meets both E and F and so, by the definition of compartment, contains both E and F.

δ also satisfies (i) and (ii). For, let $\rho(x, y) < \delta$. x and y belong to compartments E and F. If $E = F$ then both x and y necessarily belong to some U_i, because each compartment is contained in some U_i. If $E \neq F$ then $\rho(E, F) < \delta$ and some U_i contains both E and F. Thus some U_i contains both x and y. On the other hand, if $\delta_1 > \delta$ then there are two compartments E and F, contained in no U_i, such that $\rho(E, F) < \delta_1$. In E and F we can select points x and y such that $\rho(x, y) < \delta_1$. Then x and y belong to no U_i since otherwise U_i would contain both E and F.

AN INTERESTING DUAL GALOIS CORRESPONDENCE

W. A. LABACH, Northwestern University

Let P and Q be complete lattices and let $\sigma: P \to Q$ and $\tau: Q \to P$ be isotone (i.e., order preserving) mappings. Define for $x \in P$, $\bar{x} = x^{\sigma\tau}$ and for $y \in Q$ define $y^* = y^{\tau\sigma}$. Suppose that $\bar{x} \leqq x$ and $y \leqq y^*$ for each $x \in P$ and $y \in Q$, respectively. Then it is a standard exercise to verify that $x \to \bar{x}$ is a dual closure operation, $y \to y^*$ is a closure operation, and that σ and τ are inverse isomorphisms (after suitable restriction) between the complete lattices of closed elements of P and Q [1], [2]. The mappings σ, τ are said to establish a *dual Galois correspondence* between P and Q. It is hoped that those with a knowledge of group theory will be able to find interesting applications for the following example of a dual Galois correspondence.

Let G be a group and let $A(G)$ denote its automorphism group, $L(G)$ its lattice of subgroups, and $L(A(G))$ the lattice of subgroups of its automorphism group. Let H be a subgroup of G and let H^σ denote the set of all automorphisms α of G such that $x^{-1}(x)\alpha \in H$ for all $x \in G$.

LEMMA. *H^σ is a subgroup of $A(G)$.*

Proof. Suppose $\alpha, \beta \in H^\sigma$. Then

$$x^{-1}(x)\alpha\beta = x^{-1}(x)\alpha[(x)\alpha]^{-1}[((x)\alpha)\beta] \in H, \qquad x \in G.$$

Thus $\alpha\beta \in H^\sigma$. In a similar way we may show that the inverse of each element of H^σ is in H^σ. Thus H^σ is a group.

Suppose that K is a subgroup of $A(G)$. We define K^τ to be the subgroup generated by the set of all elements of the form $x^{-1}(x)\alpha$, $x \in G$, $\alpha \in K$.

THEOREM 1. *The pair of mappings σ, τ establish a dual Galois correspondence between $L(G)$ and $L(A(G))$.*

Proof. Obvious.

THEOREM 2. *If K is a subgroup of $A(G)$ then K^τ is a normal subgroup of G.*

Proof. It is sufficient to show that $x^{-1}a^{-1}(a)\alpha x$ is in K^τ for each $\alpha \in K$, $a \in G$, and $x \in G$. Now

$$x^{-1}a^{-1}(a)\alpha x = (ax)^{-1}(a)\alpha x = [(ax)^{-1}(ax)\alpha][x^{-1}(x)\alpha]^{-1} \in K^\tau.$$

THEOREM 3. *If K is a normal subgroup of $A(G)$ then K^τ is a characteristic subgroup of G.*

Proof. Let $x^{-1}(x)\alpha$ be a generator of K^τ where $\alpha \in K$, $x \in G$. It is sufficient to show that $(x^{-1}(x)\alpha)\gamma \in K^\tau$ for each $\gamma \in A(G)$. By hypothesis, $\gamma^{-1}\alpha\gamma$ is an element of K, say β. Now

$$(x^{-1}(x)\alpha)\gamma = (x^{-1})\gamma(x)\alpha\gamma = [(x)\gamma]^{-1}(x)\gamma\beta = [(x)\gamma]^{-1}[(x)\gamma]\beta \in K^\tau.$$

THEOREM 4. *If H is a characteristic subgroup of G then H^σ is a normal subgroup of $A(G)$.*

Proof. It is sufficient to show that $x^{-1}(x)\gamma^{-1}\alpha\gamma \in H$ for each $x \in G$, $\alpha \in H^\sigma$, and $\gamma \in A(G)$. Notice that for any $y \in G$ it follows that $(y)\alpha = yh$ for some $h \in H$ since $\alpha \in H^\sigma$. Now

$$x^{-1}(x)\gamma^{-1}\alpha\gamma = x^{-1}[((x)\gamma^{-1})\alpha]\gamma = x^{-1}[(x)\gamma^{-1}h]\gamma = x^{-1}[(x)\gamma^{-1}\gamma][h]\gamma = x^{-1}xh' = h'$$

for some h, $h' \in H$ by the previous sentence and the fact that H is a characteristic subgroup of G. Thus H^σ is a normal subgroup of $A(G)$.

THEOREM 5. *The mapping σ is a complete meet-homomorphism of $L(G)$ into $L(A(G))$ and the mapping τ is a complete join-homomorphism of $L(A(G))$ into the complete sublattice of normal subgroups of $L(G)$.*

Proof. This follows at once from Theorem 2 and well-known properties of closure operations [1], [2].

The work in this paper was done while the author held a National Science Foundation Fellowship at the University of Illinois.

A BEST STATISTIC WITH VARIANCE NOT EQUAL TO THE CRAMÉR-RAO LOWER BOUND

W. C. GUENTHER, University of Wyoming

1. Introduction. The Cramér-Rao inequality is discussed in recent textbooks ([2], [3], and [5]). The inequality provides a nonconstructive method for finding the minimum variance unbiased statistic ("best statistic") for an unknown parameter θ which appears in a probability density function. More recent results, discussed in [2, chap. 8] and [4, chap. 8], provide a constructive procedure for finding a best statistic. For most of the distributions which are frequently studied in a course in mathematical statistics, the variance of the obvious estimate of the parameter satisfies the Cramér-Rao inequality making it unnecessary to call upon the more sophisticated procedures mentioned above. In this paper we present an example in which the best statistic has a variance greater than the Cramér-Rao lower bound and it is quite unlikely that one would uncover the estimate without a constructive approach.

2. The example. Let $X_1, X_2, \cdots, X_n$ be a random sample from a distribution having p.d.f.

$$f(x;\theta) = \theta x^{\theta-1}, \qquad 0 < x < 1, \theta > 0. \tag{1}$$

Let W be an unbiased statistic for θ. Then according to Cramér-Rao

$$\sigma_W^2 \geqq \frac{1}{nE\{[\partial \ln f(X;\theta)/\partial\theta]^2\}}. \tag{2}$$

It is easy to show that

$$\frac{\partial \ln f(X;\theta)}{\partial\theta} = \ln X + \frac{1}{\theta}, \qquad E\left[\left(\ln X + \frac{1}{\theta}\right)^2\right] = \frac{1}{\theta^2},$$

so that $\sigma_W^2 \geqq \theta^2/n$.

The best estimate of θ is easily found. Since (1) is a member of the exponential class of density functions, we immediately know that $Y = -\sum_{i=1}^{n} \ln X_i$ is a sufficient statistic for θ and, according to Theorem 6 ([2] p. 224), the best statistic is a function of Y which has expectation θ. Now

$$E(e^{tY}) = \left(1 - \frac{t}{\theta}\right)^{-n} \qquad t < \theta$$

so that the p.d.f. of Y is $g(y) = (\theta^n/\Gamma(n))y^{n-1}e^{-\theta y}$, $y > 0$. Since $E[(n-1)/Y] = \theta$, we see that $(n-1)/Y = Z$, $n \geqq 2$, is the best statistic. Also it is easy to verify that $\sigma_Z^2 = \theta^2/(n-2) > \theta^2/n$.

3. The improved bound of Bhattacharyya. A special case of a result due to Bhattacharyya [1] for an improved lower bound for the variance of W yields

$$\sigma_W^2 \geqq \frac{\lambda_{22}}{\lambda_{11}\lambda_{22} - \lambda_{12}^2}, \tag{3}$$

where

$$\lambda_{ij} = E[T_iT_j], \qquad T_k = \frac{1}{P}\frac{\partial^k P}{\partial \theta^k}, \qquad P = \prod_{i=1}^{n} f(X_i, \theta).$$

It is easy to show that the Bhattacharyya bound is greater or equal to the Cramér-Rao bound and the two bounds are the same when a statistic exists which produces equality in the latter.

For the density (1) we get

$$\lambda_{11} = E(T_1^2) = E\left[\left(-Y + \frac{n}{\theta}\right)^2\right] = \frac{n}{\theta^2}$$

$$\lambda_{12} = E(T_1T_2) = E\left[\left(-Y + \frac{n}{\theta}\right)^3 - \frac{n}{\theta^2}\left(-Y + \frac{n}{\theta}\right)\right] = -\frac{2n}{\theta^3}$$

$$\lambda_{22} = E(T_2^2) = E\left[\left(-Y + \frac{n}{\theta}\right)^4 - \frac{2n}{\theta^2}\left(-Y + \frac{n}{\theta}\right)^2 + \frac{n^2}{\theta^4}\right] = \frac{2n(n+3)}{\theta^4},$$

where $Y = -\sum_{i=1}^{n} \ln X_i$, $E(Y^k) = [\Gamma(n+k)]/[\theta^k\Gamma(n)]$. Thus (3) yields

$$\sigma_W^2 \geqq \frac{\theta^2}{n}\frac{n+3}{n+1} \quad \text{and we note} \quad \frac{\theta^2}{n} < \frac{\theta^2}{n}\frac{n+3}{n+1} < \frac{\theta^2}{n-2}.$$

A SIMPLE PROOF OF THE SCHRÖDER-BERNSTEIN THEOREM

I. I. KOLODNER, Carnegie Institute of Technology

The objective of the present note is to clarify the proof of the Schröder-Bernstein Theorem given in Suppes ([1], p. 95–96). While in principle our construction does not involve anything beyond what already appears in [1], we stress here the fact that the proof is achieved by finding a fixed point of a certain function. This function turns out to be an isotonic self-mapping of a complete lattice, and thus has a fixed point.

A clarification of this type seems not to have attracted the attention of other expositors. The proof in [1] follows an *ex-machina* pattern: an equation is written, one does this and that, and presto—the conclusion follows. The same attitude is taken by Fraenkel ([2], p. 102–103) on which the proof of [1] is based, and the same is indicated by Dieudonné ([3], p. 10, Exercise 4, and p. 13, Exercise 3) through hints.

The Schröder-Bernstein Theorem asserts: *If the functions* f_1: $X_1 \to X_2$ *and* f_2: $X_2 \to X_1$ *are one-to-one, then there exists a function* g: $X_1 \to X_2$ *which is one-to-one and onto.*

The beginning of our proof is standard: the assertion follows if one can produce subsets $A_1 \subset X_1$ and $A_2 \subset X_2$ such that

$$f_1(A_1) = A_2' \quad \text{and} \quad f_2(A_2) = A_1'. \tag{1}$$

(Primes denote complements.) Indeed, the restrictions $f_1|A_1$: $A_1 \to A_2'$ and $f_2|A_2$: $A_2 \to A_1'$ are then one-to-one and onto functions and thus g: $X_1 \to X_2$ defined by

$$g(x) = \begin{cases} f_1(x), & \text{if } x \in A_1, \\ (f_2|A_2)^{-1}(x), & \text{if } x \in A_1', \end{cases} \tag{2}$$

has the desired property.

The functions f_1 and f_2 induce associated set functions F_1: $P(X_1) \to P(X_2)$ and F_2: $P(X_2) \to P(X_1)$ on the corresponding power sets, where $F_i(U) = \{f_i(x) \mid x \in U \in P(X_i)\}$, $i = 1, 2$. Let C_i: $P(X_i) \to P(X_i)$, $i = 1, 2$ be the complement function, i.e., $C_i(U) = U' \subset X_i$. Then condition (1) implies that the pair (A_1, A_2) will be a suitable pair of sets if and only if it is a solution of the pair of conditional equations

$$F_1(x) = C_2(y), \qquad F_2(y) = C_1(x). \tag{3}$$

Thus it suffices to show that (3) has a solution.

Eliminating y from equations (3) we now get a *single fixed point equation* for $P(X_1)$,

$$x = K(x), \quad \text{where} \quad K = C_1 \circ F_2 \circ C_2 \circ F_1 : P(X_1) \to P(X_1). \tag{4}$$

It is easily checked that if U is a solution of (4) then the pair $(U, (C_2 \circ F_1)(U))$

is a solution pair of the system (3). Thus our objective is now to show that K has a fixed point.

To solve (4) observe that F_1 and F_2, being set functions induced by point functions, are isotonic (i.e., order preserving) under the orderings of $P(X_1)$ and $P(X_2)$ by set inclusion. The complements C_1 and C_2 are antitonic (i.e., order inverting) functions. Thus K, being a composition of two isotonic and two antitonic functions, is an isotonic function.

At this point we may invoke a well known fixed point theorem for isotonic functions since $(P(X_1), \subset)$ is a complete lattice; see, e.g., [4], p. 54. The matter is so simple, however, that we hardly need a reference to finish the proof. Let

$$S = \{x \in P(X_1) \mid x \subset K(x)\};$$

S is not empty, since $\varnothing \subset K(\varnothing)$. We shall show that $U = \bigcup\{x \in S\}$ is a fixed point of K. If $a \in U$, then $a \in x$ for some $x \in S$ and so $a \in K(x)$; since K is isotonic and $x \subset U$, it follows that $K(x) \subset K(U)$ whence $a \in K(U)$, or $U \subset K(U)$. Since K is isotonic, this yields $K(U) \subset K(K(U))$ showing that $K(U) \in S$. From the definition of U we now conclude that $K(U) \subset U$, and consequently $U = K(U)$, as asserted.

Coming back to the original question, we see that $A_1 = U$, $A_2 = (C_2 \circ F_1)(U)$ is a pair satisfying the conditions (1).

ON NEWTON-RAPHSON ITERATION

J. F. TRAUB, Bell Telephone Laboratories, Murray Hill, N. J.

Let α be a zero of multiplicity m, $m \geqq 1$, of a sufficiently smooth function f and assume that f' does not vanish in the interval of interest except possibly at α. For the case of a simple zero, the Newton-Raphson iteration function ϕ is usually derived by linearizing f using the first two terms of its Taylor series about an arbitrary point. The error term is obtained from the remainder of the Taylor expansion of f or from the expansion of ϕ around α, [1, pp. 20, 75]. The error term involves an unknown parameter. The case of multiple zeros is usually handled [1, Chapter 7] separately from that of simple roots.

We give a method for deriving formulas for the iteration function and its error simultaneously. Simple and nonsimple zeros are handled together.

We then give a novel principle for the construction of iteration functions and apply it to the derivation of the Newton-Raphson and Halley iteration functions.

Let

$$f(t) = (t - \alpha)^m Q(t). \tag{1}$$

Then

$$f'(t) = m(t - \alpha)^{m-1}Q(t) + (t - \alpha)^m Q'(t) \tag{2}$$

and $(t-\alpha)f'(t) = mf(t) + (t-\alpha)^{m+1}Q'(t)$. Hence

$$\alpha = t - m\frac{f(t)}{f'(t)} - (t - \alpha)^{m+1}\frac{Q'(t)}{f'(t)}. \tag{3}$$

Let $\phi(t) = t - m[f(t)/f'(t)]$. Then

$$\phi(t) = \alpha + (t - \alpha)^{m+1}\frac{Q'(t)}{f'(t)}. \tag{4}$$

$\phi(t)$ is the Newton-Raphson iteration function for a zero of multiplicity m and (4) is an expression for the error.

From (2) and (4),

$$\frac{\phi(t) - \alpha}{(t - \alpha)^2} = \frac{Q'(t)}{mQ(t) + (t - \alpha)Q'(t)}. \tag{5}$$

Hence

$$\lim_{t\to\alpha}\frac{\phi - \alpha}{(t - \alpha)^2} = \frac{Q'(\alpha)}{mQ(\alpha)}. \tag{6}$$

By expanding $Q(t)$, $Q(t) = [f^{(m)}(\alpha)/m!] + [f^{(m+1)}(\alpha)/(m+1)!](t-\alpha) + \cdots$, we obtain

$$\lim_{t\to\alpha}\frac{\phi - \alpha}{(t - \alpha)^2} = \frac{f^{(m+1)}(\alpha)}{m(m + 1)f^{(m)}(\alpha)}, \tag{7}$$

which is a standard result.

If α is a simple zero,

$$\begin{aligned} \phi &= \alpha + (t - \alpha)^2[Q'(t)/f'(t)], \\ \phi &= \alpha + (t - \alpha)^2\frac{f''(t)}{2f'(t)} - (t - \alpha)^3\frac{Q''(t)}{2f'(t)}. \end{aligned} \tag{8}$$

From (7) or (8) we obtain the usual relation for the case of simple roots,

$$\frac{\phi - \alpha}{(t - \alpha)^2} \to \frac{1}{2}\frac{f''(\alpha)}{f'(\alpha)}.$$

We now obtain the Newton-Raphson iteration function from another point of view. Assume that α is a simple zero. From (1),

$$\alpha = t - (f/Q). \tag{9}$$

Q is not known but we approximate it as well as possible from available information. From $Q(t) = f'(t) - (t-\alpha)Q'(t)$ we observe that f' differs from Q by terms of order $t-\alpha$ and hence we approximate Q by f' in (9) to obtain the Newton-Raphson iteration function.

One may show that

$$Q = T + \frac{(t-\alpha)^2}{2}\left[Q'' - f''\frac{Q'}{f'}\right], \qquad T = f' - \frac{f''}{2}\frac{f}{f'}.$$

That is, T differs from Q by terms of order $(t-\alpha)^2$. This suggests the iteration function

$$\phi = t - \frac{f}{T} = t - \frac{f}{f' - (f''f/2f')}.$$

But this is just Halley's third-order iteration. A brief historical survey of this often rediscovered iteration function may be found in [1, p. 91].

A SIMPLE PROOF OF THE CHINESE REMAINDER THEOREM

C. J. Mozzochi, University of Connecticut

Chinese Remainder Theorem. *Let $m_1, \cdots, m_n$ be relatively prime integers. Let $a_1, \cdots, a_n$ be arbitrary integers. Then*:

1. *The congruences $x \equiv a_i \pmod{m_i}$ $i = 1, \cdots, n$ have at least one simultaneous solution.*

2. *Any two simultaneous solutions are congruent modulo $m_1 \cdots m_n$.*

The proof follows directly from the following result of number theory:

A. Suppose that $m_1, \cdots, m_n$ are pairwise relatively prime integers. Then $x \equiv y \pmod{m_i}$ $i = 1, \cdots, n$ if and only if $x \equiv y \pmod{m_1 \cdots m_n}$.

Proof. If $a \in Z$, let $[x]_a = \{y \mid x \equiv y \bmod a\}$ and let Z_a be the set of all residue classes modulo a. Define

$$\alpha: Z_{m_1 \cdots m_n} \to Z_{m_1} \times \cdots \times Z_{m_n} \text{ by } ([x]_{m_1 \cdots m_n})\alpha = ([x]_{m_1}, \cdots, [x]_{m_n})$$

for each $x \in Z$. By A, α is a well-defined, 1-1 mapping of $Z_{m_1 \cdots m_n}$ into $Z_{m_1} \times \cdots \times Z_{m_n}$. Since $\text{Card}(Z_{m_1 \cdots m_n}) = m_1 \cdots m_n = \text{Card}(Z_{m_1} \times \cdots \times Z_{m_n})$, α is onto. But then, given integers $a_1, \cdots, a_n$ there is an integer x such that $([x]_{m_1 \cdots m_n})\alpha = ([a_1]_{m_1}, \cdots, [a_n]_{m_n})$ and therefore $x \equiv a_i \bmod m_i$, $i = 1, \cdots, n$. By A, any two solutions are congruent modulo $m_1, \cdots m_n$.

MATHEMATICAL EDUCATION NOTES

EDITED BY JOHN R. MAYOR, AAAS
COLLABORATING EDITOR: JOHN A. BROWN, University of Delaware

All material for this department should be sent to John R. Mayor, 1515 Massachusetts Avenue, N.W., Washington D.C. 20005

WHAT ADVANCED DEGREE WITHOUT MATHEMATICS RESEARCH?

G. R. RISING, State University of New York at Buffalo

You probably all know the story of the African explorer who lived among the lions so long that he came to know their language. (I say probably because I first read it in this journal in a delightful article by Moses Richardson.) Much to his surprise he found that the lions believed God was a lion. Compare this story with my own experience among the mathematicians. When I told how we wanted to build a doctoral program in mathematics education which would have significance for our many students who staff or will staff mathematics departments in state colleges, I was taken aback by the rejoinder that since those people are to teach mathematics, they should be in mathematics and *not* education programs.

For a great many reasons I disagree with this attitude. The staff in mathematics education does not wish to infringe upon the central role of the mathematics department producing research mathematicians—but rather to play a cooperative (and service) role in training teachers of undergraduate mathematics. It is evident that there are not now enough research-oriented mathematicians to staff undergraduate mathematics programs. I wish to defend the stand: *The degree appropriate to college mathematics teachers who do not choose to become mathematical researchers is in many cases the doctorate in mathematics education.*

The program we are establishing will require:

(1) The equivalent of more than a master's degree (30 hours) in graduate mathematics. (Those students who do not have undergraduate mathematics majors must fulfill upper division undergraduate requirements in addition to this.)

(2) A major field examination made out in cooperation with mathematics department members.

(3) A thesis (usually empirical, possibly historical or philosophical) with at least one mathematician on the committee.

(4) A strong dose of psychology and research design when the study is empirical.

(5) Course work in mathematics education involving curricular and pedagogical problems.

(6) A minimum amount (usually 8 semester hours) of additional education course work.

This program is clearly interdisciplinary. The guidance of an individual student will be undertaken in close cooperation with the departments both of mathematics and of psychology (or history or philosophy).

Here is an example of the course work a student planning an empirical dissertation might elect.

This program gives the student a good background in mathematics taught by members of the mathematics department designed to give breadth of understanding of the field as well as an educational background useful in teaching courses in mathematical pedagogy and in working with teachers in elementary and secondary schools.

It also develops his ability to produce scholarly research, not in mathematics, to be sure, but in mathematical pedagogy, in which he can and usually will carry out further studies, whereas for the Ph.D. mathematician in the same school the last piece of research is often his first. The student has adequate guidance in this program. In the mathematics department he would be low man, working on a non-research project to which his advisor, by the very nature of his work, is not deeply committed.

This program solves the problem of providing an alternate route for students who wish to teach undergraduate mathematics in reputable but not research-oriented institutions.

Instead of creating a new second-rate degree, instead of faking a dissertation, instead of turning away talented but non-research-oriented students, I suggest once again that a degree now offered be utilized and strengthened by cooperation between mathematicians and mathematics educators. In competition the mathematicians, the educators, and the students would, it seems to me, all be losers.

ALTERNATIVES TO RESEARCH

D. E. CHRISTIE, Bowdoin College and J. H. WELLS, University of Kentucky and Institute for Advanced Study

A formidable challenge to excellence is posed by two trends in collegiate mathematics education: one is the admirable flow of numerous students into fields requiring mathematics, with a consequent demand for good college teachers; the other is the lamentable tendency for undergraduate mathematics faculties to be understaffed and overworked. The two trends together generate a challenge which the CUPM Panel on College Teacher Preparation now confronts: How can undergraduate faculty members achieve and maintain high quality in mathematics teaching?

Let us assume that active enthusiasm for mathematics is one prerequisite for excellent teaching. At universities, we expect research-oriented professors to impart a sense of mathematics as a growing, beautiful subject. Mathematics students at colleges need similar insight and inspiration. In this article we consider questions which represent one facet of the challenge just cited: Can a college teacher be a truly professional mathematician without doing research? What can take the place of research in keeping mathematics teachers alive? Our intention in suggesting answers to these questions is twofold. We hope that individual teachers will find things which they may wish to do. We also hope that strong departments and officers of societies will recognize ways in which they can and should assist their neighbors and constituents.

First, there are some standard mental push-ups by which an isolated and busy teacher can strive to remain current. These activities are closely associated with courses which he gives. He may:

1. Read, in a modern treatise more advanced than the textbook he uses, chapters parallel to class assignments.
2. Scan books and articles in a search for lively examples and applications.
3. Prepare a syllabus for outside independent reading for his better students.
4. Write substitute units because of his dissatisfaction with a textbook.
5. Do minor research, puzzling over questions arising naturally in his courses.

In summary, courses taught are a first natural avenue to creative activity.

Secondly, the college teacher may take more drastic positive measures to keep his teaching fresh. He may:

6. Join with others in an interdepartmental course, seminar, or project.
7. Conduct one of his courses experimentally in developmental or seminar style, realizing that no longer will it be enough to give routine and perfunctory attention to the course.
8. Seek out a summer conference or a neighborhood coalition in which improvements for a crucial course can be worked out.
9. Find motivation for effort or change by acquiring from graduate departments precise descriptions of key first year graduate courses along with preferred or minimal undergraduate requirements. (This information, rarely found in catalogues or brochures, will be of value to his students as well as to him.)

Third, he may try to take better advantage of a fleeting but invaluable asset, the presence of students who have exceptional aptitude and energy. He may:

10. Advise interested students concerning competitive opportunities: e.g., the Putnam contest, problems in *Monthly*, *Magazine*, etc.
11. Organize a mathematics club, or meeting of majors, at which talks are given by advanced students as well as staff and visitors.
12. Urge one or more of his best students to undertake independent reading with weekly lectures to him.
13. Establish, in connection with a course at any level, a project seminar at which reports are given by students.

Fourth, if he has opportunity and incentive, he may make a major investment of time in professional activity. He may:

14. Read expository articles and books (e.g., MAA publications) particularly if it is made easy for him to find them.
15. Read review articles on recent advances in mathematics.
16. Attend a summer institute (there should be many more summer programs for college teachers).
17. Participate in a study group with occasional area conferences and exchange by mail of working papers. (The assumption here is that someone has diagnosed and called attention to a particular need.)
18. Spend his sabbatical at a university where he is really welcome and will receive advice about a program valid for him.

Additional or modified measures can easily be added to this list.

Several of the alternatives to research listed above come close to research without having new theorems as a main objective. Lifting a sentence from a recent letter to *Science* by George W. Mackey (discussing a rather different issue): "Reworking old material fades imperceptibly into discovery of new, and what starts with an attempt to understand something old from a personal point

of view often results in new progress and new discoveries," [1]. The good college teacher of mathematics, who does not consider himself a research mathematician, will often teach creatively if there is time, motivation, opportunity, and perhaps some guidance.

There is no substitute for *time*. A teacher burdened with a fifteen hour teaching load and a normal budget of committee work will find it difficult to respond to challenges such as we have outlined. Note then the need for compensating released time for the creative teacher as well as for the research man.

If time is available, what are the sources of *motivation?* Teachers tend to respond to opportunities closely related to their own courses and their own students. New programs to assist teachers should then emphasize relevance to teaching objectives. Active support by department chairmen and encouragement of colleagues are essential. Productive mathematical activity should earn both appreciation and tangible reward. Teachers and administrators should learn to recognize the distinction between routine performance of academic chores and a genuinely professional involvement in mathematics. The teacher must be convinced that beneficial mathematical activity on his part is needed and expected, and that his rewards will exceed those of less dedicated colleagues.

Finally, can the well motivated teacher of undergraduates, with time available, actually find the *means* and *opportunity* of pursuing the goals we have so freely listed? Certainly there is already an impressive reservoir of good books for parallel study by a teacher or independent reading by a good student. Many of these are listed in the *Basic Library List* of CUPM. For example, a modest but extremely worthwhile project would be to study and work problems in Courant or Apostol while teaching a course in calculus, or to study Halmos' book *Finite Dimensional Vector Spaces* while teaching a sophomore course in linear algebra. In the direction of independent work for better students, an excellent project for juniors and seniors is the preparation of a problem notebook based on Boas' book *Primer of Real Functions*. Expository articles always seem scarce, but excellent ones can be found in MAA and NCTM publications and in other sources mentioned in the *List*. There is reason to expect that mathematical publications will in the future more closely assist the needs of the professional college teacher who is not committed to research. It is well known that research-oriented professors of mathematics are a minority group just as research-minded physicians are a minority group in the medical profession. The needs of the mathematical minority are magnificently provided for by the American Mathematical Society. The interests of the majority are increasingly heeded in other organizations.

Obviously not all of the activities listed above exist for each individual teacher, and even if they do he may not know of them. College mathematics teachers are greatly in need of a means of communication which would keep all of them fully abreast of professional opportunities (e.g., 8, 16, 17, 18). Because of the existing lack of communication, many college teachers are unaware of the availability of Federal support for activities other than pure research. Both the National Science Foundation and the Department of Health, Education, and

Welfare support curriculum reform and innovation, staff training, and experimental research. We urge each college mathematics department, especially those who have not done so in the past, to become informed about these services. Direct inquiries will bring information about conferences, institutes, and other opportunities for college teachers. Furthermore, CUPM serves as a clearing house for information concerning curricular developments. The CUPM Consultants Bureau and the MAA Visiting Lecturer Program bring timely professional counsel to campuses making a request.

Mathematicians, either in or out of research, keep alive through the creative interaction of minds. Such interaction is possible even to the isolated busy teacher through books, journals, conferences, seminars, and institutes, as well as through contacts with students and colleagues. Never before have college teachers of mathematics been offered so much assistance aimed at restoring their vitality and at promoting their productivity. But never before has the responsibility for vigorous initiative lain on so many shoulders. Each teacher, as always, must seek for himself an optimal but realistic program of continuing study and exploration. Each department chairman bears a special responsibility to encourage junior members to stay alive professionally, to see that the bright young men have assignments which will challenge them, and to adjust teaching loads so that the professionally oriented teacher has free time for his work. College administrations bear similar responsibilities. Increasingly, the research departments must design and initiate programs for the strengthening of their neighbors (from whom they receive graduate students). Conferences, exchanges of staff, and sabbatical hospitality require initiative from the strong departments. The officers and leaders of professional organizations need now, more than in the past, to analyze and to fulfill the needs of the majority of their profession rather than merely to communicate with each other.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, University of Massachusetts; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions of Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before February 29, 1968. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.

E 2015. *Proposed by W. A. McWorter, University of British Columbia*

Let $\ll$ be an anti-reflexive partial order on the set $\{1, \cdots, n\}$. Let A be an $n \times n$ matrix where the (i, j)-entry is 1 or 0 according as $i \ll j$ or not. (i) Prove that there exists a permutation matrix P such that PAP^{-1} is upper triangular. (ii) Show that $A = 0$ if A is idempotent (i.e., $A^2 = A$).

E 2016. *Proposed by J. M. Khatri, Baroda, India*

Let Δ_r be the triangular number $\frac{1}{2}r(r+1)$. Solve in integers the system:

$$\Delta_a + \Delta_b = \Delta_c + \Delta_d, \qquad x^2 + y^2 = z^2 + w^2,$$
$$\Delta_{a+x} + \Delta_{b+y} = \Delta_{c+z} + \Delta_{d+w}.$$

E 2017. *Proposed by Stanley Rabinowitz, Far Rockaway, N. Y.*

Let h be the length of an altitude of an isosceles tetrahedron and suppose the orthocenter of a face divides an altitude of that face into segments of lengths h_1 and h_2. Prove that $h^2 = 4h_1h_2$.

E 2018. *Proposed by W. A. McWorter, University of British Columbia*

Let M_n be the group of all nonsingular $n \times n$ matrices over a field F of characteristic 0. Let S_n be the subgroup of M_n consisting of all permutation matrices. Prove that if two elements of S_n are conjugate in M_n, then they are already conjugate in S_n.

E 2019. *Proposed by Norman Miller, Queen's University, Kingston, Ontario*

Given four noncollinear, nonconcyclic points in a plane, show that (a) at

most three of the points can each be outside the circle that passes through the other three, and (b) at most two of the points can each be inside the circle that passes through the other three.

E 2020. *Proposed by G. F. Schumm, University of Chicago*

Given n points ($n>3$) such that no three are collinear and no four concyclic. Must there exist a circle which passes through three of them and contains the remaining points in its interior?

E 2021. *Proposed by D. S. Mitrinović, University of Belgrade*

If $|\bar{a}b-\bar{b}c| = |a\bar{a}-c\bar{c}|$, determine whether the equation $az^2+bz+c=0$ (a, b, c complex numbers, $a\neq 0$, $|a| \neq |c|$) has a root z_1 with the property $|z_1| = 1$. The converse is known. (See the proposer's book, *Functions of a Complex Variable*, Nordhoff, 1965, p. 38, #2.13.)

E 2022. *Proposed by Richard Parris, Student, Tufts University*

Ordered k-tuples are formed using the two symbols A, B. In how many ways can this be done, if it is required that "A" does not occur in adjacent positions? I.e., for $k=3$, the triples (A, A, A), (A, A, B), (B, A, A) are not counted.

E 2023. *Proposed by L. F. Meyers, The Ohio State University*

Which fields have nonzero elements a and b such that $a^2+b^2=1$? Generalize.

E 2024. *Proposed by R. B. Eggleton, Avondale College, Cooranbong, Australia*

In discussing the number $F_{73}=2^{2^{73}}+1$, W. W. Rouse Ball states: "Its digits are so numerous that, if it were printed in full with the type and number of pages used in this book, many more volumes would be required than are contained in all the public libraries in the world." (*Mathematical Recreations and Essays*, Eleventh (revised) edition, 1963.) (a) Is this an exaggeration? (b) What are the last three digits of F_{73}?

SOLUTIONS OF ELEMENTARY PROBLEMS

Additive, weakly multiplicative functions

E 1895 [1966, 664]. *Proposed by A. A. Gioia, Texas Technological College*

Let a complex-valued arithmetic function f be called

(1) additive if $f(a+b)=f(a)+f(b)$,

(2) weakly multiplicative if $f(ab)=f(a)f(b)$, whenever $(a, b)=1$,

(3) strongly multiplicative if $f(ab)=f(a)f(b)$.

Prove that if a function is additive and weakly multiplicative, then it is strongly multiplicative.

Solution by Z. Z. Uoiea, Salt Lake City, Utah. Condition (1) and induction imply that $f(n)=nf(1)$. By (2), $f(1)=f(1)^2$, so that $f(1)=0$ or 1. Hence $f(n)\equiv 0$ or $f(n)\equiv n$. In both cases, f satisfies (3).

Also solved by Harold Abelson, D. T. Adams, R. G. Archibald, Anders Bager (Denmark), T. L. Bartlow, Brother Louis Zirkel, J. L. Brown, Jr., Peter Bundschuh (Germany), T. J. Burke, J. P. Celenza, G. C. C. Chang, Mannis Charosh, P. R. Chernoff, John Christopher, R. J. Cormier, Red Cougar, J. H. Cozzens & M. S. Kaplan, Eleanor G. Dawley, D. E. Daykin (Malaysia), Bob De Vore, Stan Dick & Preston Stein, J. F. Dillon, W. G. Dotson, Jr., D. R. Duncan, E. S. Eby, H. M. W. Edgar, R. B. Eggleton (Australia), M. A. Fechter, Neal Felsinger, M. S. Fineman, Annabel Fong, E. A. Franz, F. N. Fritsch, Philip Fung, N. Ganesan (India), Richard Gisselquist, R. E. Giudici, Anton Glaser, Michael Goldberg, Frederic Gooding, Jr., M. G. Greening (Australia), G. A. Heuer, K. E. Hirst (England), J. E. Homer, Jr., J. A. Hornby & P. M. Ellis, D. G. Huffman, R. A. Jacobson, Erwin Just, Michael Kerwan; Stephen Kiely & Anthony La Bruzza, Fred Kochman, Betty Kvarda, R. N. Leggett, Jr., Joel Levy, Charles McCracken, Norman Miller, J. A. Mokoena (Zambia), H. V. Monks, Alexander Morgan, J. B. Muskat, D. E. Myers, Dave Nixon, Michael Olinick, Robert Prener, Bob Prielipp, J. R. Purdy, Stanley Rabinowitz, B. L. S. P. Rao (India), Jürg Rätz (Switzerland), C. Riley, D. C. Rine, R. N. Schneider, Michael Schulz, G. F. Schumm, Margaret B. Seay, N. E. Sexauer, David Sibley, D. L. Silverman, Stephen Soldz, Al Somayajulu, Stephen Spindler, Sidney Spital, S. T. Stern, Walter Stromquist, P. K. Subramanian, Kishore Theckedath (India), A. M. Vaidya (India), C. S. Venkataraman & R. Sivaramakrishnan (India), J. E. Vinson, A. D. Wadhwa (India), Charles Wexler, Mary M. Whiteside, J. E. Wilkins, Jr., Dale Woods, K. L. Yocom, G. J. Zaher, Jr., Joel Zinn, and the proposer.

Red Cougar, F. N. Fritsch and Alexander Morgan each show that also $f(n)=0$ or n if (2) is replaced by the weaker hypothesis:

(2′) extremely weakly multiplicative if $f(ab)=f(a)f(b)$ for some pair of nonzero integers a, b.

A Congruence

E 1896 [1966, 665]. *Proposed by David Singmaster, University of California, Berkeley*

For every prime p show that

$$\binom{np}{p} \equiv n \pmod{p^2}.$$

I. *Solution by P. R. Chernoff, Harvard University.* From the identity $(1+x)^{np} = ((1+x)^p)^n$ we obtain

$$\binom{np}{p} = \sum_{k_1+\cdots+k_n=p} \binom{p}{k_1} \cdots \binom{p}{k_n}.$$

Since $\binom{p}{k}$ is divisible by p for $0<k<p$, every term in the above sum is divisible by p^2 except the n terms, each equal to 1, in which one of the k_i is equal to p. Thus $\binom{np}{p} \equiv n \pmod{p^2}$.

II. *Solution by M. A. Fechter, Orlando, Fla.* For $p>3$, Guérin (L'intermédiare des math., 23 (1916) 174) gives, in effect, the much stronger result

$$\binom{kp^m - 1}{p-1} \equiv 1 \pmod{p^{m+2}}, \qquad p \nmid k.$$

Setting $n=p^rk(r\geqq 0)$, we get

$$\frac{1}{n}\binom{np}{p}=\binom{np-1}{p-1}=\binom{kp^{r+1}-1}{p-1}\equiv 1 \pmod{p^{r+3}}.$$

Thus $\binom{np}{p}\equiv n \pmod{p^{2r+3}}$ where $p>3$, $p^r \mid n$, $p^{r+1}\nmid n$. For $p>3$ this is a stronger result than required. The cases $p=2$ and $p=3$ can easily be taken care of.

Also solved by Anders Bager (Denmark), Sister Marion Beiter, W. J. Blundon, Robert Breusch, P. Bundschuh (Germany), Mannis Charosh, Anton Chernoff, Raymond Chu, J. H. Cozzens, J. F. Dillon, R. E. Eggleton (Australia), Mrs. A. Elek (Hungary), Udovičić Enes (Yugoslavia), Marco Ettrick, M. A. Fechter, Michael Goldberg, Jerry Goodman, A. L. Gould, M. G. Greening (Australia), Jerome Harrison, Scott Harrod, W. E. Hoff, F. T. Howard, Donald Jeffords, M. S. Kaplan & J. H. Cozzens, H. E. Lahmann (Germany), Douglas Lind, W. W. Meyer, Norman Miller, H. V. Monks, Wanda Jane Mourant, J. B. Muskat, Slamar Ninoslav (Yugoslavia), Stanton Philipp, J. R. Purdy, Stanley Rabinowitz, Jürg Rätz (Switzerland), Lois J. Reid, Marilyn Rodeen, Harry Ruderman, Robert Spira, E. W. Trost (Switzerland), J. E. Vinson, A. D. Wadhwa (India), Charles Wexler, and the proposer.

Editorial Note. Charosh also establishes $\binom{np}{p}\equiv n \pmod{p^3}$ for $p>3$.

In the solution of E 1346 [1959, 591] which was to show that $\binom{2p}{2}\equiv 2 \pmod{p}$, N. G. Gunderson established that for $p>3$, $a>0$, we have

$$\binom{ap^n}{p}\equiv ap^{n-1} \pmod{p^{2n+1}}.$$

Now let $n=1$.

Expected Distance between Vertices of a Dodecahedron

E 1897 [1966, 665]. *Proposed by F. P. Callahan, Blue Bell, Pa.*

A bug is crawling on the edges of a regular dodecahedron. Each time it comes to a vertex it chooses with equal probability one of the two edges which end in that vertex distinct from the one by which it reached that vertex. What is the expected distance it covers in order to get from a vertex A to any other vertex B? ($A=B$ is not excluded.) On starting, the bug can go in any of the three directions. (Cf. E 1752 [1966, 200].)

Solution by J. R. Kuttler and Nathan Rubinstein, The Johns Hopkins University Applied Physics Laboratory. Let the dodecahedron have unit edges and let B denote the point at which the bug terminates his journey. Let the remaining points be labeled A_1, A_2, A_3, A_4 or A_5 as the minimum number of edges the bug traverses to reach B is 1, 2, 3, 4 or 5, respectively. (See Fig. 1.)

Let $E(A_i, A_j)$ denote the expected distance the bug will travel to reach B if he is at vertex A_i and chooses the edge from A_i terminating at A_j. From Fig. 1 we immediately obtain the linear system:

$$\begin{aligned}
E(A_1, B) &= 1, \qquad E(B, A_1) = 1 + E(A_1, A_2),\\
E(A_1, A_2) &= 1 + \tfrac{1}{2}E(A_2, A_2) + \tfrac{1}{2}E(A_2, A_3),\\
E(A_2, A_1) &= 1 + \tfrac{1}{2}E(A_1, A_2) + \tfrac{1}{2}E(A_1, B),\\
E(A_2, A_2) &= 1 + \tfrac{1}{2}E(A_2, A_1) + \tfrac{1}{2}E(A_2, A_3),
\end{aligned}$$

$$E(A_2, A_3) = 1 + \tfrac{1}{2}E(A_3, A_3) + \tfrac{1}{2}E(A_3, A_4),$$
$$E(A_3, A_2) = 1 + \tfrac{1}{2}E(A_2, A_1) + \tfrac{1}{2}E(A_2, A_2),$$
$$E(A_3, A_3) = 1 + \tfrac{1}{2}E(A_3, A_2) + \tfrac{1}{2}E(A_3, A_4),$$
$$E(A_3, A_4) = 1 + \tfrac{1}{2}E(A_4, A_3) + \tfrac{1}{2}E(A_4, A_5),$$
$$E(A_4, A_3) = 1 + \tfrac{1}{2}E(A_3, A_2) + \tfrac{1}{2}E(A_3, A_3),$$
$$E(A_4, A_5) = 1 + E(A_5, A_4), \qquad E(A_5, A_4) = 1 + E(A_4, A_3).$$

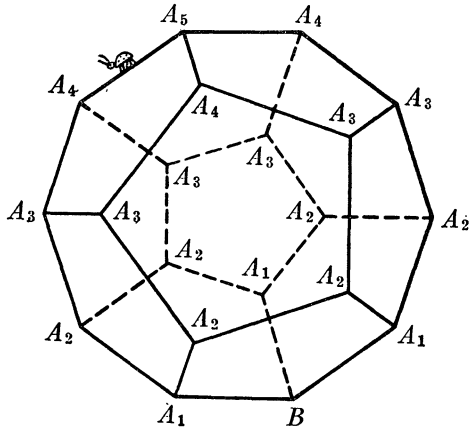

FIG. 1. Bug on dodecahedron.

Solving this system gives:

$$E(A_1, B) = 1, \quad E(B, A_1) = 20, \quad E(A_1, A_2) = 19,$$
$$E(A_2, A_1) = 11, \quad E(A_2, A_2) = \tfrac{49}{3}, \quad E(A_2, A_3) = \tfrac{59}{3},$$
$$E(A_3, A_2) = \tfrac{44}{3}, \quad E(A_3, A_3) = 18, \quad E(A_3, A_4) = \tfrac{58}{3},$$
$$E(A_4, A_3) = \tfrac{52}{3}, \quad E(A_4, A_5) = \tfrac{58}{3}, \quad E(A_5, A_4) = \tfrac{55}{3}.$$

Now it is clear that the desired expected path lengths $E(A_i)$ for the bug starting at A_i and traveling in any direction are given by

$$E(A_5) = E(A_5, A_4) = \tfrac{55}{3},$$
$$E(A_4) = \tfrac{1}{3}E(A_4, A_5) + \tfrac{2}{3}E(A_4, A_3) = 18,$$
$$E(A_3) = \tfrac{1}{3}E(A_3, A_4) + \tfrac{1}{3}E(A_3, A_3) + \tfrac{1}{3}E(A_3, A_2) = \tfrac{52}{3},$$
$$E(A_2) = \tfrac{1}{3}E(A_2, A_3) + \tfrac{1}{3}E(A_2, A_2) + \tfrac{1}{3}E(A_2, A_1) = \tfrac{47}{3},$$
$$E(A_1) = \tfrac{2}{3}E(A_1, A_2) + \tfrac{1}{3}E(A_1, B) = 13,$$
$$E(B) = E(B, A_1) = 20.$$

It is interesting to note that the longest expected path length occurs when the bug starts at the same point on which he terminates.

Also solved by Jorge Dou (Spain), and by the proposer.

A Primitive Root of Unity Identity

E 1899 [1966, 665]. *Proposed by C. R. Knapp, University of Kansas*

If a_k denotes any primitive nth root of unity, prove that

$$a_k^{k\phi(n)-1} = e^{2\pi i/n} = a_1,$$

where $\phi(n)$ is the Euler totient function.

Solution by Donna J. Seaman, Olympic College, Bremerton, Wash. By the Euler-Fermat theorem, $k^{\phi(n)} \equiv 1 \pmod{n}$ where $(k, n) = 1$. Since a_k is a primitive nth root if $(k, n) = 1$, we have at once

$$a_k^{k\phi(n)-1} = e^{2\pi i/n} = a_1.$$

Also solved by Harold Abelson, Anders Bager (Denmark), Red Cougar, J. F. Dillon, M. A. Fechter, R. E. Giudici, Michael Goldberg, Donald Jeffords, Wanda Jane Mourant, J. B. Muskat, C. B. A. Peck, J. R. Purdy, Stephen Soldz, Charles Wexler, and the proposer.

Simultaneous Diophantine Equations

E 1900 [1966, 665]. *Proposed by D. R. Rao, Secunderabad, India*

Find the solution of the system $X+Y=Z+U=W^2$, $X^2+Y^2=Z^2-U^2$, where X, Y, Z, U, W are positive integers.

Solution by N. J. Fine, the Pennsylvania State University. Let us assume, as we may, that we have a solution with $X \geqq Y$. Then

$$\frac{X^2 + Y^2}{X + Y} = \frac{Z^2 - U^2}{Z + U} = Z - U,$$

so $X+Y$ divides X^2+Y^2. Hence, $X+Y$ divides

$$2(X^2 + Y^2) - (X + Y)^2 = (X - Y)^2.$$

We may therefore write $(X-Y)^2 = t(X+Y) = tW^2$, so $t = s^2$, $s \geqq 0$. Since $X \geqq Y$, $X-Y = sW$. Because $X-Y < X+Y = W^2$, we have $s < W$. Next,

$$X^2 + Y^2 = \tfrac{1}{2}[(X + Y)^2 + (X - Y)^2] = \tfrac{1}{2}W^2(W^2 + s^2),$$

so $Z-U = (X^2+Y^2)/(X+Y) = \frac{1}{2}(W^2+s^2)$. Therefore $s \equiv W \pmod{2}$, so we may write $W = s+2v$, with $0 < v \leqq W/2$. Solving, we get

$$\begin{aligned} X &= W^2 - vW, & Y &= vW, \\ Z &= W^2 - vW + v^2, & U &= vW - v^2. \end{aligned} \tag{1}$$

Conversely, for every pair of integers v, W with $0<v\leqq W/2$, equations (1) yield a solution of the original system with $X\geqq Y$. It is easy to see that $(X, Y, Z, U)=(v, W)^2$. Thus the primitive solutions correspond to $(v, W)=1$.

Also solved by Robert Bart, W. J. Blundon, P. R. Chernoff, M. E. Christie, W. C. Daugherity, Buster Dunsmore, R. E. Edwards, R. B. Eggleton (Australia), M. A. Fechter, Michael Goodman, M. G. On the Product of the Areas of Three Triangles

E 1901 [1966, 665]. *Proposed by Richard Laatsch, Miami University, Oxford, Ohio*

Let $\triangle ABC$ have unit area. Construct $\triangle A'B'C'$ such that each of A, B, C is an interior point on a different one of its sides. (Label so that A and A' are on opposite sides of BC, etc.) Find the supremum and infimum of the product of the areas of $\triangle A'BC$, $\triangle AB'C$, and $\triangle ABC'$ if:

1. Two sides of $\triangle ABC$ are parallel to sides of $\triangle A'B'C'$;
2. One side of $\triangle ABC$ is parallel to a side of $\triangle A'B'C'$;
3. No parallelism restriction is made.

Solution by Norman Miller, Queen's University, Kingston, Ontario.

Case 1. Take $A'B'\|AB$ and $B'C'\|BC$ (see Fig. 1). The $\triangle AB'C$, congruent to $\triangle ABC$, has unit area. The product ha (Fig. 1) is twice the area of $\triangle ABC$, which equals 2. The $\triangle A'BC$ is similar to $\triangle ABC'$, whence $x/a=h/AC'$ or $x\cdot AC'=ah$. Now the product of the three required areas is $(1)(\frac{1}{2}xa)(\frac{1}{2}h\cdot AC')$ $=\frac{1}{2}x\cdot AC'=\frac{1}{2}ah=1$. Hence as $A'C'$ rotates about B the product of the three areas remains constant.

Case 2. (See Fig. 2.) Take $B'C'\|BC$. Suppose first that $A'B'$ remains fixed in direction while $A'C'$ rotates about B. By the same argument as in Case 1 we have

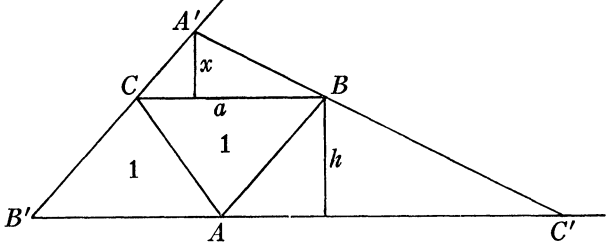

Fig. 1

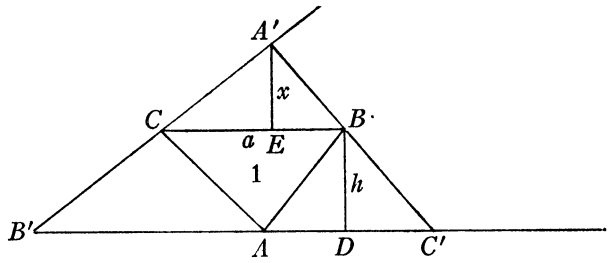

FIG. 2

the product of the areas of $\triangle A'BC$ and $\triangle ABC' = \frac{1}{2}x \cdot AC'$. Now $x/EB = h/DC'$, whence $x \cdot DC' = h \cdot EB$ or $x(AC' - AD) = h \cdot EB$. Hence $x \cdot AC' = x \cdot AD + h \cdot EB$. As $A'C'$ rotates so that C' recedes from A, $A' \to C$, AD and h are constant, $x \to 0$, and $EB \to a$. Hence $x \cdot AC' \to ha = 2$. It follows that the product of the areas of $\triangle A'BC$ and $\triangle AC'B$ approaches 1. Now when $A'B'$, through C, is allowed to take different positions, the product of the areas of the three required triangles can be made as small or as large as we please. Therefore the infimum $= 0$ and the supremum $= \infty$.

CASE 3. Since Case 2 is included in Case 3, the infimum for Case 2 cannot be less and the supremum cannot be greater than those for Case 3. Hence the required values here also are 0 and ∞.

Also solved by Yu Chang and Sidney Spital, M. A. Greening (Australia), Allan Wachs, and by the proposer.

A Known Sum

E 1902 [1966, 655]. *Proposed by David Shelupsky, the City College, New York*

Let $s(x) = \sum_{m=0}^{\infty} x^{2m+1}/1 \cdot 3 \cdot \cdots \cdot (2m+1)$. Prove that for all nonnegative x the inequality

$$e^{-x^2/2}s(x) < (\tfrac{1}{2}\pi)^{1/2}$$

holds, and that as $x \to +\infty$ the left-hand side is monotone increasing with the right-hand side as its limit.

Solution by D. C. B. Marsh, Colorado School of Mines. Since $s(x)$ satisfies $s'(x) = 1 + x \cdot s(x)$ with $s(0) = 0$, one may solve this linear equation routinely to find

$$e^{-x^2/2}s(x) = \int_0^x e^{-t^2/2}dt.$$

With positive integrand, the above integral is monotone increasing with non-negative x to the well-known limiting value of $\sqrt{\frac{1}{2}\pi}$.

Also solved by Donald Batman, M. A. Bershad, R. J. Bickel, D. A. Breault, Peter Bundschuh (Germany), P. R. Chernoff, W. O. Egerland, M. G. Greening (Australia), Eldon Hansen, J. Kuttler & N. Rubinstein & V. G. Sigillito & J. T. Stadter, Norman Miller, Senjanovic Pavao (Yugoslavia), Stanton Philipp, C. Riley, Michael Schulz, Richard Sinkhorn, Al Somayajulu, Stephen Spindler, Sidney Spital, V. K. Venkataraman, Charles Wexler, J. Ernest Wilkins, Jr., David Zeitlin, and the proposer.

Editorial Note. A Diophantine Equation

E 1904 [1966, 666]. *Proposed by D. L. Silverman, Beverly Hills, California*

Solve in positive integers: $x+y+z=xyz(x+2y-2z-2)$.

Solution by Michael Goldberg, Washington, D. C. From the given equation, $x+y+z$ is equal to xyz or a multiple of xyz. The only integral triplets satisfying this condition are (1, 1, 1), (1, 1, 2) and (1, 2, 3). By trial, the first two triplets yield no solution. The only permutation of the third that yields a solution is $x=1$, $y=3$, and $z=2$.

Also solved by Merrill Barneby, Robert Bart, D. A. Breault, Peter Bundschuh (Germany), P. R. Chernoff, H. M. W. Edgar, R. B. Eggleton (Australia), M. A. Fechter, W. V. Gamzon, Michael Goodman, M. G. ADVANCED PROBLEMS

Solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before April 30, 1968. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.

5520. *Proposed by T. J. Head, University of Alaska*

Let Λ be a ring with identity. A (left) Λ-module M is said to have a *projective cover* if there is a projective Λ-module P and a Λ-homomorphism $\phi: P\to M$ of P onto M for which the only submodule S of P satisfying $S+\ker(\phi)=P$ is $S=P$. Each projective Λ-module has a projective cover, namely the identity mapping of P onto P. For which rings Λ is it true that only the projective Λ-modules have projective covers?

5521. *Proposed by Harsh Pittie, Princeton University*

Prove that the automorphism group of D_n (the dihedral group of order $2n$) is isomorphic to the holomorph of Z_n (the integers, mod n).

5522. *Proposed by T. C. Brown, Kiev State University, U.S.S.R.*

Let S be a periodic semigroup whose idempotents lie in the center. Then the mapping $x \to x^{n(x)}$, where $x^{n(x)}$ is idempotent, is a homomorphism.

5523. *Proposed by J. T. Rosenbaum, University of Pittsburgh*

What pairs ϵ, θ, with $0 < \epsilon \leqq \theta < 1$, make the following statement true? If $\{E_n\}$ is any sequence of measurable subsets of $[0, 1]$, each with measure at least θ, there will exist a set of measure ϵ which is covered by E_n for infinitely many n. (Note. This is not implied by $|\overline{\lim} E_n| \geqq \epsilon$.)

5524. *Proposed by P. A. Schweitzer, Institute for Defense Analyses, Arlington, Va.*

Let d_n be the nth moment of the distance from a point P outside the unit circle to a randomly chosen point within the circle. Show that

$$d_n = R^n \cdot F\left(-\frac{n}{2}, -\frac{n}{2}, 2; \frac{1}{R^2}\right),$$

where $R > 1$ is the distance from P to the center of the circle, and F is the hypergeometric function.

Let e_n be the nth moment of the distance between two points chosen randomly within the unit circle. Show that

$$e_n = \frac{4}{(n+4)} F\left(-\frac{n}{2}, -\frac{n}{2}, 2; 1\right) = \frac{4(n+1)!}{(n+4)\Gamma(2+\frac{1}{2}n)^2}.$$

5525. *Proposed by Howard Kleiman, Queensborough Community College, New York*

Let p be a prime such that $2p+1$ is not a prime. Show that there is no cyclotomic polynomial of degree $2p$.

5526. *Proposed by R. O. Davies and Allan Hayes, The University, Leicester, England*

If P is due south of Q, then anyone travelling from P to Q on a Friday, without either crossing his own path or stopping, must at some instant be travelling due north. Discuss this assertion.

5527. *Proposed by F. Cunningham, Jr., Bryn Mawr College*

Prove that for every simple closed curve in 3-space there is a plane projection

of it having at least two double points (or a multiple point of order greater than two). Give an example of such a curve for which no plane projection has more than two double points (or one triple point).

5528. *Proposed by L. A. Steen, Saint Olaf College, Northfield, Minn.*

Let $\{D_i\}_1^\infty$ be a sequence of pairwise disjoint open disks contained inside the unit disk; let r_i denote the radius of D_i. Prove that

$$\sum_{i=1}^{\infty} r_i^2 < 1 \quad \text{whenever} \quad \sum_{i=1}^{\infty} r_i < \infty.$$

(In other words: Whenever you remove from the interior of the closed unit disk a sequence of pairwise disjoint open disks whose boundaries are of finite total length, the remaining set has positive Lebesgue measure.)

5529. *Proposed by D. S. Mitrinović, University of Belgrade, Yugoslavia*

Evaluate

$$\int_{-\infty}^{\infty} \prod_{j=1}^{n} \frac{\sin k_j(x - a_j)}{(x - a_j)}\, dx,$$

with k_j, a_j, $j=1, 2, \cdots, n$ real numbers.

SOLUTIONS OF ADVANCED PROBLEMS

Metrizable topologies on a Hausdorff Space

5396 [1966; 547]. *Proposed by Albert Wilansky, Lehigh University*

Find a set X and two normal and Hausdorff topologies T and T', for X, such that every T compact set is T' closed, but not every T' compact set is T closed.

Solution by H. W. Berkowitz, Rutgers, The State University. Example: Let X be the subset of the real line consisting of the closed unit interval and the point 2, i.e., $X = [0, 1] \cup \{2\}$. Let T' be the topology on X given by the usual euclidean metric. Let $T = \{A \subset X: 2 \notin A\} \cup \{A \subset X: 2 \in A \text{ and } X - A \text{ is countable}\}$, i.e., T gives the discrete topology to $[0, 1]$ and makes 2 a limit point of every set with a countable complement.

The compact sets of T are the finite sets, and these are T' closed. $[0, 1]$ is T' compact and is not T closed since 2 is a T limit point of $[0, 1]$. T' is certainly normal and Hausdorff. T is Hausdorff. T is normal since if A and B are T closed, disjoint subsets of X, then either A or B does not contain 2. Assume that A does not contain 2, then A is open and $X - A$ is open, $B \subset X - A$.

THEOREM. *Let X be a set with two topologies, T and T', which are Hausdorff and first countable. Assume every T compact set is T' closed. Then every T' compact set is T closed.*

Proof. Assume the conclusion does not hold. There exists $A \subset X$, where A is T' compact and not T closed. There exists $x \notin A$ such that x is a T limit point of A. There exists a sequence $\{a_i\} \subset A$ such that $\{a_i\}$ T converges to x. Hence $\{a_i\} \cup \{x\}$ is T compact, which implies $\{a_i\} \cup \{x\}$ is T' closed.

$\{a_i\} \subset A$ and A is T' closed, $x \notin A$ so $\{a_i\}$ is T' closed. Therefore, $\{a_i\}$ is T' compact which implies $\{a_i\}$ has a T' limit point in itself, call it a. There exists $\{b_i\}$ a subsequence of $\{a_i\}$ such that $\{b_i\}$ T' converges to a and $a \notin \{b_i\}$. Now $\{b_i\}$ T converges to x, so $\{x\} \cup \{b_i\}$ is T compact and hence T' closed. But $a \in \mathrm{Cl}[\{x\} \cup \{b_i\}]$ in T', a contradiction. Q.E.D.

We can obtain a stronger theorem than the one above, the proof of which is an application of Zorn's lemma.

DEFINITION. X is a *k-space* if a subset A of X is closed iff A intersects each compact set of X in a closed set. It is known that first countable Hausdorff spaces are k-spaces (see Kelley, "General Topology"). Then

THEOREM. *Let X be a set with Hausdorff topologies T and T' satisfying:* (i) *sets compact in T are closed in T',* (ii) *(X, T) is a k-space. Then every T' compact set is T closed.*

Also solved by S. P. Franklin, D. A. Hejhal, J. R. Isbell, F. E. Siwiec and the proposer.

Notes: Hejhal, Isbell and Franklin also observed that the two topologies cannot be simultaneously metrizable. Franklin refers to his paper "Spaces in which sequences suffice," *Fundamenta Mathematica* 57 (1965), pp. 107–116 for a wider application of the arguments involved. Isbell quoted the theorem on k-spaces as having been circulated by J. deGroot in 1965.

Rings without zero divisors

5420 [1966, 895]. *Proposed by T. P. Kezlan, University of Texas*

Suppose that R is a ring with no nonzero divisors of zero and with the property that every proper subring of R is finite. Prove that R is a field of prime characteristic.

Solution by E. A. Schreiner, Western Michigan University. By the hypothesis, R satisfies the cancellation laws. Thus, for $a \neq 0$, the mapping $r \to ar$ is one-one so card $(R) =$ card (aR). Since aR is a subring and proper subrings are finite, aR can not be a proper subring. Thus $a \neq 0$ implies $aR = R$. Similarly $a \neq 0$ implies $Ra = R$. Since the equations $ax = b$ and $ya = b$ are solvable for all $a \neq 0$, $b \in R$, R is a division ring. The characteristic of a division ring is either zero or a prime. Characteristic zero would imply the existence of an infinite proper subring isomorphic to the integers so that R must have prime characteristic.

If a is not in $Z(R)$, the center of R, then $A = \{x \in R \mid ax = xa\}$ is a proper, hence finite, subring containing all powers of a. Thus, $a^k = 1$ for some positive integer k and so $a^{k+1} = a$. Hence for every $x \in R$, there exists an integer $n(x) > 1$ such that $x^{n(x)} - x \in Z(R)$, that is, R is an H-ring (N. Jacobson, *Structure of Rings*, pp. 220–221) and therefore is commutative. Therefore R is a field of prime characteristic.

Crabtree, Jay DeMars, William Forman, E. R. Gentile, Marvin Gruber, G. A. Heuer, E. C. Hook, R. A. Howland, Kwangil Koh, C. M. Joiner & Stephen Price, E. S. Langford, Dorembus Leonard (Israel), Jiang Luh, C. F. Martin, M. D. Mavinkurve (India), Ka Menehune, Harry Miller, Joseph Oppenheim, Charles Riley, W. R. Scott, G. B. Seligman, Surjeet Singh (India), M. F. Smiley, L. R. Vermain (Australia), G. P. Weller, R. Wiegandt (Hungary), and the proposer.

Ed. Note: With their solutions, Scott and Seligman show that all infinite rings of the type described may be written $R=\cup_{n=1}^{\infty}\mathrm{GF}(p^{q^n})$, p, q primes.

The absolute value of a trigonometric type kernel

5421 [1966, 896]. *Proposed by D. J. Newman, Yeshiva University*

Evaluate

$$\int_0^{\infty}\left|\int_0^{\pi/2}\left(1-\frac{\sin xy}{\tan x}\right)dx\right|dy.$$

Solution by Naoki Kimura and Tetsundo Sekiguchi, University of Arkansas. Set $I(y)=\int_0^{\pi/2}[1-(\sin xy)/(\tan x)]dx$, $y\geqq 0$. Since

$$\lim_{y\to+\infty}\int_0^{\pi/2}\frac{x}{\tan x}\,\frac{\sin xy}{x}\,dx=\pi/2$$

by Dirichlet's theorem, we have

$$\lim_{y\to+\infty} I(y)=\pi/2-\pi/2=0. \tag{1}$$

By a simple computation, we have

$$I(y)-I(y+2)=\int_0^{\pi/2}(\cos xy+\cos x(y+2))dx=\frac{2}{y(y+2)}\sin\frac{\pi}{2}y. \tag{2}$$

Therefore, it follows for any positive integer N

$$I(y)-I(y+2N)=\sum_{n=0}^{N-1}\frac{2(-1)^n}{(y+2n)(y+2n+2)}\sin\frac{\pi}{2}y.$$

Since $I(y+2N)\to 0$ as $N\to+\infty$ by (1), we have

$$I(y)=\sum_{n=0}^{\infty}\frac{2(-1)^n}{(y+2n)(y+2n+2)}\sin\left(\frac{\pi}{2}\cdot y\right). \tag{3}$$

For any fixed $y\geqq 0$, the series (3) is an alternating series such that the sequence of the absolute values of the terms is decreasing. So the sign of $I(y)$ is the same as that of $\sin(\pi y/2)$. Thus

$$\begin{aligned} &I(y)>0 \quad \text{if } 4n<y<4n+2,\\ &I(y)<0 \quad \text{if } 4n+2<y<4n+4, \end{aligned} \qquad \text{where } n=0,1,2,\cdots, \tag{4}$$

$$\int_{4n}^{4n+4} |I(y)|\,dy = \int_{4n}^{4n+2} I(y)\,dy + \int_{4n+2}^{4n+4} (-I(y))\,dy \quad \text{by (4)}$$

$$= \int_{4n}^{4n+2} (I(y) - I(y+2))\,dy$$

$$= \int_{4n}^{4n+2} \frac{2}{y(y+2)} \sin\frac{\pi}{2} y\,dy \quad \text{by (2)}$$

$$= \int_{4n}^{4n+2} \frac{\sin(\pi/2)y}{y}\,dy - \int_{4n}^{4n+2} \frac{\sin(\pi/2)y}{y+2}\,dy$$

$$= \int_{4n}^{4n+2} \frac{\sin(\pi/2)y}{y}\,dy + \int_{4n+2}^{4n+4} \frac{\sin(\pi/2)y}{y}\,dy$$

$$= \int_{4n}^{4n+4} \frac{\sin(\pi/2)y}{y}\,dy.$$

Summing from $n=0$ to $n=N-1$ and letting $N\to\infty$ it follows that

$$\int_0^\infty |I(y)|\,dy = \int_0^\infty \left| \int_0^{\pi/2} \left(1 - \frac{\sin xy}{\tan x}\right) dx \right| dy = \frac{\pi}{2}.$$

Also solved by N. J. Fine, Emil Grosswald, E. L. Whitney, and the proposer.

Inequalities for the Riemann Zeta Function

5422 [1966, 896]. *Proposed by A. A. Mullin, University of California*

Let ζ be the Riemann zeta-function restricted to the real numbers. Prove the following: $\zeta(s-1)\cdot\zeta(2s) \geqq \zeta^2(s)\cdot\zeta(2s) \geqq \zeta^2(s) \geqq \zeta(2s)$, for $s>2$. Does one have in fact strict inequalities? Which, if any, of the following inequalities hold:

$$|\zeta(s-1)\cdot\zeta(2s)| \geqq |\zeta(s)|^2 \cdot |\zeta(2s)| \geqq |\zeta(s)|^2 \geqq |\zeta(2s)|$$

for the extension of ζ to $\operatorname{Re} s>2$?

Solution by Emil Grosswald, University of Pennsylvania.

A. All three inequalities are strict for $s>2$, the second one actually holds at least for $s>\frac{1}{2}$, the third one for $s>1$. Indeed, the first one may be written as

$$\sum_{n=1}^{\infty} \frac{\phi(n)}{n^s} = \frac{\zeta(s-1)}{\zeta(s)} > \zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s},$$

and is strict because the Euler function $\phi(n)$ satisfies $\phi(1)=\phi(2)=1$, $\phi(n)>1$ for $n\geqq 3$.

The second strict inequality is equivalent to the statement $\zeta(2s) = \sum_{n=1}^{\infty} n^{-2s} > 1$, which holds trivially for $s>\frac{1}{2}$.

The last inequality is

$$\sum_{n=1}^{\infty} \frac{d(n)}{n^s} = \sum_{n=1}^{\infty} \frac{n^s d(n)}{n^{2s}} = \zeta^2(s) > \zeta(2s) = \sum_{n=1}^{\infty} \frac{1}{n^{2s}},$$

where $d(n)$ is the number of divisors of n. Trivially, $n^s d(n) \geqq n^s \geqq 1$ with strict inequality for $s>0$ and $n>1$; hence, the inequality holds in $s>1$, the region of convergence of $\sum_{n=1}^{\infty} n^{-s} d(n)$.

B. Let $s=\sigma+it$; then only the first inequality holds for the extension of $\zeta(s)$ in $\sigma>2$. Indeed,

$$\left|\frac{\zeta(s-1)}{\zeta^2(s)}\right| = \prod_p \left|\frac{(1-p^{-s})^2}{1-p^{1-s}}\right| = \prod_p \left|(1-2p^{-s}+p^{-2s}) \sum_{m=0}^{\infty} \frac{p^m}{p^{ms}}\right|$$

$$= \prod_p \left|1 + \frac{p-2}{p^s} + \sum_{m=0}^{\infty} \frac{p^m(p-1)^2}{p^{(m+2)s}}\right| = \prod_p |1+\phi(p,s)|,$$

where $\phi(p, s) = ((p-2)/p^s) + (1-p^{-1})^2(1-p^{1-s})^{-1}$. Setting $\theta = t \log p$, we find for $p=2$, that $\operatorname{Re} \phi(2, s) = \frac{1}{4}(1-(\cos\theta/2^{\sigma-1})) > 0$. For $p \geqq 3$ it is determined that $\operatorname{Re} \phi(p, s) = A\{[p(p-2)(1-2p^{1-\sigma}\cos\theta + p^{2-2\sigma}) + (p-1)^2]\cos\theta + (p-1)^2 p^{\sigma-1}\}$ where A is a trivial, positive factor. It is easy to verify that the minimum is attained for $\cos\theta = -1$, so that, for $\sigma>2$,

$$\begin{aligned}(1/A)\operatorname{Re}\phi(p,s) &> p^{\sigma-1}(p-1) - [p(p-2)(1+p^{1-\sigma})^2 + (p-1)^2] \\ &> p(p-1)^2 - p(p-2)(1+p^{-1})^2 + (p-1)^2 \\ &= (p-1)^3 - p(p-2)(1+p^{-1})^2 \\ &= (p-1)^2[p-2-(2/p)-(1/p^2)] + (1+p^{-1})^2 > 0 \quad \text{for } p \geqq 3.\end{aligned}$$

Consequently, the real part of each factor exceeds unity and so does, *a fortiori*, its modulus, hence also the modulus of the product.

The second inequality does not hold in the half plane $\sigma>2$, but has to be replaced by the weaker one $|\zeta(2s)| > 2-\zeta(4) \cong .982$ (<1).

The last inequality does not hold either for complex $s=\sigma+it$, $\sigma>2$; one has instead $|\zeta(s)|^2 > \frac{2}{5}|\zeta(2s)|$.

Also solved by Charles R. Wall.

Expectation of a function of a sequence of zero's and one's

5423 [1966, 896]. *Proposed by James Singer, Brooklyn College*

Suppose that

$$u_n = \frac{1}{2^n} \sum_{(n)} \sum_{i=1}^{n} \frac{e_i}{2^{2i-s_i}},$$

where $e_i = 0$ or 1 for all i, $s_i = e_1 + e_2 + \cdots + e_i$, and the sum $\sum_{(n)}$ is extended over all possible allowable choices of $e_1, \cdots, e_n$; find a simple expression for u_n and $\lim_{n\to+\infty} u_n$.

I. *Solution by D. Ž. Djoković, Belgrade, Yugoslavia.* The set of all sequences $(e_1, \cdots, e_n)$ of zeros and ones such that $e_i = 1$ we shall denote by S_i. The set S_i is partitioned into i subsets $S_{ij} (j = 1, \cdots, i)$. The sequence $(e_1, \cdots, e_n)$ belongs to S_{ij} if and only if $e_i = 1$ and $s_i = j$. It is easy to see that S_{ij} contains exactly $2^{n-i}\binom{i-1}{j-1}$ sequences. Hence,

$$\begin{aligned} u_n &= \frac{1}{2^n} \sum_{i=1}^{n} \sum_{j=1}^{i} 2^{n-i} \binom{i-1}{j-1} \frac{1}{2^{2i-j}} \\ &= \sum_{i=1}^{n} \frac{1}{2^{3i-1}} \sum_{j=1}^{i} \binom{i-1}{j-1} 2^{j-1} \\ &= \frac{2}{3} \sum_{i=1}^{n} \left(\frac{3}{8}\right)^i = \frac{2}{5}\left(1 - \left(\frac{3}{8}\right)^n\right) \to \frac{2}{5} \quad (n \to +\infty). \end{aligned}$$

II. *Solution by N. J. Fine, The Pennsylvania State University.* The e_i may be regarded as independent random variables taking the values 0, 1 with probabilities $\frac{1}{2}, \frac{1}{2}$. Then $E(2^{e_i}) = \frac{3}{2}$, $E(e_i 2^{e_i}) = 1$, and

$$\begin{aligned} u_n &= E\left(\sum_{i=1}^{n} \frac{1}{2^{2i}} 2^{e_1} 2^{e_2} \cdots 2^{e_{i-1}} (e_i 2^{e_i}) \right) \\ &= \sum_{i=1}^{n} \frac{1}{2^{2i}} E(2^{e_1}) E(2^{e_2}) \cdots E(2^{e_{i-1}}) E(e_i 2^{e_i}) \\ &= \sum_{i=1}^{n} \frac{1}{2^{2i}} \left(\frac{3}{2}\right)^{i-1} = \frac{2}{5}\left(1 - \left(\frac{3}{8}\right)^n\right) \\ &\to \frac{2}{5}. \end{aligned}$$

Also solved by S. T. M. Ackermans (Netherlands), Duane W. Bailey, D. M. Bloom, Paul Brock, Yu Chang & Sidney Spital, Miltiades Demos, J. G. Deutsch, Jerry Fischer, William Forman, G. A. Heuer, A. G. Konheim (Germany), D. A. Marcus, Steven Minsker, C. B. A. Peck, F. W. Steutel (Netherlands), Jeffrey Tollefson, Dieter Wolke (Germany), and the proposer.

A general relation of Ramanujan

5424 [1966, 896]. *Proposed by Van E. Wood, Battelle Memorial Institute*

The relation of Ramanujan

$$\text{(A)} \qquad \int_0^\infty \frac{e^{-yx}}{x(\pi^2 + \ln^2 x)}\, dx = e^y - \int_0^\infty \frac{y^x}{\Gamma(1+x)}\, dx, \qquad y \geqq 0$$

is readily verified by the Laplace transform method (G. H. Hardy, *Ramanujan* University Press, Cambridge, 1940, p. 196). Ramanujan, who, according to Hardy, disliked contour integration, proved (A) indirectly by discovering a generalization, the correctness of which could be shown without using integration in the complex plane. Show that (A) can be verified directly (that is, with-

out finding a more general integral of which it is a special case) by a method which does not involve contour integration.

Solution by R. E. Shafer, Lawrence Radiation Laboratory, University of California.

$$\int_0^\infty x^{\xi-1}e^{-zx}\left(\cos \pi\xi - \frac{\sin \pi\xi}{\pi}\cdot \log x\right)\cdot\frac{dx}{\pi^2 + \log^2 x} = e^z - \int_{-\xi}^\infty \frac{z^x}{\Gamma(1+x)}\,dx$$

for $\mathrm{Re}(\xi)\geqq 0$, $|\arg z| < \pi/2$. We note that

$$E_{1-\nu}(z) = \frac{\Gamma(\nu)}{z^\nu} - e^{-z}\cdot\left[\frac{1}{\nu} + \frac{z}{\nu(\nu+1)} + \frac{z^2}{\nu(\nu+1)(\nu+2)} + \cdots\right]$$

$$= \frac{e^{-z}}{\Gamma(1-\nu)}\int_0^\infty \frac{e^{-x}x^{-\nu}}{z+x}\,dx, \qquad |\arg z| < \pi,\ \mathrm{Re}\,(\nu) < 1.$$

The right hand expression may be replaced by

$$\int_{-\xi}^{-\xi+1} e^z\cdot z^\nu E_{1-\nu}(z)\,\frac{d\nu}{\Gamma(\nu)} = \int_{-\xi}^{-\xi+1}\left[e^z - \sum_{n=0}^\infty \frac{z^{\nu+n}}{\Gamma(1+\nu+n)}\right]d\nu$$

$$= \frac{1}{\pi}\int_0^\infty \frac{e^{-x}}{z+x}\,dx\cdot\int_{-\xi}^{-\xi+1} \sin \pi\nu\cdot e^{\nu \log z/x}\,d\nu$$

$$= \int_0^\infty \frac{e^{-x}}{(\log^2 z/x + \pi^2)}\,(z/x)^{-\xi+1}\left\{\cos \pi\xi + \frac{\sin \pi\xi}{\pi}\log z/x\right\}\frac{dx}{z}$$

for $|\arg z| < \pi$, $\mathrm{Re}\,(\xi)\geqq 0$ which leads to the desired result.

Also solved by the proposer.

A nonnegative definite matrix

5425 [1966, 896]. *Proposed by V. R. R. Uppuluri, Oak Ridge National Laboratory*

Let A and B be two real, symmetric, positive definite matrices. Show that $C=2A(A+B)^{-1}A+2B(A+B)^{-1}B-(A+B)$ is a nonnegative definite matrix.

I. *Solution by Wallace Givens, Oak Ridge National Laboratory.* Since $A+B>0$, $A+B=(T'T)^{-1}$ so

$$C = 2AT'TA + 2BT'TB - (T'T)^{-1} = T^{-1}[2P^2 + 2Q^2 - 1](T')^{-1},$$

where $P=TAT'$ and $Q=TBT'$ so $P+Q=1$. Hence, $TCT'=2P^2+2(1-P)^2-1 = (2P-1)^2$ is nonnegative definite so C is also nonnegative definite.

II. *Solution by Ingram Olkin, Stanford University, and A. W. Marshall, Boeing Scientific Research Laboratories.* If $X: p\times n$, $M: n\times n$, and $M\geqq 0$ (positive semi-definite), then the function $f(X)=XMX'$ is convex, i.e.,

$$(1) \qquad (\alpha X + \beta Y)M(\alpha X + \beta Y)' \leqq \alpha XMX' + \beta YMY',$$

where $0 \leqq \alpha \leqq 1$, $\alpha+\beta=1$, and $A \leqq B$ means that $B-A \geqq 0$. The proof of (1) is obtained by observing that (1) is equivalent to

$$(2) \qquad 0 \leqq \alpha\beta(X - Y)M(X - Y)'.$$

Applying (1) to $M=(A+B)^{-1}$, $X=A$, $Y=B$, $\alpha=\frac{1}{2}$, we obtain $A(A+B)^{-1}A + B(A+B)^{-1}B \geqq (A+B)/2$, which solves the problem. Note that we have used $A+B>0$ (positive definite), but do not require $A>0$, $B>0$.

An immediate generalization of (1) is $(\sum_1^k \alpha_j X_j)M(\sum_1^k \alpha_j X_j') \leqq \sum_1^k \alpha_j (X_j M X_j')$, $0 \leqq \alpha_j$, $\sum \alpha_j = 1$. Thus, for $M = \sum_1^k A_j > 0$, $X_j = A_j$, we obtain

$$\sum_1^k A_j \left(\frac{A_1 + \cdots + A_k}{k}\right)^{-1} A_j \geqq \frac{A_1 + \cdots + A_k}{k}.$$

III. *Solution by Marvin Marcus, University of California at Santa Barbara.* In a forthcoming paper (*An inequality for linear transformations*) the following result is proved: if H and K are positive definite hermitian transformations on a unitary space V and x and y are arbitrary vectors then

$$(1) \qquad (H^{-1}x, x) + (K^{-1}y, y) \geqq ((H + K)^{-1}x + y, x + y).$$

Now set $x=Au$, $y=Bu$, $H=K=A+B$ and (1) becomes

$$(A(A + B)^{-1}Au, u) + (B(A + B)^{-1}Bu, u) \geqq ((2(A + B))^{-1}(A + B)u, (A + B)u)$$

which immediately simplifies to the desired inequality. Note that A and B can be assumed positive-definite hermitian.

IV. *Solution by M. F. Neuts, Purdue University.* Clearly $A+B$ is real, symmetric and positive definite. Writing $(A+B)(A+B)^{-1}(A+B)$ for the last term in C, expanding and regrouping, we obtain

$$C = (A - B)(A + B)^{-1}(A - B)$$

and since $A-B$ is symmetric, the result is now obvious. If $A-B$ is nonsingular, then C is positive definite.

V. *Solution by Duane W. Bailey, Amherst College.* This result is a particular case of a more general theorem. A Banach *-algebra $\mathfrak{A}$ with continuous involution $x \to x^*$ is said to be *symmetric* if $\mathrm{Sp}(x^*x) \subset [0, \infty)$ for each $x \in \mathfrak{A}$. (See Rickart, *General Theory of Banach Algebras* for the facts about these algebras used below.) A linear functional f on $\mathfrak{A}$ is *positive* if $f(x^*x) \geqq 0$ for all $x \in \mathfrak{A}$. If $x \in \mathfrak{A}$ is self-adjoint ($x^*=x$) we use the notation $x \geqq 0$ to mean $\mathrm{Sp}(x) \subset [0, \infty)$, and similarly for $x>0$.

THEOREM. *If a and b are self-adjoint elements of a symmetric Banach *-algebra $\mathfrak{A}$, and if $a>0$, $b>0$, then $c=2a(a+b)^{-1}a+2b(a+b)^{-1}b-(a+b)$ satisfies $c \geqq 0$.*

Proof. Let f be a positive functional on $\mathfrak{A}$. Then

$$f(a) = f((a+b)(a+b)^{-1}a) = f(a(a+b)^{-1}a) + f(b(a+b)^{-1}a)$$
$$f(b) = f((a+b)(a+b)^{-1}b) = f(a(a+b)^{-1}b) + f(b(a+b)^{-1}b).$$

Hence,

$$\begin{aligned} f(c) &= f(2a(a+b)^{-1}a) + f(2b(a+b)^{-1}b) - f(a) - f(b) \\ &= f(a(a+b)^{-1}a) + f(b(a+b)^{-1}b) - f(b(a+b)^{-1}a) - f(a(a+b)^{-1}b) \\ &= f((a-b)(a+b)^{-1}a) - f((a-b)(a+b)^{-1}b) \\ &= f((a-b)(a+b)^{-1}(a-b)). \end{aligned}$$

Because $\mathfrak{A}$ is symmetric, $a>0$ and $b>0$ imply $(a+b)>0$ and $(a+b)^{-1}>0$. It follows that $(a+b)^{-1}$ has a self-adjoint square root $h^2=(a+b)^{-1}$. Consequently,

$$f(c) = f((a-b)(a+b)^{-1}(a-b)) = f((h(a-b))^*(h(a-b)) \geqq 0$$

from the positivity of f. Again, by the symmetry of $\mathfrak{A}$

$\mathrm{Sp}(c) \subseteq \{f(c) \mid f \text{ a positive functional on } \mathfrak{A}\} \subseteq [0, \infty)$. Thus $c \geqq 0$.

The required result is an immediate consequence of the theorem because the (Banach) algebra of $n \times n$ matrices is symmetric and the notions of positivity and nonnegativity coincide with those above.

The theorem as stated applies, in addition, to the algebra of all bounded linear operators on a Hilbert space as well as to the group algebras of many locally compact groups.

Joiner & Stephen Pierce, E. L. Koh, A. W. Marshall, M. D. Mavinkurve (India), W. L. Morris, Ingram Olkin, F. W. Pontig (England), Stanislaw Sedziwy (Poland), Barry Simon, Robert Singleton, M. F. Smiley, Olga Taussky, H. R. van der Vaart, Nolan Wallach, J. E. Wilkins, Jr., J. P. Williams and the proposer.

Simply-connecting a topological space

5426 [1966, 896]. *Proposed by Omar Khayyam, Jr., University of California, Berkeley.*

Prove or disprove: Every topological space X can be embedded in a simply-connected space X^* where X^* is obtained from X by the adjunction of one point.

Solution by W. O. Alltop, Naval Ordinance Test Station. The statement in question is true. Suppose X is a topological space with topology T. Let $X^* = X \cup \{p\}$ where $p \notin X$. Let $T^* = \{\phi\} \cup \{U \cup \{p\} : U \in T\}$. Then the space X is imbedded in the space X^* with topology T^*. We claim that X^* is simply-connected.

Suppose a and b are two points of X^*. Let $f: I \to X^*$ be defined as follows: $f(0)=a, f(1)=b, f(t)=p$ for $0<t<1$. Now f is a path in X^* from a to b. Thus, X^* is path-wise connected.

Now suppose f and g are two paths in X^* from a to b. We define $H: I \times I \to X^*$

as follows: $H(t, 0)=f(t)$, $H(t, 1)=g(t)$, $H(0, u)=a$, $H(1, u)=b$, $H(t, u)=p$ elsewhere. H is a fixed endpoint homotopy between f and g, so f and g are homotopically equivalent with respect to their endpoints. Thus, X^* is indeed simply-connected.

Also solved by S. L. Bloom, M. D. Mavinkurve (India), G. L. Porter and the proposer.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto 5, Canada. Correspondence about Reviews will be welcome.

Linear Transformations and Matrices. By F. A. Ficken. Prentice-Hall, Englewood Cliffs, N. J., 1967. xii+398 pp. $10.95.

This book gives an excellent presentation of the basic theory of finite-dimensional real and complex linear spaces. Although the prerequisites are no more than standard high school mathematics, the level of sophistication of the treatment would probably make this book more suitable as a text at the Junior-Senior level than for the Mathematics 3 course proposed by the CUPM in "A General Curriculum in Mathematics for Colleges." Also it would probably take an extremely able class to do justice to this book in less than a standard two semester course.

The first four chapters give a brief survey of background material on such items as sets, the system of real numbers, vectors in three-dimensional Euclidean space, groups, and fields. This is a fairly rapid development, and many results are stated without proofs. The chapter on vectors in three-dimensional space is excellent and should be considered indispensable for providing motivation for definitions and theorems studied later.

In Chapter 5 linear spaces are formally introduced, and the remainder of the book is concerned with linear transformations, linear functionals, duality, basic matrix theory, systems of linear algebraic equations, bilinear and quadratic functionals and forms, determinants, similar operators, and unitary and Euclidean spaces. The book contains a more thorough treatment of duality than do many conventional texts. Since the author is assuming the reader has a limited background in algebra, some topics, such as the rational canonical form for a matrix, receive but brief mention.

There is an ample supply of problems of all shades of difficulty and theoretical importance, with solutions or hints for solution of many of these given.

P. W. CARRUTH, Middlebury College

Mathematical Methods in the Physical Sciences. By Mary L Boas. Wiley, New York, 1966. xix+778 pp. $11.95.

During the last twenty years there have been many books published under the general title, "Advanced mathematics for engineers," or similar titles. The purpose of these books is to give the student of engineering, physics, or chemistry a basic competence in the many areas of mathematics that he will use in his chosen field. Of the various books of this type that have been published in the last ten years, this is one of the best.

This book provides coverage that includes nearly every area of mathematical physics needed in the junior, senior, and first year of graduate work. The book is divided into

fifteen chapters. The subjects covered include: infinite series, complex numbers, determinants and matrices, partial differentiation and multiple integrals, vector analysis, Fourier series, ordinary differential equations, calculus of variations, special functions, coordinate transformations and tensor analysis, functions of a complex variable, orthogonal polynomials and functions, the Laplace and the Fourier transforms, partial differential equations, and probability.

The author has presented the elements of the various topics enumerated above with unusual clarity. Each chapter is concluded with a large number of problems extremely well chosen to illustrate the various topics discussed. Answers are given to most of the problems proposed in the text. The author has used original approaches to the presentation of many topics; one of the best is the development of Stirling's approximate formula for the factorial by the use of the gamma function.

A suggestion that may make the book more valuable for the students for whom it is intended, would be that in the next edition the author might add a more comprehensive discussion of linear differential equations expressed in matrix notation and also add a chapter on nonlinear differential equations.

L. A. PIPES, University of California, Los Angeles

The Role of Mathematics in the Rise of Science. By Salomon Bochner. Princeton University Press, Princeton, N. J., 1966. x+386 pp. $9.00.

It is not often that a distinguished mathematician takes the trouble of digging deeply into the history of his subject and for this reason alone this book should be welcomed. The history of science has gradually become an accepted academic subject, and many young and analytic minds have devoted themselves to research in this field. In the process history of science has grown in depth, together with its philosophy. This again is a challenge to those who themselves have contributed to the advance of modern science. Bochner offers his expositions not only with great mastery of the literature, but also, in the tradition of Heiberg and Dyksterhuis, with the erudition of a classical scholar.

The book is composed of a series of eight essays in which several aspects of mathematics are investigated in regard to their origin and often in relation to the natural sciences. The book, states the author, is about the uniqueness of mathematics as a force of our intellectuality and about the mystique of its creativity, about the growing efficacy of mathematics, its widening importance, and its continuing spread. The author allows himself to wander widely in these green pastures, admiring, probing and criticizing while explaining some of the achievements of the present and of yesteryear. A recurrent theme is the comparison of Greek mathematics with that of the seventeenth century and later. One essay is a highly specialized study of some of the fundamental concepts in Aristotle's physics seen in the light of today, in which somewhat of a limited rehabilitation of the Stagirite is—and I think successfully—attempted. Another essay concerns the role of mathematics in the rise of physics, another tries to establish the nature of mathematics. Seventy three pages are devoted to showing how history of science differs from other history. The last two essays are entitled "The essence of mathematics" and "The essence of analysis." The book ends with a great number of sometimes critical biographical sketches, "in lieu of an Epilogue."

In the course of these three hundred pages the author deals with so many subjects and expresses so many opinions that it is difficult to do him justice in a short review. The reader must find out for himself, but he better read up first a little on the history of mathematics in a less sophisticated book. He then can try to match his wits with those of the author, and be struck by an interesting or novel fact or idea, be perhaps a little amazed on occasion, and may find himself agreeing here and disagreeing there.

Let me give some examples from my own reading of the book. I followed with considerable profit Bochner's analysis of some concepts in Aristotle's physics, and especially was struck by his analysis of the concept of space (topos) and by his contention that

Aristotle's opposites such as cold and hot, dry and moist, are more appropriate to nineteenth century thermodynamics than to seventeenth century mechanics (p. 166). There is also some Aristotelianism in modern neurology. On the other hand, I believe that Bochner underestimates the possibility of using sociological concepts to explain trends in mathematics such as the growth and decay of Greek mathematics, or the concentration of the eighteenth century mathematicians on mechanics (p. 7). I can agree with his opinion that, with all respect for the usefulness of medieval studies, there exists a peculiar danger of overromanticizing the Middle Ages in so far as the history of science is concerned (p. 60). But when he writes (p. 109) that Stevin "appears on the scientific stage rather abruptly, as if from nowhere," then I fail to follow him, since the engineer-mathematician-accountant is rather a typical figure of the Renaissance. I also profit by the analysis of the meaning of the three dimensionality of space in the mathematical laws of physics (p. 248)—it reminds me of some ideas that intrigued Ehrenfest—but when Bochner says (p. 87) that it is questionable whether it is meaningful to force Heraclitus' sayings into any kind of "theory," then I must remark that Hegel did exactly that, and I, for one, consider Hegel's "theory" very meaningful indeed. I could go on like this, but these examples will show the richness of the material presented in this book. The reader is in for a treat, and we hope to see more essays from Bochner on the history of science.

D. J. STRUIK, Massachusetts Institute of Technology

Generalized Functions, Volume I. Properties and Operations. By I. M. Gel'fand and G. E. Shilov; translated from Russian by Eugene Saletan. Academic Press, New York 1964. xviii+423 pp. $13.50.

Since several reviews of this book have appeared since its first Russian edition in 1958, this review will essentially be a summary of the contents of the book. Chapter I: basic introduction to generalized functions, their convergence, differentiation and integration, convolutions of generalized functions, applications to solutions of differential equations; Chapter II: Fourier transforms of generalized functions of one or more variables and applications to differential equations. Chapter III: special types of generalized functions. Four appendices one of which gives additional details on generalized functions of one or more complex variables.

In the opinion of the reviewer, this book, contrasted with L. Schwartz's "Théorie des distributions" does not invoke the duality theory in locally convex spaces and is tremendously analytical in approach. A major feature of the book is that it has great details on several special types of generalized functions and their applications.

M. S. RAMANUJAN, University of Michigan

Computing Methods, Vols. I and II. By I. S. Berezin and N. P. Zhidkov. Addison Wesley, Reading, Mass., 1965. Vol. I, xxxiv+464 pp. $15.00; Vol. II, xv+678 pp. $15.00.

These two volumes constitute a laboriously detailed, stingily referenced, minimally exercise-endowed, exhaustive (and exhausting), largely theoretical account of numerical solution methods for the following general problem areas: interpolation; integration; polynomial and (generalized) Fourier series approximations; (systems of) linear, high degree algebraic, and transcendental equations; eigen-values and -vectors; and ordinary and partial differential equations. For each problem area, many direct, iterative, and variational solution techniques are presented; each technique is accompanied by its functional analytic basis and relevant discussions of error, convergence, and stability.

Nearly all of the method presentations of the book are in the classic static-factual mode rather than the dynamic-procedural mode more appropriate to modern computing practice. The task of converting factually-described methods into working algorithms is left entirely to the reader, as is the task of relating discussions of error, convergence, and stability of methods to the algorithmic expression of those methods.

Analysis

Exercises in Mathematics. By J. Bass. Translated by Scripta Technica. Academic Press, New York, 1966. xii+459 pp. $14.75. Solved problems in integration, series, Fourier series and integrals, analytic functions, ordinary and partial differential equations. S, P.

Introduction to Approximation Theory. By E. W. Cheney. McGraw-Hill, New York, 1966. xii+259 pp. $10.95. In order to "bring a large segment of approximation theory within the comfortable grasp of undergraduate and beginning graduate mathematics students," this book pre-supposes knowledge of such topics as sequences, vector spaces, series, uniform convergences, continuity, and the mean-value theorem, but not complex functions, modern algebra, Lebesgue integration or measure theory. Topics include Tchebycheff solution of inconsistent linear equations, Tchebycheff approximation, least-squares approximation, rational approximation, the Stone approximation theorem, the Müntz theorem, the converses of the Jackson theorems, polygonal approximation and bases, the Kharshiladze-Lozinski theorems and approximation in the mean. There are extensive historical notes and a substantial bibliography intended "to restore some of the historical prospective which is inevitably lost when the subject is presented in the dry manner of a *fait accompli*," T (16–17), S, P, L.

Problems and Solutions in Mathematical Physics. By Y. Choquet-Bruhat. Translated by C. Peltzer. Translation editor J. J. Brandstatter. Holden-Day, San Francisco, 1967. 314 pp. $9.00. In spite of the title, this is actually a collection of problems in linear algebra, linear analysis, function spaces, and differential and integral operators—and hence of use in courses in these fields. The title reflects the author's desire to make mathematics useful to practitioners rather than an especially physical content. S (14–16), P.

Advanced Calculus. By Jane Cronin-Scanlon. Heath, Boston, 1967. ix+320 pp. $8.50. Real numbers and euclidean n-space, continuous and differentiable functions, integration theory (Riemann and Lebesgue), infinite series of functions (including Fourier series), curves, surfaces and integrals on them. "The main emphasis is on the development of understanding of mathematical theory rather than a description of methods for solving particular problems." T (15–16).

Introduction to the Theory of Alegbraic Numbers and Functions. By Martin Eichler. Translated by George Striker (Göttingen). Academic Press, New York, 1966. xiv+323 pp. $14.50. A unified treatment of classic fields to which Kronecker, Dedekind, and Emmy Noether made essential contributions and which played a very significant role in the development of mathematics during the last 100 years. P, L.

Linear Systems of Ordinary Differential Equations with Periodic and Quasi-Periodic Coefficients. By Nikolay P. Erugin. Translated by Scripta Technica, (with revisions by the author for the English edition). Translation editor Richard Bellman. Academic Press, New York, 1966. xxi+271 pp. $12.00. Existence proofs and methods of constructing solutions. P.

Generalized Functions. Vol. 5. Integral Geometry and Representation Theory. By I. M.

Gelfand, M. I. Graev and N. Ya. Vilenkin. Translated by Eugene Saletan. Academic Press, New York, 1966. xvii+449 pp. $17.00. This volume in the series "uses the theory of generalized functions to discuss the Radon and other integral transforms on real and complex spaces." P.

Fundamentals of Abstract Analysis. By Andrew M. Gleason. Addison-Wesley, Reading, Mass. 1966. xi+404 pp. $13.75. Based on a nonaxiomatic formulation, this fine book explains the relation of set theory to mathematics. "It is a very abstract and highly formalistic book, but in several strategic places I have tried to point out how formalism is related to the elusive 'real mathematic' which exists only in our intuition." Sets, logic, configurations, equivalence, order induction, fields, real numbers, complex numbers, counting and size of sets, limits, sum and products, topology of metric spaces, analytic function. Very favorably reviewed by M. Hestenes in *Science*, 3 March, 1967. T (15–17).

An Introduction to Sequences, Series, and Improper Integrals. By O. E. Stanaitis. Holden-Day, San Francisco, 1967. vii+210 pp. $7.95. Based on experience teaching college sophomores and high school teachers, this introduction includes uniform convergence, trigonometric series, and improper integrals. T (14), S.

Applied Differential Equations, 2nd ed. By Murray R. Spiegel. Prentice-Hall, Englewood Cliffs, N. J., 1967. xv+412 pp. $8.50. This well-known text has been revised by adding sections on the Laplace transform, the Runge-Kutta method of numerical solution, Fourier-Bessel series and orthogonal functions, a discussion of linear dependence, and some additional exercises. T (14–15).

Applications

Stability of Motion. By A. M. Liapunov. Translated by Flavian Abramovici and Michael Shimshoni. Academic Press, New York, 1966. xi+203 pp. $9.75. S. Lefschetz ends his preface as follows: ". . . this volume offers a welcome addition to the growing literature centering around Liapunov's classical stability theory and available to the non-Soviet world." Three papers by Liapunov, a preface to one of them, a paper by V. A. Pliss, all previously unavailable and virtually unknown in English. P, L.

Applications of Undergraduate Mathematics in Engineering. Written and edited by Ben Noble. Mathematical Association of America, Macmillan, New York, 1967. xvii+364 pp. $9.00. Based on a selection from 200 contributions by engineers in industry and education to the Commission of Engineering Education and the Committee on the Undergraduate Program in Mathematics. An important contribution to collegiate education. S (13–16), P, L.

Geometric Programming—Theory and Application. By Richard L. Duffin, Elmor L. Peterson, and Clarence Zener. Wiley, New York, 1967. xi+278 pp. $12.50. A "new mathematical discipline" for dealing with nonlinear optimization problems by using concepts from linear geometry. P.

Vehicular Traffic Science. Proceedings of the Third International Symposium on the Theory of Traffic Flow, New York, June 1965, held under the Auspices of the Transportation Science Section of the Operations Research Society of America. Edited by Leslie C. Edie (The Port of New York Authority) and Robert Herman and Richard Rothery (Dept. of Theoretical Physics Research Laboratories, General Motors Corporation). American Elsevier, New York, 1967. x+373 pp. $16.00. Forty-five papers

devoted to "statistical and mathematical understanding," largely via stochastic models and optimum problems. P.

Shift Register Sequences. By Solomon W. Golomb, with portions co-authored by Lloyd R. Welch, Richard M. Goldstein, and Alfred W. Hales. Holden-Day, San Francisco, California, 1967. xiv+224 pp. $7.95. First in a series on information systems edited by Norman Abramson, this volume is intended to make available all information required for instruction and applications by those interested in coding theory, switching theory, and finite automata. T (17), S, P.

Digital Simulation in Operational Research. A conference under the aegis of the Scientific Affairs Division of NATO. Edited by S. H. Hollingdale. American Elsevier, New York, 1967. 392 pp. $14.50. Papers on theory and applications to linguistics, industry, warfare, S, L.

Algebraic Linguistics; Analytical Models. By Solomon Marcus. Academic Press, New York, 1967. xi+254 pp. $12.00. Analysis of language as a collection of sentences, axiomatic theory, linguistic origins, applications to natural languages. P, L.

Theory of Games. Techniques and applications. The proceedings of a conference under the aegis of the NATO Scientific Affairs Committee at Toulon, 29th June-3rd July, 1964. Edited by A. Mensch. American Elsevier, New York, 1966. 490 pp. $15.00. "The main problem was this—could the Theory of Games, which had been introduced as a means of simplifying human problems, be applied to military problems, both tactical and strategic? . . . For reasons of security, certain papers . . . have not been included." P.

Mathematics of Physics and Modern Engineering. By I. S. Sokolnikoff and R. M. Redheffer. 2nd ed. McGraw-Hill, New York, 1966. x+752 pp. $10.95. New material, some major revisions, and more exercises. Chapters (designed to be independent): Infinite series, Nonlinear differential equations, Linear differential equations and Laplace transform, Algebra and geometry of vectors; matrices, Functions of several variables, Field theory, Partial differential equations, Complex variable, Probability, Numerical analysis. The authors feel that they have included what "should be the minimum mathematical equipment of a scientific engineer" in sufficient detail to require "six consecutive semester courses meeting three hours a week" following "a sound first course in calculus." T(14–16).

Geometry

Resolution of Singularities of Embedded Algebraic Surfaces. By Shreeram Shankar Abhyankar. Academic Press, New York, 1966. ix+291 pp. $13.50. The primary aim is a self-contained exposition of "the marvelous memoir of Zariski entitled: Reduction of singularities of algebraic three-dimensional varieties" (*Annals of Mathematics* (2) 40 (1939) 639–689). A secondary aim is to partially extend some of the results to nonzero characteristics. P.

Differential Geometry. By Louis Auslander. Harper and Row, New York, 1967. xii+271 pp. $10.95. This treatment of differential geometry of surfaces "combines both the modern and classical approaches." Prerequisites are "about one year of modern algebra and two years of calculus." After algebraic preliminaries on vector spaces, topics are differentiable structures, matrix Lie groups and frame bundles, differential invariants, local theory of surfaces, global study of surfaces, integration of forms and the Gauss-Bonnet theorem. T (15–16).

The Method of Coordinates. By I. M. Gelfand, E. G. Glagoleva, and A. A. Kirillov. Translated and adapted from the Russian by Leslie Cohn and David Sookne. Prepared under the auspices of the Survey of Recent East European Mathematical Literature, a project conducted by Alfred L. Putnam and Izaak Wirszup, University of Chicago, under a grant from the National Science Foundation. Library of School Mathematics. Vol. I. The M. I. T. Press, Cambridge, Mass., 1967. viii+69 pp. $1.50 (paper). "Elementary" analytic geometry by masters. Part one deals with one, two, and three dimensions, part two with four-dimensional space. T(13), S, P, L.

Plane Geometry and its Groups. By Heinrich W. Guggenheimer. Holden-Day, San Francisco, 1967. xii+288 pp. $8.50. ". . . an attempt to revitalize the study of elementary geometry within the framework of modern mathematics." Generation of motions by reflections, geometry and the meta-mathematics of geometry. T (15–16), TT, S, P, L.

Geometric Transformations. Vols. I and II. By P. S. Modenov and A. S. Parkhomenko. Translated from the Russian by Michael B. P. Slater. Academic Press, New York, 1965. Vol. I: x+160 pp. Vol. II: xi+136 pp. (paper) $2.45. Orthogonal (59 pp), similarity (20 pp), affine (55 pp), and projective transformations (110 pp), inversions (14 pp). Not recommended as a text or supplement for students (because of a largely antiquated point of view and often careless exposition) but useful as a quarry for experts. P.

Lectures on the Foundations of Geometry. By A. V. Pogorelov. Translated from the second Russian edition by Leo F. Boron with the collaboration of Ward D. Bouwsma. Noordhoff, Groningen, Netherlands, 1966. 137 pp. $6.90. Historical sketch, axioms of Euclidean geometry, Lobachevskian geometry, projective geometry. T (14–15), TT, S, P. L.

Geometric Exercises in Paper Folding. By T. Sundara Row. Edited and revised by Wooster Woodruff Beman and David Eugene Smith. Dover, New York, 1966. xii+148 pp. $1.00 (paper). A reprint of the classic 2nd ed. of 1905 which saw the light of day due to the interest of Felix Klein, W. W. Beman, and David Eugene Smith. It has long been difficult to obtain and will now bring much pleasure to people, young and old, at many levels of sophistication. S, P, L.

Projective Geometry, Vols. I and II. By Oswald Veblen and John Wesley Young. Blaisdell, Waltham, Mass., Vol I (1938): x+345 pp. $2.25 (paper). Vol. II (1946): x+511 pp. $3.00 (paper). Reprint of a great classic and reference work. S, P, L.

Probability and Statistics

An Introduction to Stochastic Processes With Special Reference to Methods and Applications. By M. S. Bartlett. 2nd ed., Cambridge University Press, 1967. xvi+362 pp. $9.50. This compact, comprehensive treatise is designed for the applied mathematician, statistician, engineer, biologist, economist, etc., rather than for the "pure-minded mathematical critic" who may find it unsatisfactory for purposes not intended by the author. The second edition differs by the addition of sections on new developments. S, P.

Stationary and Related Stochastic Processes. Sample Function Properties and their Applications. By Harald Cramer and M. R. Leadbetter. Wiley, New York, 1967. xii+348 pp. $12.50. An outcome of collaboration sponsored by NASA from 1962. Assumes modern probability theory. P, L.

Queuing Theory, Recent Developments and Applications. A conference, under the aegis of the NATO Science Committee, September 27th-October 1965. Edited by R. Cruon. American Elsevier, New York, 1967. 224 pp. $13.50. P.

Fundamentals of Applied Probability Theory. By Alvin W. Drake. McGraw-Hill, New York, 1967. xi+283 pp. $9.75. ". . . from a relatively physical, applied point of view. . .", assuming a course in calculus. T (14–15).

Discrete Probability. By R. A. Gangolli and Donald Ylvisaker. Harcourt, Brace & World, New York, 1967. xii+223 pp. $4.50 (paper). This book is intended for an elementary one semester course. It is one of the Harbrace College Mathematics Series of single-topic textbooks to provide compact units and supplementary material. The reasonable price commends it for serious consideration to anyone planning a course of this kind. T (14–15).

Denumerable Markov Chains. By John G. Kemeny, J. Laurie Snell, and Anthony W. Knapp. Van Nostrand, Princeton, N. J. 1966. xi+439 pp. $14.75. A systematic monograph based on the recent research literature and dealing with the foundations as well as some topics in potential and boundary theory. "The book's theme is a discussion of relations among what might be called the descriptive quantities associated with Markov chains—probabilities of events and means of random variables that give insight into the behavior of the chains." T (17–18), S, P.

Probability, A Survey of the Mathematical Theory. By John Lamperti. Benjamin, New York, 1966. x+150 pp. $8.00 (cloth), $3.95 (paper). Based on a one-semester graduate course designed to present the main lines of probability theory up to 1950. Sums of random variables play a central role in dealing with laws of large numbers, limiting distributions, the central limit problem, and stochastic processes. One of a series of "brief topical booklets" edited by R. Gunning and H. Rossi in the hope of meeting the pedagogical problems that arise from expansion and increasingly complicated internal structure of mathematics. T (17), S, P, L.

Simultaneous Statistical Inference. By. Rupert G. Miller, Jr. McGraw-Hill, New York, 1966. xv+272 pp. $11.50. This is intended as a reference source or a textbook at the graduate level covering "simultaneous confidence intervals and multiple significance tests in all phases of statistics." T (after graduate training in statistics). S, P.

Elements of Mathematical Statistics, 2nd ed. By J. F. Ractliffe. Oxford, New York, 1967. x+224 pp. $3.00 (paper). A cook book with rather outdated content.

Exercises in Probability and Statistics for Mathematics Undergraduates. With answers and hints on solutions. By N. A. Rahman. Hafner, New York, 1967. xi+307 pp. $10.50. Over 400 problems in 140 pages under the headings of discrete probability (including simple difference equations and generating functions), continuous random variable (including joint and simple derived distributions), estimation, tests, inference (including bivariate correlation and regression), characteristic functions (including use in deriving sampling distributions). The hints on solutions (165 pages) include references to sources—a commendable feature that will help turn students toward the literature. T (15–16), S, P, L.

Stochastic Processes. Problems and Solutions. By Lajos Takacs, Translated by P. Zador. Methuen, London, 1966. xi+135 pp. $4.45 (cloth) $1.95 (paper). Brief exposition and problems with partial solutions relating to Markov chains, Markov processes, non-markovian processes. List of references. T, S, P.

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor H. L. Alder, University of California, Davis, represented the Association at the inauguration of President John Summerskill of San Francisco State College on May 2, 1967.

Professor E. G. H. Comfort, Ripon College, represented the Association at the inauguration of President B. S. Adams of Ripon College on May 6, 1967.

Professor H. M. Gehman, SUNY at Buffalo, represented the Association at the inauguration of President Martin Meyerson of SUNY at Buffalo on May 29, 1967.

Professor V. C. Harris, San Diego State College, represented the Association at the inauguration of President J. A. Greenlee of California State College on May 8, 1967.

Professor R. J. Kohlmeyer, Albright College, represented the Association at the inauguration of President M. J. Mays of Elizabethtown College on April 15, 1967.

Professor A. W. McGaughey, Bradley University, represented the Association at the inauguration of President G. L. McConagha of Blackburn College on April 22, 1967.

Professor H. M. Nahikian, North Carolina State University, represented the Association at the inauguration of President E. B. Heilman of Meredith College on April 15, 1967.

Professor C. J. Pipes, Southern Methodist University, represented the Association at the inauguration of President D. W. Halladay of East Texas State University on April 17, 1967.

Professor Haim Reingold, Illinois Institute of Technology, represented the Association at the inauguration of President R. A. Weil of Roosevelt University on April 16, 1967.

Professor Norman Schaumberger, Bronx Community College, represented the Association at the inauguration of President J. A. Colston of Bronx Community College on April 23, 1967.

Professor W. J. Thomsen, Moorhead State College, represented the Association at the inauguration of President J. F. Nickerson of Mankato State College on May 11, 1967.

Amherst College: Assistant Professor D. E. Crabtree, University of Massachusetts, has been appointed Assistant Professor; Dr. Norton Starr, Massachusetts Institute of Technology, has been appointed Assistant Professor.

Florida Presbyterian College: Dr. B. H. Maddox, Presbyterian College, and Associate Professor R. G. Van Meter, Geneva College, have been appointed Associate Professors.

SUNY at Albany: Professor Violet H. Larney is Acting Chairman of the Mathematics Department; Assistant Professor G. E. Martin, University of Rhode Island, has been appointed Assistant Professor.

Mr. J. T. Anderson, Duke University, has been appointed Instructor at Hamilton College.

Mr. J. P. Becker, Stanford University, has been appointed Assistant Professor at Rutgers— The State University.

Professor R. H. Bing, University of Wisconsin, has been appointed Chairman of the Division of Mathematical Sciences, National Research Council.

Dr. I. E. Block has been promoted to Manager of AUERBACH Corporation's Scientific Information Division.

Mr. R. G. Bowers, University of Delaware, has been appointed Assistant Professor at Williamsport Area Community College.

Dr. L. E. Bragg, University of Minnesota, has been appointed Assistant Professor at the University of Kentucky.

Mr. D. A. Breault, Sylvania Applied Research Laboratory, has been appointed Senior Analyst at the Harvard Computing Center.

Dr. C. E. Burgess has been appointed Chairman of the Department of Mathematics at the University of Utah.

Mr. Marvin H. J. Gruber, SUNY at Buffalo, has been appointed Instructor at the Rochester Institute of Technology.

Assistant Professor S. L. Gulden has been promoted to Associate Professor at Lehigh University.

Dr. A. W. Landers, Brooklyn College, has been appointed Director of the Office of Grants and Research.

Mr. E. E. Mayer, Blue Mountain Community College, has been appointed Dean of Liberal Arts and Sciences.

Mr. O. B. McCowan, Kilgore College, has been appointed Assistant Professor at Belmont College.

Dr. G. P. Patil, Pennsylvania State University, has been elected an ordinary member of the International Statistical Institute.

Professor W. M. Perel has been appointed Head of the Mathematics Department at Wichita State University.

Dr. L. V. Quintas, CUNY, has been appointed Professor at Pace College.

Professor R. A. Raimi has been appointed Associate Dean for Graduate Studies at the University of Rochester.

Mr. J. W. Ridge has been appointed Director of Research in the Office of Institutional Research, Wisconsin State University.

Assistant Professor H. C. Wiser has been promoted to Associate Professor at Washington State University.

Mr. J. N. Herrmann, Young Radiator Co., died on March 6, 1967. He was a member of the Association for ten years.

Professor Emeritus H. W. Kuhn, Ohio State University, died in November 1965. He was a Charter member of the Association.

Mr. Jacob Schwartz, Goldfinger & Schwartz, died on February 24, 1967. He was a member of the Association for eight years.

Professor C. C. Torrance, U. S. Naval Postgraduate school, died on May 2, 1967. He was a member of the Association for forty years.

UNITED STATES-INDIA EXCHANGE OF SCIENTISTS AND ENGINEERS

The Governments of India and the United States signed an agreement in February, 1967 for an exchange of scientists and engineers to promote increased communication between the scientific communities of the two countries on problems of mutual interest. The national agencies which have been assigned responsibility for administering the program are the National Science Foundation (NSF) and the Indian Council for Scientific and Industrial Research (CSIR). Visits by scientists and engineers from one country to the other shall be for periods of two weeks to several months, and the total man-days per year are limited to 800 for each country. The NSF will pay transportation costs to India for American participants and the CSIR will pay subsistence and travel costs within India. Similarly, the NSF will be host to the Indian visitors while in the United States. For further information write to: United States - India Exchange Office of International Science Activities, National Science Foundation, Washington, D. C. 20550

BERNARD FRIEDMAN MEMORIAL PRIZE

The first Bernard Friedman Memorial Prize has been awarded to Ralph Ta-Shun Cheng, who has just received the Ph.D. degree from the Department of Mechanical Engineering, Aeronautical Sciences. Dr. Cheng was nominated by Professor S.A. Berger, and was selected from among all nominees by a committee under the chairmanship of Professor T. Kato. Cheng was cited for the mathematical quality of his dissertation, "An Investigation of the Laminar Flow Around the Trailing Edge of a Flat Plate."

The prize consists of a cash award bestowed annually, and is supported by a fund donated by friends of Professor Friedman. Additional contributions are welcome; they should be made out to "The Bernard Friedman Memorial Fund" and addressed to the Chairman, Department of Mathematics, University of California, Berkeley.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

MARCH MEETING OF THE SOUTHWESTERN SECTION

The annual meeting of the Southwestern Section of the MAA was held at the University of Arizona, Tucson, on March 31-April 1, 1967. There were fifty-one persons in attendance, including twenty-nine members of the Association. Professor D. E. Myers, Chairman of the section, presided.

The banquet was held on the evening of March 31. Dr. G. S. Rogers, New Mexico State University, was the guest speaker. The title of his talk was "How to pick a campsite."

The following officers were elected: Chairman, R. J. Wisner, New Mexico State University; Vice-Chairman, A. B. Gray, Jr., Northern Arizona University.

The following papers were presented:

1. *Reducibility and extended reducibility of linear differential operators*, by M. S. Klamkin, Ford Science Laboratory.

The reducibility of a class of nth order linear differential equations is first established. This is applied to solving certain nth order differential equations. The notion of reducibility is then extended and applied to 'solving' other nth order differential equations.

2. *Synthetic methods in differential geometry*, by J. H. Butchart, Northern Arizona University.

The neatness of applying elementary geometrical considerations to certain problems of differential geometry is stressed. For instance, the definition of curvature can be applied directly at times instead of appealing to the standard formulas in rectangular and polar coordinates.

3. *Matrix number theory and Fibonacci numbers*, by D. W. Hardy, New Mexico State University.

A matrix identity is used to motivate and prove some familiar formulas involving Fibonacci numbers. It is shown that more complicated formulas can also be discovered using this matrix identity. For example, a formula is given for $F_{a+b+c+\cdots+d}$ in terms of the Fibonacci numbers F_a, $F_b, \cdots, F_d$ and F_{a-1}, $F_{b-1}, \cdots, F_{d-1}$.

4. *At least 10 primes in arithmetical progression*, by Edgar Karst, University of Arizona.

Let a be the first prime in A.P., z the last, n the number of primes in A.P., and d the common difference of the form $d=p_1^r \cdot p_2^s \cdots p_k^w$, with $p_1, p_2, p_3, \cdots$ the sequence of consecutive primes,

2, 3, 5, $\cdots$, and $r, s, t, \cdots$ positive integers >0, not necessarily distinct. Then the sequence of primes in A.P. is called complete, if $n=p_{k+1}-1$ and $|a|>|p_{k+1}|$. In all other cases the sequence is called incomplete. The only complete sequence known since 1910 is the Escott sequence 199, 409, $\cdots$, 2089 with $d=210$ and $n=10$. There are now two more of this type: 52879, 53299, $\cdots$, 56659 with $d=420$ and $n=10$, and 34913, 37013, $\cdots$, 53813 with $d=2100$ and $n=10$. The only incomplete sequences with $n>10$ known since 1963 and 1964, respectively, are the Golubev sequence 23143, 53173, $\cdots$, 353473 with $d=30030$ and $n=12$, and the Seredinskij sequence -55117, 4943, $\cdots$, 725663 with $d=60060$ and $n=14$. There are now three more with $d=30030$ and $n=11$, starting at -24023, 75307, and 820793. The new results were accomplished by a program written for the IBM 1130 by the author.

5. *A noncommutative quotient ring*, by Merry Lomanitz, New Mexico Institute of Mining Technology.

6. *Mathematical control theory applied to management science*, by G. L. Thompson, Carnegie Institute of Technology.

7. *Game theory and the von Neumann model of an expanding economy*, G. L. Thompson, Carnegie Institute of Technology.

8. *Problem solving via transforms*, by M. S. Klamkin, Ford Scientific Laboratory.

Usually transform theory is thought of in terms of certain definite integrals. Here we take a much broader viewpoint. We illustrate (with slides, some in color) the philosophy and applications of transform theory by a series of problems starting off with some simple ones in arithmetic and geometry. We then consider some problems in probability, number theory, combinatorics, differential equations and physics.

The meeting was concluded with a panel discussion of the Conference Board of the Mathematical Sciences publication *The Role of Axiomatics and Problem Solving in Mathematics*. The outcome of the discussion was the following: 1. Mathematics without applications becomes sterile. 2. Axiomatics are necessary to bring order to the study of mathematics.

S. T. Kao. *Secretary-Treasurer*

APRIL MEETING OF THE IOWA SECTION

The fifty-fourth regular meeting of the Iowa Section of the MAA was held at Drake University, Des Moines, on April 21, 1967. Chairman W. L. Waltmann presided. Total attendance was ninety-six, fifty-eight of whom were members of the Association. Routine business was considered at the afternoon session.

The following officers were elected: Chairman, C. M. Lindsay, Coe College, Cedar Rapids; Vice-Chairman, Rev. J. C. Friedell, Loras College, Dubuque; Secretary-Treasurer, B. E. Gillam, Drake University, Des Moines.

The following motion was made and duly passed: "Prof. Earle Canfield was given a standing vote of thanks for his eleven years service to the Iowa Section of MAA as its Secretary-Treasurer."

The following papers completed the program:

1. *Karl Menger's contribution to ethics*, by E. S. Allen, Iowa State University.

Karl Menger's *Moral, Wille und Weltgestaltung* (1934) is a noteworthy application of the mathematical way of thought to ethics. Refuting the possibility of a universally accepted morality, Menger concentrates on the classification of men according to their desires and the norms of conduct which they choose. The graphical and tabular analysis even of a simple three-way choice is quite complex. The will-group (Willensgruppe) consists of men sufficiently like-minded to avoid collision within the group. The author envisages, and would hope for, will-groups whose codes, though different, would not prevent mutual toleration.

2. *The reversed upper central series in the polarization process in groups*, by Donald Pilgrim, Luther College.

Let G be the group and $\{Z_n\}$ be the upper central series of G. If $Z_n=G$ for some positive integer n and if c is the least such integer, we define a chain $\{K_i\}$ of subgroups of G by: (a) $K_i=Z_{c-i+1}$ if $1\leqq i\leqq c$ and (b) $K_i=\{1\}$ if $i\geqq c+1$. Call the chain $\{K_i\}$ the reversed upper central series of G. Now suppose we are considering a class, S, of groups defined by one or more identical relations involving commutators; for example, by the fourth Engel condition $(y, x, x, x, x)=1$. An illustration is given on how the reversed upper central series may be used to determine a bound for the nilpotency class of those groups in S which are nilpotent and have given number (finite) of generators and have no elements of certain prime orders. Finally, this chain is used to obtain polarized identical relations involving commutators in groups satisfying the fourth Engel condition.

3. *Functions "close" to continuous functions*, by A. Irudayanathan, Iowa State University, introduced by the Chairman.

Definitions: (1) $f\in Y^X$ is (weakly) nearly continuous iff for every open cover α of Y, there is a continuous $g\in Y^X$ such that for every $x\in X, f(x), g(x)\in U$ for some $U\in\alpha$ (i.e., g is α-near to f). (2) $A\subset Y$ is nearly connected (nearly compact) iff for every open cover α of Y, there is a connected (compact) set $B\subset Y$ such that $A\subset\alpha^*(B)$ and $B\subset\alpha^*(A)$. $[\alpha^*(A)=\bigcup\{U\in\alpha: U\cap A\neq\phi\}]$.

RESULTS. (1) Continuity implies near continuity; converse is true if range is regular (satisfies T_3), (2) composition of continuous and nearly continuous functions is nearly continuous; composition of two nearly continuous functions is weakly nearly continuous; (3) nearly continuous images of connected (compact) sets are nearly connected (nearly compact); (4) nearly connectedness and nearly compactness are both continuous invariants.

4. *Variance estimates in nested designs*, by F. C. Leone, State University of Iowa (by invitation).

Nested designs are widely publicized and used to isolate and estimate variances with multistage processes. Beyond the two-stage design, there is little information on the distributions of the estimates of variance components. "Staggered" designs and "inverted" designs are presently employed to decrease the variance of the estimates of the true variances. These are successful at the upper stages of the design at the expense of increasing the variability at the lower stages. Some results are presented, mostly empirical, for the designs of size forty and eight combinations of variances. The frequency of occurrence of negative estimates of variance components, as well as the very strongly biased results in estimation (in the cases where $H_0:\sigma_i^2=0$ is rejected) are emphasized.

5. Panel Discussion: *Problems in the first two years of college mathematics teaching.* J. C. Friedell (Chairman), Loras College; D. Q. Porter, Muscatine Community College; T. H. Price, State University of Iowa.

The main problem at the Chairman's college is the varied background and abilities that potential mathematics and science majors bring from high school. All register for the same course as freshmen, and several weeks of pre-calculus material are given, including tests; those to begin calculus immediately are selected, based on all information available. The rest take one or two semesters of preparatory material before beginning calculus. Mr. Porter asked that larger institutions help the Junior College departments while allowing them to maintain their independence and identity. It is very helpful if the larger universities send back the grades earned by transfer students. Prof. Price agreed that counselling the transfer student about the proper courses to take is of utmost importance. Articulation concerning calculus courses is needed. Several of those attending offered suggestions about these problems in the discussion that ensued.

6. *The role of axiomatics and problem solving in mathematics*, by F. W. Lott, Jr., State College of Iowa.

The Role of Axiomatics and Problem Solving in Mathematics, published by the Conference Board of the Mathematical Sciences, was discussed together with its implications for the college mathematics program.

7. *Convergent solutions of ordinary linear homogeneous difference equations in the neighborhood of an irregular singular point*, by W. J. A. Culmer, Mid-Western College, Denison, Iowa.

This paper deals with the solution of the linear homogeneous difference equation $X(s+1) = s^h A(s)X(s)$, where s is complex, $A(s)$ and $X(s)$ are 2 by 2 matrices and $A(s)$ is representable as a power series in s^{-1} with known coefficients convergent in some neighborhood of $s = \infty$. Formal power series solutions in powers of either s^{-1} or $s^{-1/2}$ are obtained. With one exception these are shown to be asymptotic representations of true solutions in certain regions of the s-plane. The asymptotic series solutions in general diverge, nevertheless are Borel summable and replaceable by convergent factorial series.

8. *Eigenvectors by norm reduction*, by Robert Lambert and Richard Sincovec, Iowa State University, Ames.

An iterative procedure for finding the eigenvectors of a symmetric matrix is developed based on a new theorem concerning the commutativity of a simple product matrix with the given symmetric matrix. The Euclidean norm of a residual commutator matrix is iteratively reduced by a modified gradient process which changes the simple product matrix successively until the commutator is forced to zero. This will yield both eigenvectors and eigenvalues to high precision. Several examples are given which give more precise results than some other known methods.

9. *Riemann integration in ordered fields*, by J. M. H. Olmsted, Southern Illinois University, Carbondale (by invitation).

Riemann integrability in an ordered field F is defined by upper and lower step-functions. The collection I of integrable functions is a vector space; also an algebra and lattice. An integrable function may or may not possess an integral. The set D of functions possessing integrals is a vector subspace of I, but may fail to be an l algebra or lattice. If F is Archimedean, then completeness of F is equivalent to each: $D = I$; D is an algebra; D is a lattice. However, there exist non-Archimedean (hence incomplete) fields in which all three are satisfied.

B. E. GILLAM, *Secretary-Treasurer*

APRIL MEETING OF THE KANSAS SECTION

The fifty-second annual meeting of the Kansas Section of the MAA was held at Fort Hays Kansas State College, Hays, Kansas, on April 22, 1967, in conjunction with the annual meeting of the Kansas Association of Teachers of Mathematics. There were 194 persons registered including 75 members of the Section. Chairman Jimmy Rice presided at the morning and afternoon sessions.

The following officers were elected: Chairman, Sister Mary Paul Buser, Marymount College, Salina; Vice-chairman, Jeneva J. Brewer, Wichita University; Secretary-Treasurer, Lyle Dixon, Kansas State University.

The following papers were presented:

1. *The structure of mathematics in grades K-12*, by S. J. Bezuszka, Boston College.

Contemporary mathematics includes both new content and revised methods for teaching mathematics at all levels. The structure of mathematics is a unifying factor which should play an important role in the mathematics curricula of the present. In the lower grades one should stress student creativity, intuition, and recognition of patterns. In the junior high school the formal development of a mathematical system may be introduced, including: a set of elements, a set of operations, a set of definitions, a set of unproved statements (assumptions), a set of proved statements (theorems), and a system of logic. The mathematical systems of the natural, rational, and real numbers are explored in this framework. Senior high school courses may also be approached from this viewpoint.

2. *Committee evaluation report on CUPM general college curriculum in mathematics*, by Lyle Dixon, Kansas State University.

The committee appointed by the executive council of the Kansas Section of MAA reported on its evaluation of CUPM's recommendations for a general curriculum in mathematics for colleges. The Section approved the report and approved a resolution expressing its thanks to CUPM for its continued leadership.

3. *Eight numbers*, by Ellen Veed, Fort Hays Kansas State College.

If A is a positive integer, let $F(A)$ be the sum of the squares of the digits of A. Define $F^k(A) = F(F^{k-1}(A))$. Either there is a k_1 such that $F^k(A)=1$ for all $k \geqq k_1$ or there is a k_2 such that $F^k(A) \in S$ for all $k \geqq k_2$, where $S=\{4, 16, 37, 58, 89, 145, 42, 20\}$. That is, under iteration of $F(A)$ all positive integers are divided into two classes, one with the 1-cycle $1\rightarrow 1$, and the other with the 8-cycle $4\rightarrow 16\rightarrow 37\rightarrow 58\rightarrow 89\rightarrow 145\rightarrow 42\rightarrow 20\rightarrow 4$.

4. *Topics from integral geometry in elliptic spaces*, by A. H. Simonson, Kansas State University.

The "measures" of linear subspaces for elliptic 2-space and 3-space were derived using information available from the hemisphere model of the single pole elliptic plane.

5. *Singular perturbations of the Dirichlet problem with homogeneous boundary data*, by W. M. Greenlee, University of Kansas.

A singular perturbation problem is a problem consisting of a differential equation involving a small parameter ϵ in which the order of the equation is smaller for $\epsilon=0$ than for $\epsilon\neq 0$. One wants to analyze the behavior of solutions, eigenvalues, etc. as $\epsilon\rightarrow 0$. The paper gives a rate of convergence result for solutions of the (generalized) Dirichlet problem with homogeneous boundary conditions. The result refines some work of Huet, Ann. Inst. Fourier Grenoble (1960).

HELEN KRIEGSMAN, *Secretary-Treasurer*

APRIL MEETING OF THE KENTUCKY SECTION

The fiftieth annual meeting of the Kentucky Section of the MAA was held at Murray State University, Murray, on April 1, 1967. A total of eighty-two persons attended the meeting, of whom fifty-five were members of the Association.

At the business meeting, the following members were elected: Chairman: W. C. Royster, University of Kentucky; Secretary-Treasurer: Henry Spragens, University of Louisville; High School Testing Program: Stephen Puckette, University of Kentucky.

Various items were discussed and acted upon and L. L. Scott reported on the MAA 1967 high school mathematics contest in Kentucky.

The following papers were presented:

1. *Some remarks on interpolation in the Hardy H^p spaces*, by J. H. Wells, University of Kentucky.

2. *Nonembeddable topological semigroups*, by J. W. Stepp, Eastern Kentucky University.

DEFINITION. A topological semigroup S is said to have property P if (1) S contains an open dense topological group G and (2) for every net $\{g_i\}_{i\in A} g \in G$, such that $\{g_i\}_{i\in A}$ does not have a cluster point in X, then $\{g_i^{-1}\}_{i\in A}$ has a cluster point in S. Several examples of topological semigroups with property P are given and the following theorem is discussed: *If S is a topological semigroup with property P then there does not exist a topological semigroup with S as a proper dense subsemigroup.*

3. *Peano spaces*, by Musa Shubbak, Murray State University.

4. *Remarks on a problem in musical composition*, by W. H. Spragens, University of Louisville.

5. *The "new math" and computerized arithmetic*, by A. C. R. Newbery, University of Kentucky.

Virtually all of the arithmetic that is performed today is executed on digital computers. In computerized arithmetic the distributive, associative and cancellation laws do not hold. The

speaker discusses some of the anomalies which arise from this, and he questions whether the "new math" provides an adequate basis for the understanding of computerized arithmetic.

6. *Numerical evaluation of improper integrals*, by R. H. Geeslin, University of Louisville.

The method of repeated interval halving is adapted to obtain the direct evaluation of integrals over infinite intervals and integrals of unbounded functions over finite intervals. The method is quite general and can be applied to any convergent integral. Several parameters provide for adjusting the accuracy and time of the computation. Without any appreciable increase in computing time, the Newton-Cotes formula for five points gave better accuracy than the trapezoid rule, and Simpson's Rule was least accurate and slowest for the functions integrated. Fortran programs are available on request.

7. *An ordered sample*, by J. C. Eaves, University of Kentucky.

Probability density functions are obtained for special character samples selected from a sequentially independent random sample of order 3.

8. *Vector lattices*, by J. M. H. Olmsted, Southern Illinois University, (invited address).

The concepts of vector space, lattice, and vector lattice, in both concrete and abstract form, were presented, with several illustrative examples and counterexamples chosen from familiar vector spaces of functions and polynomials. These examples serve to illustrate an important structural distinction between an algebraic polynomial and a polynomial function, as well as to clarify the idea of a sublattice. Finally, a single specific pair of mathematical objects was exhibited and examined from several points of view, depending on the vector lattice in which they are embedded.

9. *Problems of choice*, by Stephen Puckette, University of Kentucky.

Defects of election methods in several states are discussed as instances of Arrow's theorem and the possibility of weakening the assumption of independence from irrelevant alternatives.

J. C. EAVES, *Secretary-Treasurer*

MAY MEETING OF THE ALLEGHENY MOUNTAIN SECTION

The forty-first meeting of the Allegheny Mountain Section was held on May 6, 1967, at West Virginia University, Morgantown, with 166 people present including 114 members.

The Chairman of the Section, F. E. Justis, Geneva College, introduced Dr. H. B. Heflin, Acting President of the University, for welcoming remarks and Professor H. W. Gould, who reviewed the first century of mathematics and astronomy at West Virginia University in interesting detail.

Professor Mario Benedicty, University of Pittsburgh, gave an invited address titled *Singularities of algebraic varieties*. Professor Paulo Ribenboim, Queens College, Kingston, Ontario, gave an excellent presentation of *p-adic numbers*.

A panel of members discussed the 1965 CUPM curriculum proposals and suggested the following resolution which was voted on and passed by the Section in the business meeting: The Allegheny Mountain Section of MAA expresses its approval of the scope and general content of the 1965 CUPM report, *A General Curriculum in Mathematics for Colleges*. With certain exceptions the courses outlined therein appear to be both highly desirable and within the ultimate capabilities of most of the colleges represented here. Therefore it is resolved that the individual members of the Section should take whatever steps are feasible to bring their programs in line with the general content of this report. The Curriculum panelists, ably moderated by Craig Comstock, Penn State University, were: I. D. Peters and Franz Hiergeist, West Virginia University, Ward Bouwsma and Allan Krall, Penn State University, Frank Perry, Washington and Jefferson College, George Novak, California State College, Anthony Pagano, Slippery Rock State College, and C. F. Sebesta, Duquesne University.

In the business meeting, reports of the annual High School Mathematics Contest were given by I. D. Peters for West Virginia and Frank Perry for Western Pennsylvania.

Warm commendations for their work were voiced; Frank Perry's resignation was accepted with regret.

The winning team for the Section in the William Lowell Putnam Competition was coached by C. V. Coffman, Carnegie Institute of Technology, who received gift memberships in MAA for the three team members: Timothy Eaton, Robert Moll and David Wise.

I. D. Peters proposed the following resolution: Resolved that the Allegheny Mountain Section through the secretary extend in writing to the members of Cabell County, W. Va. an invitation to join the Allegheny Mountain Section and that a copy of the invitation be sent to the MAA Executive Director, Professor H. M. Gehman. The resolution was passed.

James Bartoo, Penn State University, chairman of the nominating committee including I. D. Peters and P. N. Carpenter, presented a slate of officers who were unanimously elected for two years: Chairman, H. L. Krall, Penn State University; Secretary-Treasurer, W. A. Hallam, West Virginia University; Member of Executive Committee, F. E. Justis, Geneva College.

The following ten-minute papers were given:

1. *Mathematics and astronomy at West Virginia University—the first century*, by H. W. Gould, West Virginia University.

The first significant mathematician at West Virginia University after its founding in 1867 was the Norwegian geometer John Arndt Eiesland (1867–1950), who headed the Department from 1907 till 1938. He published extensively and directed the first doctorates granted at the University. His personal library laid the cornerstone for a strong research library, and his name became a legend in Morgantown. The next most important mathematician at West Virginia was Clarence Newton Reynolds, Jr. (1890–1954), whose work on the four color conjecture brought him international fame in 1926–27 when he showed that an irreducible map must have at least 28 countries, thereby improving on a result of Franklin.

The work of Robert Maurice Mathews, who was an active problem solver in various journals prior to his death in 1929, was also discussed.

Astronomy at West Virginia traces back to 1872 when a telescope was procured; parts of this are still in existence. An observatory of some distinction existed in Morgantown from 1900 until about 1930. Strengths and weaknesses of the first century offer suggestions for future progress.

2. *The Doctor of Arts in mathematics at Carnegie*, by R. A. Moore, Carnegie Institute of Technology.

Beginning as early as June 1967, Carnegie Institute of Technology, (by that time, Carnegie-Mellon University) will grant the degree of Doctor of Arts in Mathematics. In its essentials, the degree program consists of three years of full-time study in mathematics and a fourth year as an intern in the teaching of mathematics. The course work at the graduate level in mathematics will amount to about 15 semester courses which is substantially equal to that of an average Ph.D. candidate. The dissertation, unlike the Ph.D. dissertation, will be expository in nature but, hopefully, of some scholarly merit. As a part of his training the candidate will not only teach in the Department, as all present Ph.D. candidates do, but he will also participate in the curriculum and course planning. In a way, the ideal candidate for this degree is a bright and energetic student who struggles against nature and instinct for six years, or so, to finally produce an acceptable but undistinguished Ph.D. thesis and then goes his way to a productive career in college teaching. Our objective is to systemize and shorten the path to a career of college teaching for the student who does not, and will never, make a significant contribution to mathematical research.

3. *Invariant definitions for vector calculus*, by Oswald Wyler, Carnegie Institute of Technology.

Coordinate-free definitions of gradient, divergence, and rotation are given, at the level of abstraction of an advanced calculus course.

4. *On a certain approximation theorem*, by S. Mrowka, Pennsylvania State University.

Let F be a real-valued function on a set X, and let a be a real number. A set having one of the following forms: $L_a(f)=\{p\in X: f(p)\leqq a\}$ or $L^a(f)=\{p\in X: f(p)\geqq a\}$ will be called a Lebesgue set of f. The following theorem holds: *Let F be a class a real-valued functions on X such that* (a) F *contains all constant functions on* X; (b) $f, g\in F$ *implies* $f+g\in F$ *and* $f\cdot g\in F$; (c) $f\in F$ *and* $f(p)\neq 0$ *for every* $p\in X$ *implies* $f\in F$; (d) *if* $f_n\in F$ *for* $n=1, 2, \cdots$ and $f_n\to f$ *uniformly on* X, *then* $f\in F$. *Let f_0 be an arbitrary function on X. The following conditions are equivalent:*

1. $f_0\in F$; 2. *every Lebesgue set of* f_0 *is a Lebesgue set of some functions in* F; 3. *for every* a, b, $a<b$, *there are* $g_1, g_2\in F$ *such that* $g_1[L_a(f_0)]\cap g_1[L^b(f_0)]=g_2[L_a(f_0)]\cap g_2[L^b(f_0)]=\varnothing$. The above theorem appears, under somewhat different formulation, in S. Mrowka, Notices AMS, October 1964, p. 666. It was given there for topological purposes. It turns out that this theorem can be used to simplify proofs of various classical theorems in the theory of functions of real variable.

5. *Orthogonal polynomials in two variables*, by H. L. Krall and I. M. Sheffer, Pennsylvania State University, read by Mr. Krall.

The classical polynomials of Jacobi, Laguerre and Hermite satisfy a differential equation of the type $(ax^2+bx+c)y_m''+(dx+e)y_m'=\lambda_m y_m$. In this paper we are interested in orthogonal polynomial solutions of a partial differential equation of the type $(a_1x^2+b_1xy+c_1y^2+d_1x+e_1y+f_1)w_{xx}+\cdots+(\cdots+f_3)w_{yy}+(g_1x+h_1y+k_1)w_x+\cdots=\lambda_m w$ where λ_m depends on the degree of the polynomial solution.

There exist (1) the solutions $\{L_k(x)L_{m-k}(y)\}$, $\{L_k(x)H_{m-k}(y)\}$, $\{H_k(x)H_{m-k}(y)\}$, where $L_m(x)$, $H_m(x)$ represent the Laguerre and Hermite polynomials; (2) the circle polynomials, with the weight function $\rho(x, y)=(1-x^2-y^2)^\alpha$ on $x^2+y^2\leqq 1$; (3) the triangle polynomials corresponding to $\rho(x, y)=x^\alpha y^\beta(1-x-y)^\gamma$ inside the triangle bounded by $x=0$, $y=0$, $x+y=1$; (4) four other classes of polynomials. Classes (2) and (3) have been studied by Hermite, Didou, Appel, Kampé de Fériet but the classes (4) are new. This listing contains all the orthogonal polynomials satisfying a differential equation of the above type, to within linear transformations of the independent variables.

6. *On classes of maximum numbers of symmetric equations in n reciprocals*, by J. L. Klemm, Indiana University of Pennsylvania.

This paper extends the work of H. A. Simmons on maximum numbers associated with symmetric equations in n reciprocals having positive coefficients to include a term $L_{s+1}\sum_{k=1}^{m}(x_1\cdots x_n)^{-k}$, including the limiting case, $m=+\infty$; consolidates the two equations considered by Simmons into a single treatment; and gives necessary and sufficient conditions, in terms of the coefficients, for the solution giving the maximum numbers to be obtained by the Kellogg process.

7. *Finding equivalent number pairs geometrically under addition, subtraction, multiplication and division*, by E. W. Bailey, Indiana University of Pennsylvania.

8. *On invariants of projective linear groups*, by J. H. Biggs, Pennsylvania State University.

In order to obtain the automorphisms of the projective linear groups over a skew field K, the connection between certain projective transformations and their eigenspaces is usually exploited. The linear transformations which represent two commuting projective transformations may anti-commute, inducing mappings which make standard invariants useless. A method is introduced which removes this difficulty. The new invariants have the same numerical connection as the standard invariants with the number of eigenspaces in a direct sum decomposition of the underlying vector space. One application is in obtaining the automorphisms of $PU_n^+K, f)$.

9. *The elimination method of solving a matrix sequencing problem*, by G. R. Hagan, I.B.M.

The traveling salesman problem is that of finding a permutation $P=(1i_2i_3\cdots i_n)$ of the integers 1 through n that minimizes the quantity $A_{1i_2}+A_{i_2i_3}+\cdots A_{i_n1}$, where A_{mn} are a given set of real numbers. The problem derives its name from the fact that a salesman wishing to travel by the shortest total distance from his home to each of $n-1$ cities, and then return home, could calculate every permutation if he were given the distances between each pair of cities on his tour.

This is closely related to the personnel-assignment problem, differing only in that P may be non-cyclic, that is, it is not necessary to return to the starting point. Most generally, this is the problem of assigning N men optimally to N different jobs. The personnel-assignment problem is mathematically equivalent to the transportation problem and both of these are special applications of the distribution problem which in turn is a special case of the linear-programming problem, i.e., the finding of a non-negative solution for a system of linear algebraic equations.

This paper gives a method of solving the traveling salesman problem—that is, a method for finding a non-cyclic solution to the personnel-assignment problem and a near-minimum permutation for non-symmetric matrices. Under these conditions (a near minimum non-cyclic solution is acceptable) this method is most useful, and in fact, appears to be stronger with larger matrices. This is a distinct advantage over the linear-programming approach.

10. *Some remarks on the Jordan canonical form*, by C. G. Cullen, University of Pittsburgh.

Let $J_m(\lambda)$ be the m by m simple Jordan matrix whose characteristic and minimum polynomials are $(x-\lambda)^m$. Let A be any n by n complex matrix, J its Jordan canonical form, and λ one of its characteristic values. Simple formulas are developed which provide the number, and the sizes, of the simple Jordan blocks of the form $J_m(\lambda)$, $m=1, 2, \cdots$, which appear in J.

BERTHA W. MATHER, *Secretary*

MAY MEETING OF THE ILLINOIS SECTION

The forty-sixth annual meeting of the Illinois Section of the MAA was held at the University of Illinois, Urbana, on May 12 and 13, 1967. Wayne McGaughey, Section Chairman, presided at the Friday afternoon session, business meeting, dinner meeting Friday evening, and the Saturday morning session. The highlight of the meeting was an invited address by Edwin Moise of Harvard University. An estimated 200 persons attended this lecture; a number of those attending this lecture, however, were students at the University of Illinois and not members of the Section. An estimated 135 members of the Association attended one or more of the various sessions.

The following officers were elected: Chairman, R.D. Boswell, Monmouth College; Vice-Chairman, Arnold Wendt, Western Illinois University; Secretary-Treasurer, Howard Saar, Western Illinois University.

The Section Governor, J. M. H. Olmsted of Southern Illinois University, reported on some of the highlights of the Meeting of the Board of Governors of the MAA at the winter meeting in Houston on January 25, 1967. The waiting period between submission of a paper and its publication in the MONTHLY is now 18 months.

Douglas Bey, chairman of the Secondary School Lecturer Committee, reported that of the 200 lecturers subsidized by the State Academy of Science under its NSF grant 30 were in mathematics. This compares to 17 out of 100 for last year. In any event, the program has been terminated by NSF; and if it is to be continued, it must be completely a section activity. The section took no action regarding continuation of the program either on a subsidized or nonsubsidized basis.

James Beach, chairman of the Membership Committee, reported that every junior college in the state had been sent a special invitation to the Section meeting.

Walter McCurdy, chairman of the Contest Committee, reported another highly successful year for this activity. Over 22,000 students from 318 schools participated. After including as an expense a $200 donation to the National MAA Contest Committee, the contest still showed a profit of about $424.

Franz Hohn, chairman of the Undergraduate Participation Committee, reported on the results of the Putnam Competition so far as Illinois students are concerned. The section will award cash prizes and/or MAA memberships to the top 15 Illinois contestants and voted to appropriate $200 to continue this activity next year.

Arnold Wendt, chairman of the Committee on the Strengthening of the Teaching of

Mathematics reported attending three meetings during the past year dealing with the pre-service and in-service training in mathematics of elementary teachers. An apparent lack of consensus at these meetings as to just what CUPM recommendations concerning this type of training meant lead CSTM to sponsor a resolution formalizing the creation of an ad hoc Section committee called the Commission on the Mathematical Preparation of Teachers of Elementary School Mathematics (CMPTESM), which is directed to consider in depth and in detail the question, "What mathematical background is necessary for the fully qualified teacher of mathematics in the elementary school?" The Section approved the resolution and appropriated $200 to support activities of the Commission, which will be chaired by Irwin Feinstein of the Circle Campus of the University of Illinois.

R. D. Boswell, chairman of the section's Study Committee for CUPM Recommendations on the Undergraduate Program, reported that the committee recommends the Illinois Section sponsor a two-day conference during the fall of 1967 devoted to a consideration of the CUPM recommendations on "Preparation for Graduate Study in Mathematics", "A General Curriculum in Mathematics for Colleges," and "Pregraduate Preparation of Research Mathematicians." The recommendation was approved by the Section.

The banquet address was given by Prof. Joseph Landin, University of Illinois Chicago Circle Campus, who spoke on *Current Developments of Higher Education in Illinois: Their Effects Upon Collegiate Mathematics.*

After a cordial welcome from Dean R. W. Rogers of the College of Liberal Arts, the following program was presented at the Friday afternoon session, dinner meeting, and the Saturday morning session.

1. *An inequality for the derivative of nonnegative polynomials*, by Michael Skalsky, Southern Illinois University.

Using a representation of nonnegative polynomials in terms of orthonormal polynomials, the following result has been obtained. If for $x \geqq 0$, $p_n(x) \geqq 0$, then $-[n/2]\int_0^\infty P_n(x)e^{-x}dx \leqq \int_0^\infty P_n'(x)e^{-x}dx \leqq \int_0^\infty P_n(x)e^{-x}dx$, where n is the degree of $P_n(x)$. In addition, the necessary and sufficient conditions are given under which the equality on the left or on the right can be obtained.

2. *Hyplanes of order* (n, m), by Subhash Saxena, Northern Illinois University.

A hyplane of order (n, m) (n and m being positive integers) is defined in terms of the following postulates. P.1: Two distinct points determine a unique line. P.2: There are exactly n points on a line ($n>1$). P.3: There are exactly $(n+m)$ lines through a point ($m>1$). P.4: There exists at least one point. It can be easily shown that a necessary condition for the existence of a hyplane is that $m(m-1)$ is a multiple of n. It so happens that this condition is also sufficient for $n=2$, and for $n=3$. For $n>3$ it may not be sufficient. It is proved that if $(n-1)=p^k$ (p being prime) and $m=(n-1)^2$, then there exists a hyplane of order (n, m); and so is true for $n=p^k$ and $m=n^2+1$.

3. *Functional analysis proofs of two theorems on analytic functions*, by L. A. Rubel, University of Illinois.

Methods of functional analysis are used to prove two basis theorems about functions of a complex variable. The first is Runge's theorem on approximation by rational functions. The second is that there exists an analytic function on an arbitrary region that interpolates any sequence of values on any discrete sequence of points. The proofs use the Hahn-Banach theorem and the Banach-Dieudonné theorem, and depend on a known characterization of the dual space of the space of analytic functions on a region, in the topology of uniform convergence on compact subsets.

4. *How to tell that a simple overhead knot is really knotted*, by E. E. Moise, Harvard University (by invitation).

It is shown that the trefoil knot does not have the knot-type of the circle. The main steps are as follows: (1) The fundamental group of the complement of a trivial knot is infinite cyclic (and

hence commutative). (2) Equivalent knots have homeomorphic complements, and therefore the fundamental groups of their complements are isomorphic. (3) Let G be the fundamental group of the complement of the trefoil. Then there is a homomorphism of G onto the symmetric group on three symbols. Therefore, (4), G is not commutative, and (5), the trefoil is not equivalent to a trivial knot.

The proof of (3) is by methods due to Artin and Fox. The rest of the methods and ideas are standard.

5. *The solution of Boolean equations*, by Helen Skala, Illinois Institute of Technology.

The ring properties of a Boolean algebra may be exploited with great advantage in the theory of Boolean equations. For, in absence of cancellation laws for union and intersection, the cancellation law for addition (symmetric difference) becomes highly significant in simplifying and solving Boolean equations. The general solution to an arbitrary Boolean equation in n unknowns may thus be obtained in a very easy manner.

6. *Recent developments in the theory of numbers*, by P. T. Bateman, University of Illinois (by invitation).

7. Panel Discussion: The Present and Future Freshman-Sophomore Program in Mathematics in the Junior and Senior Colleges.

Panel: W. A. Ferguson, University of Illinois (Chairman of Panel); J. M. H. Olmsted, Southern Illinois University; Franz Hohn, University of Illinois; Rupert Boswell, Monmouth College; Howard Saar, Western Illinois University.

ARNOLD WENDT, *Secretary-Treasurer*

MAY MEETING OF THE INDIANA SECTION

Eighty persons attended the May meeting of the Indiana Section of the MAA, held at Wabash College, Crawfordsville, on May 13.

Dr. Paul W. Cook, Jr., President of Wabash College, welcomed the group on behalf of his institution, and Professor Paul Mielke presided.

New officers were elected at the business meeting as follows: Kenneth Sidebottom, Indiana Central College, Chairman; Billy Rhoades, Indiana University, Vice-Chairman; Maynard Mansfield, Purdue University, Fort Wayne, Secretary-Treasurer.

The program consisted of the following three hour addresses:

1. *CUPM and the future*, by R. H. McDowell, Washington University, St. Louis.

2. *Some method in the four color problem*, by Oystein Ore, Yale University.

3. *Scales of differentiability*, by C. J. Neugebauer, Purdue University.

GEORGE PEDRICK, *Secretary-Treasurer*

MAY MEETING OF THE NEBRASKA SECTION

The forty-third annual meeting of the Nebraska Section of the MAA was held on May 6, 1967, at the University of South Dakota, Vermillion. Professor C. H. Frick, Chairman of the Section, presided. There were 72 persons in attendance of whom 45 were members of the Association. Professor E. Moise, President of the Association, gave a lecture during the morning session.

The following officers were elected for 1967–1968: Chairman, A. W. Zechmann, University of Nebraska; Vice-Chairman, W. E. Ekman, University of South Dakota; Secretary-Treasurer, H. M. Cox, University of Nebraska. Professor J. M. Earl of the University of Omaha was continued as Chairman of the Mathematics Contest Committee. Representatives of the Nebraska Section of the Mathematical Association of America, of the Nebraska Section of the National Council of Teachers of Mathematics, of the Ne-

braska Actuaries Club, and of the Nebraska Academy of sciences are on the Contest Committee.

The following papers were presented:

1. *The Nebraska-South Dakota Mathematics Contest*, by J. M. Earl, University of Omaha, and H. M. Cox, University of Nebraska.

Some 5752 contest papers from 179 Nebraska and 23 South Dakota high schools were scored and reports printed by use of IBM 1230, IBM 534, and IBM 360 machines. The median team score was 48 as compared with 59 in the 1966 Contest. Copies of the report are available upon request.

2. *Periodic solutions of second order nonlinear differential equations*, by Klaus Schmitt, University of Nebraska and Nebraska Wesleyan University.

We consider the second order ordinary differential equation (A) $x''=f(x, x', t)$, where f is assumed to be continuous on its domain of definition. If f satisfies a certain growth condition (Nagumo condition) in x', we deduce the existence of a periodic solution of (A) from the existence of "approximately" periodic solutions of both types of differential inequalities. This result is generalized and examples are given to illustrate the application of our results.

3. *One theorem on mappings of irreducibly connected spaces*, by G. L. Pfeifer, University of Nebraska.

A connected topological space X is said to be irreducibly connected about a subset A of X if there does not exist a proper subspace of X which is connected and contains A. THEOREM. If X is irreducibly connected about A and f on X onto Y is a continuous, open, closed function, and $f^{-1}f(a)$ is connected for one $a\in A$, then Y is irreducibly connected about $f(A)$.

4. *Differentiation with respect to a function*, by H. L. Hunzeker, University of Omaha.

Define the derivative of a function f with respect to a differentiator function g by $D_g f(x) = \lim_{t\to 0} 1/t[f[x+tg(x)]-f(x)]$ whenever the limit exists. The usual derivative and differential of f are obtained as special cases when 1 and Δx are the respective differentiator functions; generalizations to vector-valued functions of vector arguments follow.

5. *How to tell that a simple over-hand knot is really knotted*, by E. E. Moise, Harvard University (invited lecture).

6. *On rings with few zero divisors*, by M. D. Larsen, University of Nebraska.

Let R be a commutative ring with unity element. An ideal A of R is said to be regular if A contains at least one nonzero divisor. An ideal is said to be a 0-ideal if it consists entirely of zero divisors. A maximal 0-ideal is a maximal element in the set of 0-ideals. R is said to have few zero divisors if R has finitely-many maximal 0-ideals. [E. D. Davis, Trans. Amer. Math. Soc., 110 (1964) 196–212.] Let R be a ring with few zero divisors. Then (1) every regular ideal of R is generated by nonzero divisors and (2) if U, V are overrings of R such that the nonzero divisors of U are contained in V, then $U\subset V$. R is a quasi-valuation ring if for each pair of nonzero divisors of R, one divides the other. R is a P-ring if every overring of R is integrally closed. R is a D-ring if R is a Noetherian P-ring. Quasi-valuation ring, P-ring, and D-ring are natural generalizations of valuation ring, Prüfer domain, and Dedekind domain, respectively, to rings which allow zero divisors.

7. *Mathematics in a Korean university*, by M. M. Hasse, University of South Dakota.

A report on a year spent in Seoul National University as a Fulbright Professor.

8. *The integral of p from $-T$ to T and the differential equation $x''+px=0$*, by S. B. Eliason, University of Nebraska.

DEFINITION: $p(t)$ is said to be admissible on a closed finite interval provided there exists an associate solution $x(t)$ of $x''+p(t)=0$ with $x=0$ at the end points and positive throughout the open interval.

DEFINITION. $p(t)$ is said to be left balanced on $[-T, T]$ provided $p(t)\leqq p(-t)$ for $0\leqq t\leqq T$ with strict inequality for $0<t<d$ for some d, $0<d<T$.

From these definitions a theorem is discussed concerning the integrals of p_1 and p_2 from $-T$ to T, where p_1 and p_2 are admissible and left balanced.

9. *A terminal value problems*, by W. E. Shreve, University of Nebraska.

The Terminal Value Problem (λ) is defined as follows: (1) $y''=f(x, y, \lambda)$, $\lim_{x\to\infty} y(x)=\lambda$. y is said to be a solution to TVP (λ) if it satisfies (1) and if $y\in C^2[a, \infty)$. It is shown that if z is a solution to TVP (ν) and $\lambda\leq\nu$ then under certain conditions there exists a solution to TVP (λ).

10. *Adams-Cowell integration of oscillatory systems*, by J. F. Fox and D. D. Gibbs, University of South Dakota; introduced by W. E. Ekman.

High backward differences are computed from a few data points so as to enable the Adams and Cowell integrations to take advantage of the natural frequency of the function.

11. *Axiomatics and problem solving*, by Richard La Rue, University of South Dakota.

H. M. Cox, *Secretary-Treasurer*

MAY MEETING OF THE NEW JERSEY SECTION

The second joint meeting of the New Jersey Section of the Mathematical Association of America and the Association of Mathematics Teachers of New Jersey was held at Ocean County College on May 6, 1967. Dean A. E. Meder, Jr., Chairman of the Section, presided at the morning session and F. A. Brooks, Jr., Program Chairman, presided at the afternoon session. One hundred and thirty persons attended the meeting, including forty-five members of MAA.

There was no business meeting.

The morning session was as follows:

1. *Computer assisted instruction in modern mathematics*, by C. A. Riedesel, Penn. State University (introduced by A. E. Meder, Jr.).

2. *Advanced placement program in mathematics—present and future*, by Marion G. Epstein, ETS, Princeton, N. J. (by invitation).

The following paper was presented at the afternoon session:

The Programmed High School—A look at the future, by J. M. Honeycutt, American Cyanamid, Wayne, N. J. (introduced by F. A. Brooks, Jr.).

F. A. VARRICHIO, *Secretary*

MAY MEETING OF THE UPPER NEW YORK STATE SECTION

The annual meeting of the Upper New York State Section of the MAA was held at the State University College at Plattsburgh, New York, on Saturday, May 20, 1967. R. D. Larsson, Chairman of the section, presided at the morning session, and D. W. Hall, Vice-Chairman, presided at the afternoon session. There were 103 persons in attendance, including 88 members of the Association.

At the business meeting the following officers were elected: Chairman, D. W. Hall SUNY at Binghamton; Vice-Chairman, F. R. Olson, SUNY College at Fredonia; Secretary-Treasurer, Mary Williams, Skidmore College. Nura Turner reported on the 1967 MAA High School Mathematics Contest, and brought to the Section an invitation from Mr. Maurice Goldsmith, Chairman, Advisory Committee, Guiness Awards Ceremony, to bring a team of secondary school students from the N. Y. Upstate Contest Section to London in 1968 to compete in mathematics against a similar British team. The Section authorized the Contest Committee to accept the invitation, subject to the successful working out of the many problems such a meet would involve. R. D. Larsson reported that response to the Undergraduate Paper Contest was disappointing. Nevertheless, the

Section voted to continue the contest for another year. J. M. Perry, Chairman of the Committee to study the CUPM report, *General Curriculum in Mathematics for Colleges*, presented the findings of his committee, which, in general, were quite complimentary to the GCMC report. The Section voted to accept his report for transmittal to CUPM.

The program was as follows:

1. *Panel discussion: a general curriculum in mathematics for colleges—a critique of the CUPM recommendations*, by J. M. Perry, Wells College (moderator), and J. S. Klein, Hobart College; Violet H. Larney, SUNY at Albany; F. D. Parker, St. Lawrence University; F. S. Hawthorne, N. Y. State Education Department; P. W. Gilbert, Syracuse University (panelists).

2. *On the solution to Cantor's Problem*, by Andrey Feuerverger, McGill University, Undergraduate Paper Contest winner.

Sufficient background was given to make possible a rigorous statement of Cantor's Continuum Hypothesis. After a brief statement of the results of Gödel (1940) and Cohen (1963) regarding this problem, the basic structure of the simplified proof by Scott (1966) was outlined.

3. *How to tell that a simple overhand knot is really knotted*, by E. E. Moise, Harvard University, President of MAA.

4. *Dimension Theory*, by D. W. Henderson, Cornell University.

Two questions were presented from the dimension theory of infinite dimensional spaces. The first question asked for which spaces are the large (Ind) and the small (ind) transfinite inductive dimensions equivalent. The second question asked which infinite dimensional spaces have subsets of each finite dimension.

5. *Naming the irreducible representations of the symmetric group*, by A. J. Coleman, Queen's University.

Young diagrams, standard Young tableaux, Young's orthogonal irreducible representations, and a simple method of obtaining the dimension of a representation of S_N, as $N!$ divided by the content of the hook-graph, were explained by means of examples. (A more extensive account of this material will appear in Volume 4 of Advances in Quantum Chemistry, Academic Press, under the title "The Symmetric Group Made Easy.")

6. *Duo rings and a theorem of Jacobson*, by H. E. Bell, Union College.

A well-known proof of the Jacobson "$x^{n(x)}=x$ theorem" avoids structure theory arguments by establishing that the rings involved are duo rings—rings in which every one-sided ideal is two-sided. The same device is used to provide an elementary proof of Herstein's "$(xy-yx)^n=(xy-yx)$ theorem"; and an investigation of completely prime ideals in duo rings yields the result that a regular duo ring is commutative if it possesses a property which implies commutativity in division rings, and is preserved by homomorphisms.

7. *Recent CUPM proposals in mathematics for engineers*, by R. J. Walker, Cornell University.

Recommendations on the Undergraduate Mathematics Program for Engineers and Physicists, published by CUPM in 1962, has been revised. The changes are few, the most striking are being a greatly increased emphasis on automatic computing.

A five year program in applied mathematics, called "Mathematical Engineering," is presented for the consideration of Departments of Mathematics and Engineering. It combines a heavy central core of mathematics and physical science with any of a number of engineering specialties. The graduate of such a program should be able to make powerful applications of mathematics to many different fields.

N. G. GUNDERSON, *Secretary-Treasurer*

CALENDAR OF FUTURE MEETINGS

Fifty-first Annual Meeting, San Francisco Hilton, California, January 25–27, 1968.

Forty-ninth Summer Meeting, University of Wisconsin, Madison, Wisconsin, August 26–28, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, Indiana University of Pennsylvania, Indiana, April 27, 1968.

FLORIDA

ILLINOIS, Southern Illinois University, Edwardsville Campus, May 10–11, 1968.

INDIANA, Marian College, Indianapolis, November 11, 1967.

IOWA, Wartburg College, Waverly, April 19, 1968.

KANSAS, Marymount College, Salina, Spring 1968.

KENTUCKY, University of Kentucky, Lexington, Spring 1968.

LOUISIANA-MISSISSIPPI, Broadwater Beach Hotel, Biloxi, Mississippi, February 16–17, 1968.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA, Morgan State College, Baltimore, December 9, 1967.

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA, South Dakota State University, Brookings, November 11, 1967.

MISSOURI, Lindenwood College, St. Charles, April 27, 1968.

NEBRASKA, Nebraska Center for Continuing Education, Lincoln, April 26–27, 1968.

NEW JERSEY, St. Peter's College, Jersey City, November 4, 1967.

NORTHEASTERN, Phillips Academy, Andover, Mass., November 25, 1967.

NORTHERN CALIFORNIA

OHIO

OKLAHOMA-ARKANSAS, Federal Aviation Agency, Oklahoma City, March 29–30, 1968.

PACIFIC NORTHWEST, Reed College, Portland, Oregon, June 14–15, 1968.

PHILADELPHIA, University of Delaware, Newark, November 18, 1967.

ROCKY MOUNTAIN, University of Denver, Colorado, May 10–11, 1968.

SOUTHEASTERN, East Carolina College, Greenville, North Carolina, March 29–30, 1968.

SOUTHERN CALIFORNIA, Loyola University of Los Angeles, Los Angeles, March 9, 1968.

SOUTHWESTERN, New Mexico State University, University Park, Spring 1968.

TEXAS, Texas A and M University, College Station, April 19–20, 1968.

UPPER NEW YORK STATE, State University College at Buffalo, November 4, 1967.

WISCONSIN, Wisconsin State University, La Crosse, May 4, 1968.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, New York, December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, San Francisco Hilton, January 23–26, 1968.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, University of California, Los Angeles, June 17–20, 1968.

ASSOCIATION FOR COMPUTING MACHINERY, New York Hilton, November 10, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC, Sheraton-Boston Hotel, December 27–28, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Hall, Philadelphia, Pennsylvania, April 17–20, 1968.

OPERATIONS RESEARCH SOCIETY OF AMERICA, Sheraton-Chicago Hotel, November 1–3, 1967.

PI MU EPSILON

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, University of California at Santa Barbara, November 29–30, December 1–2, 1967. (Symposium on combinatorial mathematics.)

from Cambridge

A Mathematician's Apology
G. H. HARDY — **Foreword by C. P. SNOW**

Here is a classic by a distinguished mathematician, just reissued with a new foreword by C. P. Snow who applies his gifts as a novelist to his memories of a man he greatly admired.

Hardy's "Apology" is a personal account of what mathematics meant to him as a man. Writing with integrity and good humor, he discusses and illustrates the attractive force of mathematics. $2.95

Introduction to Measure and Probability
J. F. C. KINGMAN and S. J. TAYLOR

This book sets out the theory of finite measures in general spaces, and gives an account of the fundamental theoretical ideas underlying the applications of probability in statistics and elsewhere. For advanced undergraduates, graduates, statisticians and applied mathematicians.

"The point of view is refreshing, and the style is clear—even enchanting."—*Choice (ALA)* $12.50

Introduction to Probability and Statistics from a Bayesian Viewpoint — D. V. LINDLEY
Part 1: Probability — **Part 2: Inference**

"The style is both concise and leisurely, with room always found for careful explanation of mathematical points. The mathematical knowledge assumed of the reader includes calculus and a little matrix algebra, but no measure theory. The book will be accessible and attractive to graduate students of statistics and mathematics and to some advanced undergraduates, as well as to more experienced readers."—*Science* Part 1, $6.00 Part 2, $6.50

Mathematical Analysis: An Introduction
D. B. SCOTT and S. R. TIMS

Intended to widen and deepen understanding of the fundamental notions of the subject and to clarify the logical connections between them.

"Can be strongly recommended to students working alone and to anyone, student or teacher, who wants to widen his mathematical background . . . an important book which on the counts of clarity, precision and richness of content will be very hard to beat."—*Times Educational Supplement* $9.50

Homology Theory: An Introduction to Algebraic Topology — P. J. HILTON and S. WYLIE

Now available for the first time in paperback.

"It does an excellent job of carrying the serious beginning student of algebraic topology to a genuine acquaintance with the field."—*Mathematical Reviews*

Cloth $13.50 Paper $3.95

Cambridge University Press

32 East 57th Street, New York, N.Y. 10022

Paperbound Supplements For Your Spring Classes

. . . devoted to topics which should be thoroughly understood in the early stages of mathematics learning. These supplements will enrich a variety of courses and facilitate instructional flexibility in the departments of mathematics and education, as well as physics, psychology, and engineering.

1967: MODERN ELEMENTARY MATHEMATICS: A PROGRAMMED INTRODUCTION

By Robert M. Todd, Department of Education, Boston, University; and Cecil W. McDermott, Department of Mathematics, Hendrix College. A supplement or possible base text in the department of education, explores such important concepts as set notation and properties, the numeration system, and a development of the real number system, in accordance with the CUPM level I recommendations. 6 x 9 paperbound, 292 pp.

1967: INDUCTIVE CALCULUS

By Eugene V. Petrik, Chairman of the Physics Department, Seton Hall University. Considers calculus and vector analysis as "sensible" approaches to important problems in science, psychology and business. Technical language is de-emphasized. Intensively studied are the derivative, the anti-derivative, and the definite integral. 5⅝ x 8⅜ paperbound, 278 pp.

The Allyn and Bacon Series: Topics in Contemporary Mathematics

Topics are chosen for fundamental importance and interest to both professor and student.

1967: INFORMAL LOGIC

By John W. Kenelly, Clemson University. Meaningful at any stage of undergraduate work, develops the basic concepts of symbolic logic relevant to mathematical theorems and proofs. An important divergence from most available material is the lack of interest in achieving a formal logic format, as the purpose here is to use logical inferences and valid substitution within mathematical proofs. 5⅝ x 8⅜ paperbound, 134 pp.

1966: SETS WITH APPLICATIONS

By Peter W. Zehna, U.S. Naval Postgraduate School. "A well written, thorough presentation of sets."—Richard Lee Barlow, Butler University. Shows the role of set theory in current mathematical development; then deals with the logic needed to construct simple proofs. 6 x 9 paperbound, 153 pp.

1966: ALGEBRA THROUGH PROBLEM SOLVING

By Abraham P. Hillman, University of New Mexico; and Gerald L. Alexanderson, University of Santa Clara. Teaches the reader to recognize mathematical patterns, and to prove analogies and generalizations of known results. Appropriate introductory level topics highlight the interdependence of mathematical concepts. 5⅝ x 8⅜ paperbound, 129 pp.

ALLYN & BACON, INC., 470 ATLANTIC AVENUE, BOSTON, MASSACHUSETTS 02210

ALLYN & BACON, Inc.

Basic Mathematics Texts For a Variety of Needs

Science and Engineering

1967: INTRODUCTION TO VECTOR ANALYSIS, SECOND EDITION

By Harry F. Davis, University of Waterloo. Like the very successful first edition, imparts sound geometrical and physical understanding to basic ideas. Requiring a minimal background, it distinguishes itself from other texts on vector analysis by added emphasis on motivation and on the intuitive content of more difficult concepts. 6 x 9, 349 pp.

Science and Engineering

1967: ELEMENTS OF STATISTICAL INFERENCE, SECOND EDITION

By David V. Huntsberger, Iowa State University of Science and Technology. Gives students with little mathematical background a sound understanding of the language and broadly applicable techniques from statistical inference. The new edition is enhanced by a greater number of problems and illustrations from all areas of application. 6 x 9. 398 pp.

Mathematics, Science, and Engineering

1966: CONCEPTS AND METHODS OF EXPERIMENTAL STATISTICS

By H. C. Fryer, Kansas State University. "An interesting and complete text. . . . The topics are clearly presented with good examples."—G. I. Chase, Indiana University. "Reads easily, and what the author says is well done—especially pisbit analysis and discriminatory analysis"—Kenneth R. Eaton, Jr., University of Michigan. 6 x 9, 602 pp., 40 pp. of tables.

Psychology

1966: FUNDAMENTALS OF EXPERIMENTAL DESIGN

By Jerome L. Myers, University of Massachusetts. "Recipes for designs and analyses are in themselves not sufficient for the training of independent researchers. It is hoped that the development of this book will provide a basis for selecting among designs and analyses which are not discussed here."—THE PREFACE. 6 x 9¼, 407 pp.

Mathematics, Science, Social Science, Business

1966: ELEMENTARY MATRIX THEORY

By Howard Eves, University of Maine. "It may be argued that matrices are primarily algebraical objects whose structure with regard to addition, multiplication and transposition should be studied in its own right. This is the point of view of the author. . . . The treatment is straightforward and requires no previous acquaintance with abstract algebra."—MATHEMATICAL REVIEWS. 6 x 9, 325 pp.

Mathematics

CALCULUS

By Richard E. Johnson, University of New Hampshire; and Fred L. Kiokemeister, Mount Holyoke College. Well established as a favorite calculus text, offers the student with a background in algebra, plane and analytic geometry, and trigonometry, a rigorous and intuitive introduction to calculus. 6 x 9, 634 pp.

ALLYN & BACON, INC., 470 ATLANTIC AVENUE, BOSTON, MASSACHUSETTS 02210

APPLICATIONS OF UNDERGRADUATE MATHEMATICS IN ENGINEERING

written and edited by Ben Noble

Mathematics Research Center, U. S. Army, University of Wisconsin

Based on 45 contributions submitted by engineers in universities and industries to the Committee on Engineering Education and the Panel on Physical Sciences and Engineering of CUPM. About 400 pages.

Each member of the Association may purchase one copy of this book for $4.50. Orders with remittance should be addressed to:

SEVEN JUNIOR-SENIOR LEVEL MATHEMATICS TEXTS FROM McGRAW-HILL

Four new titles in the International Series in Pure and Applied Mathematics . . .

INTRODUCTION TO PARTIAL DIFFERENTIAL EQUATIONS AND BOUNDARY VALUE PROBLEMS

By Rene Dennemeyer, *California State College.* Winter. This book covers on an elementary level: introduction to linear first- and second-order partial differential equations; the Cauchy problem for such equations, existence theorems, formal methods for finding the solution, and the role of characteristics; classical boundary- and initial-value problems for the wave equation; boundary-value problems for Laplace's equation, and boundary- and initial-value problems for the heat equation.

CONFORMAL MAPPING ON RIEMANN SURFACES

By Harvey Cohn, *University of Arizona.* 344 pages, $12.95. Unifies the various aspects of the Theory of Riemann Surfaces—more specifically the applied aspects as related to conformal mapping and the pure aspects as related to topology and algebraic functions. An outstanding feature is that the material is unified rather than specialized.

DIFFERENTIAL EQUATIONS WITH APPLICATIONS

By Paul D. Ritger and Nicholas J. Rose, *both Stevens Institute of Technology.* Winter. Presents theory in a careful, straightforward manner. The meaning of a solution and the conditions for existence and uniqueness are discussed thoroughly, and considerable emphasis is given to initial and boundary value problems, general properties of linear equations, and the differences between linear and nonlinear systems.

LINEAR ALGEBRA

By Walter Nef, *University of Berne, Switzerland.* English translation: J. C. Ault, *Leicester University England.* 305 pages, $12.00. Covers game theory and linear inequalities—two topics not usually covered in linear algebra books. Also discusses linear programming and Tchebycher approximations. The approach is mathematical, but the transition from theory to applications is simplified by the introduction of numerical techniques for the most important problems; all these techniques are based on the exchange method.

Three additional titles . . .

LINEAR SPACES OF ANALYTIC FUNCTIONS

By Pasquale Porcelli, *Louisiana State University.* 158 pages, $8.00. The central theme of this book is approximation theory. It will ground students in analytic function theory, acquaint them with frontiers of knowledge in certain areas of analysis, and familiarize them with some of the literature—both recent works and historical patterns.

ELEMENTARY METHODS IN ANALYTIC NUMBER THEORY

By A. E. Gelfond and U. V. Linnik, *both University of Moscow.* Translated by Amiel Feinstein. Revised and edited by L. J. Mordell, *Cambridge University.* 242 pages, $8.75. Collects many different and important aspects of number theory, focusing attention on those problems which can be solved by elementary means (i.e. without complex function theory).

FOUNDATIONS OF REAL NUMBERS

By Claude W. Burrill, *New York University.* 176 pages, $6.95. A unique book which patterns the primary definition of real numbers after the usual decimal representations of such numbers. Three methods of constructing real numbers are provided.

Important New Texts from Macmillan

First-Year Calculus

By Arthur B. Simon, Northwestern University

A rigorous and lively introduction to the study of single variable calculus, including infinite series and vectors, is provided by this important new text. The graded exercises form an integral part of the text and are of three kinds: drill, theoretical, and review. Answers to selected problems are provided at the end of the book.

1967, 465 pages, $9.95

Trigonometry: An Analytic Approach

By Irving Drooyan and Walter Hadel, both of Los Angeles Pierce College

Concepts and notations as well as a review of the real number system are presented in the first chapter of this thoroughly modern text. Each of the chapters contains graded exercises designated "A," "B," and "C," to permit greater instructional flexibility. A second color is used functionally throughout. Available gratis are a Teacher's Supplement, Solutions Manual, and Progress Tests.

1967, 308 pages, $5.50

Modern Plane Geometry for College Students

By Herman R. Hyatt and Charles C. Carico, both of Los Angeles Pierce College

This modern text for one semester courses meets the needs of both terminal students and majors. A careful distinction is made between geometric entities and their measures, and the concept of "proof" is given special attention. "A" or "A" and "B" sets of problems permit the instructor to use the text effectively in either three or five semester-hour courses. A second color is used functionally to illustrate ideas. Answers to odd-numbered problems appear in the appendix, and a Solutions Manual is available, gratis.

1967, 414 pages, $7.95

Mathematics for Elementary School Teachers

By Helen L. Garstens, and Stanley B. Jackson, both of the University of Maryland

This textbook centers on the development and structure of number systems and the basic concepts of geometry fundamental to an understanding of measure. A number of excellent pedagogical aids are included. A Teacher's Manual is also available, gratis.

1967, 500 pages, $9.95

Elements of Abstract Algebra Second Edition

By John T. Moore, University of Western Ontario

This text provides an introduction to the development of algebraic systems for courses in abstract or modern algebra. The author proceeds from a discussion of the set to systems with one binary composition, culminating with groups. Subsequently he discusses systems with two binary compositions such as rings, fields, vector spaces, and lattices. A new chapter on Field Extension and twice as many problem sets have been included in the Second Edition.

1967, 349 pages, $8.95

Introduction to Probability and Statistics, Second Edition

By B. W. Lindgren and G. W. McElrath, both of The University of Minnesota

This book introduces the elements of probability and the ideas of statistical inference. Sections requiring calculus are marked. Topics of special interest are inference for discrete cases, decision theory approach and likelihood methods. A Solutions Manual is available, gratis.

1966, 277 pages, $7.95

Write to the Faculty Service Desk for examination copies.

THE MACMILLAN COMPANY, 866 Third Avenue, New York, New York 10022

Announcing the publication of

Calculus and Linear Algebra

BURROWES HUNT, Reed College

This introductory textbook is designed to give liberal arts students some feeling for the nature of mathematics and to provide students of science and mathematics with a firm basis in the fundamentals of the subject. Emphasis is on concepts rather than techniques throughout the book.

The author first discusses the natural numbers and the real number system, including the basic theory of convergence of sequences. He next gives an introductory treatment of analytic geometry using the methods of linear algebra, and he then concludes by presenting a thorough and closely reasoned account of the elements of the calculus of functions of one real variable.

1967, 401 pages, 144 illustrations, $9.50

THE AMERICAN MATHEMATICAL MONTHLY

(FOUNDED IN 1894 BY BENJAMIN F. FINKEL)

R. A. ROSENBAUM, *Editor*

ASSOCIATE EDITORS

J. BARLAZ	RAOUL HAILPERN	GEORGE RANEY
J. A. BROWN	M. S. KLAMKIN	GIAN-CARLO ROTA
LEONARD CARLITZ	R. C. LYNDON	E. P. STARKE
HASKELL COHEN	ARTHUR MATTUCK	JAMES WENDEL
HOWARD EVES	K. O. MAY	ALBERT WILANSKY
HARLEY FLANDERS	J. R. MAYOR	

EDITORIAL CORRESPONDENCE should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with $\det [a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are \$6.00 (\$8.00 in 1968). For nonmembers the subscription price is \$10.00 (\$15.00 in 1968).

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

HIGHER CURVATURES OF CURVES IN EUCLIDEAN SPACE, II

HERMAN GLUCK, Harvard University and the University of Pennsylvania

1. Introduction. As presented in elementary calculus, the curvature of a plane curve is a quantity which measures the rate of turning of the tangent line to the curve. If $\vartheta(s)$ denotes the angle between a fixed line and the tangent line, then the curvature is defined to be the derivative $\vartheta'(s)$ of this angle with respect to arc length. In sharp contrast to this, the curvatures of a curve in n-space are defined in an altogether different manner via Frenet theory [1]. My object here is to show that even in this more general setting, the curvatures can equally well be defined as the rates of turning of the appropriate osculating planes.

2. Angles between p-planes in R^n. The early portions of this section are likely to be familiar to the reader, and are in any case straightforward, so the discussion is purposely sketchy. More details may be found in Chapter 4 of [2].

The angle between a pair of lines, P^1 and Q^1, in Euclidean n-space R^n is the smaller of the two possible angles between any vector parallel to P^1 and any vector parallel to Q^1. The angle between a line P^1 and a p-plane Q^p in R^n is the smallest angle between P^1 and any line in Q^p. This is the same as the angle between P^1 and its orthogonal projection in Q^p, or $\pi/2$ in case this orthogonal projection degenerates to a point.

Consider now a pair of p-planes, P^p and Q^p, in R^n. Suppose that among all pairs of lines, one from P^p and one from Q^p, the lines S^1 and T^1 make the smallest possible angle, ϑ_1, with each other. Let P^{p-1} and Q^{p-1} be "orthogonal complements" of S^1 and T^1 in P^p and Q^p, respectively. Then it is easily seen that S^1 is orthogonal not only to P^{p-1} but also to Q^{p-1}, and similarly T^1 is orthogonal not only to Q^{p-1} but also to P^{p-1}.

If we iterate this procedure with P^{p-1} and Q^{p-1} in the roles of P^p and Q^p, we get another angle $\vartheta_2 \geqq \vartheta_1$. Doing this p times in all, we get p angles

$$0 \leqq \vartheta_1 \leqq \vartheta_2 \leqq \cdots \leqq \vartheta_p \leqq \pi/2.$$

These angles depend only on P^p and Q^p, and not on the various choices possible during the above procedure, and are called the *principal angles* between P^p and Q^p.

The procedure also yields orthonormal bases $\{u_1, u_2, \cdots, u_p\}$ and $\{v_1, v_2, \cdots, v_p\}$ for the subspaces P_0^p and Q_0^p parallel to P^p and Q^p, such that

$$\prec u_i, v_i \succ = \cos\vartheta_i \quad \text{for } 1 \leqq i \leqq p$$
$$\prec u_i, v_j \succ = 0 \qquad \text{for } i \neq j.$$

These bases are said to be in *normal form*. Unlike the principal angles, they are not uniquely determined by the procedure. For example, u_i and v_i may simultaneously (or individually if $\vartheta_i = \pi/2$) be replaced by their negatives for assorted values of i. This is the only ambiguity possible if all the principal angles are distinct, but more variations can occur if some of the successive principal angles

coincide. Note, for future use, that the orthogonal projection of u_i into Q_0^p is $(\cos \vartheta_i)v_i$, and similarly the orthogonal projection of v_i into P_0^p is $(\cos \vartheta_i)u_i$.

If the positive integers $p \leqq n$ and the p angles

$$0 \leqq \vartheta_1 \leqq \vartheta_2 \leqq \cdots \leqq \vartheta_p \leqq \pi/2$$

such that

$$\vartheta_i = 0 \quad \text{for } 1 \leqq i \leqq 2p - n$$

are given in advance, then there exists a pair of p-planes P^p and Q^p in R^n for which these angles are the principal angles between P^p and Q^p. Furthermore, these angles determine the relative position of P^p and Q^p in the following sense.

THEOREM 2.1. *Let P^p, Q^p, $\overline{P}^p$ and $\overline{Q}^p$ be p-planes in R^n. Then there exists a linear isometry F: $R^n \to R^n$ such that $F(P^p)$ is parallel to $\overline{P}^p$ and $F(Q^p)$ is parallel to $\overline{Q}^p$ if and only if the principal angles between P^p and Q^p coincide with those between $\overline{P}^p$ and $\overline{Q}^p$.*

The necessity of the condition follows from the fact that the construction of principal angles depends only on angles in R^n, and not on actual position. The sufficiency is proved by finding a linear isometry F which takes a pair of bases in normal form for P_0^p and Q_0^p onto a corresponding pair for $\overline{P}_0^p$ and $\overline{Q}_0^p$, and this is just an exercise in linear algebra.

THEOREM 2.2. *Let P^p and Q^p be p-planes in R^n, and let $(P^p)^\perp$ and $(Q^p)^\perp$ be $(n-p)$-planes orthogonal to P^p and Q^p, respectively. Then the nonzero principal angles between $(P^p)^\perp$ and $(Q^p)^\perp$ coincide with the nonzero principal angles between P^p and Q^p.*

The proof is left to the reader.

Let P^p and Q^p be p-planes in R^n. Then there are p principal angles between P^p and Q^p, which determine the relative position of these p-planes in the sense of Theorem 2.1. Suppose that it is desired to find a *single* angle which might reasonably be called *the* angle between P^p and Q^p. If one were constrained to choose from among the principal angles, one would have to select the largest principal angle ϑ_p for such a role, in order to insure that P^p and Q^p are parallel if and only if the angle between them is zero. Such a constraint, however, is artificial.

In order to arrive at the right definition, consider carefully the familiar case when $p=1$. Then there is just one principal angle ϑ_1 between the lines P^1 and Q^1, and it coincides with the ordinary angle ϑ between these lines. This angle ϑ, lying between 0 and $\pi/2$, has the following important property: if U is any measurable subset of P^1 with one-dimensional (Euclidean) measure $\mu(U)$, then the orthogonal projection of U into Q^1 is also measurable and has one-dimensional measure $(\cos \vartheta)\mu(U)$ in Q^1. Similarly, if V is a measurable subset of Q^1 with measure $\mu(V)$, then the orthogonal projection of V into P^1 has measure $(\cos \vartheta)\mu(V)$ in P^1. Thus the angle ϑ between P^1 and Q^1 might be characterized as

that angle between 0 and $\pi/2$ whose cosine is the reduction factor for one-dimensional measure under orthogonal projection of P^1 into Q^1, or vice versa of Q^1 into P^1. If u_1 is a unit vector in P_0^1 and v_1 a unit vector in Q_0^1, then the (1×1) matrix of the orthogonal projection of P_0^1 into Q_0^1 has a determinant whose absolute value is $\cos\vartheta$, and similarly in the reverse direction.

These observations lead directly to

DEFINITION 2.3. *Let P^p and Q^p be p-planes in R^n. Let the number α, $0\leqq\alpha\leqq 1$, be the reduction factor for p-dimensional measure under orthogonal projection of P^p into Q^p. Then the unique angle ϑ, $0\leqq\vartheta\leqq\pi/2$, such that $\cos\vartheta=\alpha$, will be called the* angle between P^p and Q^p.

Two immediate consequences of this definition are

(2.4) *If P^p is parallel to $\overline{P}^p$ and Q^p is parallel to $\overline{Q}^p$, then the angle between P^p and Q^p is the same as the angle between $\overline{P}^p$ and $\overline{Q}^p$.*

(2.5) *If $\{u_1, u_2, \cdots, u_p\}$ is any unimodular basis for P_0^p and $\{v_1, v_2, \cdots, v_p\}$ is any unimodular basis for Q_0^p, then the determinant of the matrix of orthogonal projection of P_0^p into Q_0^p has absolute value equal to $\cos\vartheta$, where ϑ is the angle between P^p and Q^p, or equivalently between P_0^p and Q_0^p.*

Information about the angle between p-planes is obtained by relating this angle to the principal angles.

THEOREM 2.6. *Let P^p and Q^p be k-planes in R^n, and let $\vartheta_1\leqq\vartheta_2\leqq\cdots\leqq\vartheta_p$ be the principal angles between them. Then the angle ϑ between P^p and Q^p is given by $\cos\vartheta=(\cos\vartheta_1)(\cos\vartheta_2)\cdots(\cos\vartheta_p)$.*

Let $\{u_1, u_2, \cdots, u_p\}$ and $\{v_1, v_2, \cdots, v_p\}$ be bases for P_0^p and Q_0^p which are in normal form. Then

$$\begin{aligned} &\prec u_i, u_j\succ = \prec v_i, v_j\succ = \delta_{ij} \\ &\prec u_i, v_i\succ = \cos\vartheta_i \qquad \text{for } 1\leqq i\leqq p \\ &\prec u_i, v_j\succ = 0 \qquad \text{for } i\neq j. \end{aligned}$$

Since the orthogonal projection of u_i into Q_0^p is $(\cos\vartheta_i)v_i$, the matrix of this projection with respect to the above bases is simply a diagonal matrix, with diagonal entries

$$\cos\vartheta_1, \cos\vartheta_2, \cdots, \cos\vartheta_p.$$

Since orthonormal bases are certainly unimodular, the theorem now follows from (2.5) and (2.4).

Alternatively, we may observe that the cube in P_0^p with leading edges u_1, $u_2, \cdots, u_p$ and p-dimensional measure 1 goes under orthogonal projection into the rectangular parallelepiped in Q_0^p with leading edges $(\cos\vartheta_1)v_1$, $(\cos\vartheta_2)v_2, \cdots,$ $(\cos\vartheta_p)v_p$ and p-dimensional measure

$$(\cos\vartheta_1)(\cos\vartheta_2)\cdots(\cos\vartheta_p).$$

And again, the theorem follows.

Some immediate consequences of Theorem 2.6 are

(2.7) *The angle between P^p and Q^p is the same as the angle between Q^p and P^p.*

(2.8) *If ϑ_p is the largest principal angle between P^p and Q^p, then the angle ϑ between P^p and Q^p is trapped by the inequality $\vartheta_p \leqq \vartheta \leqq \pi/2$.*

(2.9) *The angle between P^p and Q^p is zero if and only if P^p and Q^p are parallel.*

(2.10) *If $(P^p)^\perp$ and $(Q^p)^\perp$ are $(n-p)$-planes orthogonal to P^p and Q^p, respectively, then the angle between $(P^p)^\perp$ and $(Q^p)^\perp$ is the same as the angle between P^p and Q^p.*

This last statement follows from Theorems 2.6 and 2.2.

Suppose now that P^p and Q^p are p-planes in R^n. Corresponding to these p-planes are one-dimensional subspaces L^1 and M^1 of the exterior product $\wedge^p R^n$, which consist of the decomposable p-vectors representing P_0^p and Q_0^p, respectively. The inner product on R^n induces an inner product on $\wedge^p R^n$ in a natural way, relative to which we shall compute the angle φ between L^1 and M^1.

To do this, we need only find a unit p-vector $x \in L^1$ and a unit p-vector $y \in M^1$ such that $\prec x, y \succ \geqq 0$. Then φ will be the unique angle between 0 and $\pi/2$ such that $\cos\varphi = \prec x, y \succ$.

Let $\{u_1, u_2, \cdots, u_p\}$ and $\{v_1, v_2, \cdots, v_p\}$ be bases for P_0^p and Q_0^p which are in normal form. Consider the p-vector $x = u_1 \wedge u_2 \wedge \cdots \wedge u_p$ in $\wedge^p R^n$. Using the inner product in $\wedge^p R^n$, we have

$$\prec x, x \succ = \det(\prec u_i, u_j \succ).$$

Since $\{u_1, u_2, \cdots, u_p\}$ is an orthonormal basis for P_0^p, the matrix $(\prec u_i, u_j \succ)$ is the $p \times p$ identity matrix, and therefore has determinant 1. Thus $\prec x, x \succ = 1$, so x is a unit p-vector in L^1. Similarly,

$$y = v_1 \wedge v_2 \wedge \cdots \wedge v_p$$

is a unit p-vector in M^1.

Now $\prec x, y \succ = \det(\prec u_i, v_j \succ)$. Since the bases for P_0^p and Q_0^p are in normal form, the matrix $(\prec u_i, v_j \succ)$ is a diagonal matrix with diagonal entries $\cos\vartheta_1$, $\cos\vartheta_2, \cdots, \cos\vartheta_p$. Thus

$$\prec x, y \succ = (\cos\vartheta_1)(\cos\vartheta_2) \cdots (\cos\vartheta_p),$$

and since this product is $\geqq 0$, the angle φ between L^1 and M^1 is the unique angle between 0 and $\pi/2$ satisfying

$$\cos\varphi = (\cos\vartheta_1)(\cos\vartheta_2) \cdots (\cos\vartheta_p).$$

Comparing this formula with Theorem 2.6, we have

THEOREM 2.11. *Let P^p and Q^p be p-planes in R^n, and let L^1 and M^1 be the corresponding one-dimensional subspaces of $\wedge^p R^n$. Then the angle between P^p and Q^p in R^n coincides with the angle between L^1 and M^1 in $\wedge^p R^n$.*

As a corollary, we have

(2.12) *If P_1^p, P_2^p and P_3^p are three p-planes in R^n, then the angle between P_1^p and P_3^p is less than or equal to the sum of the angles between P_1^p and P_2^p and between P_2^p and P_3^p.*

For Theorem 2.11 reduces this to the case $p=1$, where the statement is evident.

The above considerations also yield a practical technique for computing the angle between two p-planes in R^n.

THEOREM 2.13. *Let P^p and Q^p be p-planes in R^n, and let $\{u_1, u_2, \cdots, u_p\}$ and $\{v_1, v_2, \cdots, v_p\}$ be arbitrary bases for P_0^p and Q_0^p, respectively. Then the angle ϑ between P^p and Q^p is given by the formula*

$$\cos\vartheta = \frac{|\det(\prec u_i, v_j\succ)|}{\sqrt{\det(\prec u_i, u_j\succ)}\sqrt{\det(\prec v_i, v_j\succ)}}.$$

Consider the p-vectors

$$x = u_1 \wedge u_2 \wedge \cdots \wedge u_p \quad \text{and} \quad y = v_1 \wedge v_2 \wedge \cdots \wedge v_p,$$

which lie in the one-dimensional subspaces L^1 and M^1 of $\wedge^p R^n$ corresponding to P^p and Q^p. The angle φ between L^1 and M^1 is given by

$$\cos\varphi = \frac{|\prec x, y\succ|}{\sqrt{\prec x, x\succ}\sqrt{\prec y, y\succ}},$$

and the desired result then follows upon application of Theorem 2.11 and the explicit formulas for the inner product in $\wedge^p R^n$.

3. Curvature of curves via Frenet theory. Recall the situation of Frenet theory (see [1] for details). We have an interval $I \subset R^1$ and a map $F: I \to R^n$ which is a C^k parametrization by arc length. We assume that at each point $s \in I$, the derived vectors

$$F'(s), F''(s), \cdots, F^{[r]}(s) \qquad r < k$$

are linearly independent. Applying the Gram-Schmidt orthonormalization process to these vectors, we get an orthonormal r-frame

$$V_1(s), V_2(s), \cdots, V_r(s),$$

called the *Frenet r-frame*. The derivatives of the frame vectors satisfy the following *Frenet equations*.

$$(3.1) \qquad V_1'(s) = k_1(s)V_2(s)$$

$$(3.2) \qquad V_i'(s) = -k_{i-1}(s)V_{i-1}(s) + k_i(s)V_{i+1}(s), \qquad 2 \leqq i \leqq r-1.$$

$V_r'(s)$ exists because we have assumed that $r<k$, but there is a bit of trouble with a formula for it, because $V_{r+1}(s)$ may not exist. Given a point $s_0 \in I$, if

$F^{[r+1]}(s_0)$ happens to be linearly independent of $F'(s_0)$, $F''(s_0)$, $\cdots$, $F^{[r]}(s_0)$, then this will also be true for all s in some neighborhood of s_0. In that neighborhood, $V_{r+1}(s)$ can be defined by carrying the Gram-Schmidt process one step further, and we can then write

$$V_r'(s) = -k_{r-1}(s)V_{r-1}(s) + k_r(s)V_{r+1}(s). \tag{3.3}$$

Alternatively, if $F^{[r+1]}(s_0)$ happens to be linearly dependent on $F'(s_0)$, $F''(s_0)$, $\cdots$, $F^{[r]}(s_0)$, then $V_r'(s_0)$ will also be linearly dependent on $V_1(s_0)$, $V_2(s_0)$, $\cdots$, $V_r(s_0)$, and we will have

$$V_r'(s_0) = -k_{r-1}(s_0)V_{r-1}(s_0). \tag{3.4}$$

In this case, $k_r(s_0)$ is defined to be zero.

The *curvatures* associated with the given curve are defined to be the coefficients $k_1(s)$, $k_2(s)$, $\cdots$, $k_r(s)$ which appear in the Frenet equations. We have $k_i(s)>0$ for $1\leqq i\leqq r-1$, while $k_r(s)\geqq 0$.

4. Curvature as the rate of turning of the osculating planes. Let $1\leqq p\leqq r$. The subspace $P_0^p(s)$ of R^n spanned by the vectors $F'(s)$, $F''(s)$, $\cdots$, $F^{[p]}(s)$, or equally well by $V_1(s)$, $V_2(s)$, $\cdots$, $V_p(s)$, is called the *p-th osculating subspace* associated with the curve at the given point. The p-plane $P^p(s)$ in R^n which passes through $F(s)$ and is parallel to $P_0^p(s)$ is called the *osculating p-plane* to the curve at $F(s)$. At any given point, the curve has exactly pth order contact with its osculating p-plane for $p<r$ and at least pth order contact with its osculating p-plane for $p=r$. In this latter case, the order of contact will be greater than $p=r$ if and only if $k_r(s)=0$ at the point. In all cases, however, the curve has less than pth order contact with every other p-plane in R^n at $F(s)$. Thus the osculating planes to the curve at a given point are those planes with which the curve has closest contact at the point.

Fix the integer p, $1\leqq p\leqq r$, and fix a point s_0 in the domain of the curve. Consider the osculating p-plane $P^p(s)$, and define the angle $\vartheta(s)$ to be the angle between $P^p(s_0)$ and $P^p(s)$. We are now in a situation which generalizes that of elementary calculus (where $p=1$ and $n=2$), save for the fact that the angle $\vartheta(s)$ is unsigned. This is unavoidable, as can already be seen when $p=1$ and $n=3$, but is easily compensated for by taking right-hand instead of ordinary derivatives.

The following theorem shows that the curvatures measure the rates of turning of the osculating planes, and therefore may equally well be defined in a manner which directly generalizes that of elementary calculus.

THEOREM 4.1. *The angle $\vartheta(s)$ between the osculating p-planes $P^p(s_0)$ and $P^p(s)$ has a right-hand derivative at s_0, and $\vartheta'(s_0)=k_p(s_0)$.*

We first isolate a short computation.

LEMMA 4.2. *Let G: $[s_0, s_1]\to R^m$ be a function such that $|G(s)|=1$ for all $s\in[s_0, s_1]$. Let $\vartheta(s)$ denote the angle between the vectors $G(s_0)$ and $G(s)$. If G has a (necessarily right-hand) derivative at s_0 then so does ϑ, and $\vartheta'(s_0)=|G'(s_0)|$.*

We simply capitalize on the geometric equality

$$| G(s) - G(s_0) | = 2 \sin \frac{\vartheta(s)}{2} \cdot$$

Now

$$\lim_{s \downarrow s_0} \frac{\vartheta(s) - \vartheta(s_0)}{s - s_0} = \lim_{s \downarrow s_0} \frac{\vartheta(s)}{s - s_0} = \lim_{s \downarrow s_0} \frac{2 \sin(\vartheta(s)/2)}{s - s_0}$$

$$= \lim_{s \downarrow s_0} \frac{| G(s) - G(s_0) |}{s - s_0} = \lim_{s \downarrow s_0} \left| \frac{G(s) - G(s_0)}{s - s_0} \right|$$

$$= \left| \lim_{s \downarrow s_0} \frac{G(s) - G(s_0)}{s - s_0} \right| = | G'(s_0) | ,$$

and the lemma follows. Note that the validity of the step

$$\lim_{s \downarrow s_0} \frac{| G(s) - G(s_0) |}{s - s_0} = \lim_{s \downarrow s_0} \left| \frac{G(s) - G(s_0)}{s - s_0} \right|$$

depends on the fact that $s - s_0$ is positive, and this is where the one-sidedness of the derivatives makes its formal appearance.

Proof of Theorem 4.1. Consider the p-vector

$$x(s) = V_1(s) \wedge V_2(s) \wedge \cdots \wedge V_p(s). \tag{4.3}$$

Since $\{ V_1(s), V_2(s), \cdots, V_p(s) \}$ is an orthonormal basis for the pth osculating subspace $P_0^p(s)$, the p-vector $x(s)$ representing $P^p(s)$ has unit length in $\wedge^p R^n$. It follows from Theorem 2.11 that, for s close to s_0, the angle $\vartheta(s)$ between $P^p(s_0)$ and $P^p(s)$ is the same as the angle between $x(s_0)$ and $x(s)$. We will show that

$$| x'(s_0) | = k_p(s_0), \tag{4.4}$$

and then Theorem 4.1 will follow immediately from Lemma 4.2.

Since $p \leqq r < k$, each $V_i(s)$, $1 \leqq i \leqq p$, is differentiable. Now differentiate both sides of equation (4.3). The exterior product $\wedge$ in the exterior algebra $\wedge R^n$ is bilinear, hence the ordinary rule for differentiating a product is valid. Thus

$$x'(s) = \sum_{i=1}^{p} V_1(s) \wedge \cdots \wedge V_{i-1}(s) \wedge V_i'(s) \wedge V_{i+1}(s) \wedge \cdots \wedge V_p(s).$$

The Frenet formulas, together with the alternating character of multiplication in $\wedge R^n$ ($V \wedge V = 0$ for all $V \in R^n$), imply that all but the last term in the above summation are 0. Thus

$$x'(s) = V_1(s) \wedge \cdots \wedge V_{p-1}(s) \wedge V_p'(s).$$

If $p < r$, or if $p = r$ and $k_r(s) > 0$, we use Frenet formula (3.2) or (3.3) to obtain

$$x'(s) = V_1(s) \wedge \cdots \wedge V_{p-1}(s) \wedge [-k_{p-1}(s)V_{p-1}(s) + k_p(s)V_{p+1}(s)]$$
$$= k_p(s)[V_1(s) \wedge \cdots \wedge V_{p-1}(s) \wedge V_{p+1}(s)].$$

If $p=r$ and $k_r(s)=0$, we use Frenet formula (3.4) to write

$$x'(s) = V_1(s) \wedge \cdots \wedge V_{p-1}(s) \wedge [-k_{p-1}(s)V_{p-1}(s)] = 0.$$

In either case,

$$|x'(s)| = k_p(s), \tag{4.5}$$

since $V_1(s) \wedge \cdots \wedge V_{p-1}(s) \wedge V_{p+1}(s)$ is a unit p-vector in $\wedge^p R^n$. Letting $s=s_0$ we get equation (4.4), and the theorem now follows from Lemma 4.2.

Note that equation (4.5) reduces, for $p=1$, to the familiar formula

$$|V_1'(s)| = k_1(s),$$

which says that the first curvature of a curve is the absolute value of the derivative of the unit tangent vector with respect to arc length. Also observe that while $|x'(s)| = k_p(s)$ for all $s \in I$, $\vartheta'(s)$ will generally equal $k_p(s)$ only at $s=s_0$. An appropriate example is easily constructible for $p=1$ and $n=3$. The angle between two lines in the plane is known once the signed angle that each makes with a fixed line is known, but nothing like this is true for p-planes in n-space.

ON GENERATING FUNCTIONS AND A FORMULA OF CHAUDHURI

DAVID ZEITLIN, Minneapolis, Minnesota

1. Introduction. Recently, Chaudhuri [1] obtained the generalized formula

$$F_n(x) = \left(\frac{1-x^2}{1-y^2}\right)^{n/2} \sum_{k=0}^{n} \binom{n}{k} \left[\frac{x(1-y^2)^{1/2} - y(1-x^2)^{1/2}}{(1-x^2)^{1/2}}\right]^{n-k} \cdot F_k(y), \tag{1.1}$$

where, if

$$E(u) = \sum_{n=0}^{\infty} u^n/n!, \qquad G(u) = \sum_{n=0}^{\infty} g_n u^n, \qquad g_n \neq 0, \tag{1.2}$$

then $F_n(x)$ is defined by the generating function

ON SEMIGROUPS OF QUOTIENTS

B. M. PUTTASWAMAIAH, Carleton University, Ottawa

It was shown by Ore [1] that any right reversible cancellative semigroup can be embedded in a group. For an abelian semigroup this result can be generalized. The purpose of this note is to extend the later result for non-abelian case. This extension also applies for rings.

THEOREM 1. *Let G be a partially ordered semigroup and N be a subset in the centre of G such that $ax \leqq bx$ implies $a=b$, for any x in N. Then G can be embedded in a partially ordered semigroup with unity such that every element of N is positive.*

Proof. The semigroup S generated by N is contained in the centre of G and $ax \leqq bx$, $x \in S$ implies $a=b$. If for (a, s), (b, t) in $G \times S$, we define equality by $(a, s)=(b, t)$ if and only if $a=b$, $s=t$, and a relation by $(a, s) \sim (b, t)$ if and only if $at=bs$, then $\sim$ is an equivalence relation on $G \times S$. Let a/s be the equivalence class determined by (a, s). Let $G_S = \{a/s \mid a \in G, s \in S\}$. For a/s, b/t in G_S define $a/s \cdot b/t = ab/st$. This multiplication is well defined. For if $(a_1, s_1) \in a/s$ and $(b_1, t_1) \in b/t$, then $as_1 = a_1 s$ and $bt_1 = b_1 t$. These imply $a_1 b_1 st = ab s_1 t_1$, so that $(a_1 b_1, s_1 t_1) \sim (ab, st)$. Also multiplication is associative.

The element $s/s = \{(s, s) \mid s \in S\}$ is independent of s and

$$s/s \cdot b/t = sb/st = b/t = bs/ts = b/t \cdot s/s$$

for any b/t in G_S. Hence s/s is the unity of G_S.

The mapping $\phi: G \to G_S$ defined by $a\phi = sa/s$ is a homomorphism, since $ab\phi = sab/s = sa/s \cdot tb/t = a\phi \cdot b\phi$. If $a\phi = b\phi$, then $sa/s = tb/t$ implies $a = b$. Hence ϕ is a monomorphism. By identifying G with $G\phi$, we can regard G as being actually contained in G_S. An element of S (after identification) has the form st/s. But st/s, s/st are both members of G_S and satisfy $st/s \cdot s/st = s/s$. Thus G_S is a semigroup containing G such that every element of $N(\subset S)$ has an inverse in G_S.

For a/s, b/t in G_S, define $a/s \leqq b/t$ if and only if $at \leqq bs$. Again the relation $\leqq$ is well defined. For if $(a_1, s_1) \in a/s$, $(b_1, t_1) \in b/t$, then $a_1 s = a s_1$ and $b_1 t = b t_1$. Thus $a_1 st = a s_1 t \leqq b s s_1$; that is $a_1 t \leqq b s_1$ and $a_1 t t_1 \leqq b t_1 s_1 \leqq b_1 t s_1$. Hence $a_1 t_1 \leqq b_1 s_1$. Thus $\leqq$ is easily seen to be a partial order relation on G_S. If $a \leqq b$ in G, then $as \leqq bs$, so that $a/s \leqq b/s$ and conversely $as \leqq bs$ implies $a \leqq b$. Thus the partial order relation in G_S is an extension of the partial order relation in G.

Every element of S has an inverse. If P is the set of all elements of G_S which are greater than unity, then it is clear that every element of N is in P [2].

COROLLARY 1. *Every partially ordered abelian semigroup G with cancellation law can be embedded in a partially ordered abelian group such that every element of G is in the positive cone.*

COROLLARY 2. *If M is in the centre of a semigroup A and N is in the centre of semigroup B and if they satisfy the hypothesis of Theorem* 1, *then*

$$A_S \times B_T = (A \times B)_{S \times T}$$

where S is the semigroup generated by M, and T is the semigroup generated by N.

THEOREM 2. *Let N be a set of elements in the centre of a (multiplicative) semigroup G, such that $ax = bx$ implies $a = b$ for any x in N. Assume that G is also an additive abelian semigroup in which the right distributive law holds. Then G can be embedded in a (multiplicative) semigroup G_S with unity which is at the same time an additive abelian semigroup satisfying the right distributive law. If the cancellation law for addition holds in G then it holds in G_S. If the left distributive law holds in G, then it also holds in G_S.*

Proof. Let S be the semigroup generated by N. Then by Theorem 1, G can be embedded in a semigroup G_S with unity such that every element of N has an inverse. For a/s, b/t in G_S, define

$$a/s + b/t = at + bs/st.$$

This definition of addition is independent of the representatives of the equivalence classes. For if $(a_1, s_1) \in a/s$, $(b_1, t_1) \in b/t$, then $a_1 s = a s_1$ and $b_1 t = b t_1$ together imply $(a_1 t_1 + b_1 s_1)st = (at + bs)s_1 t_1$.

Next $(a/s + b/t)c/u = at + bs/st \cdot c/u = (at + bs)c/stu = act + bcs/stu = ac/su + bc/tu = a/s \cdot c/u + b/t \cdot c/u$. The other properties are similarly verified.

COROLLARY. *If G is an abelian semigroup with cancellation law in Theorem* 2,

it can be embedded in a semigroup with cancellation law which is also an additive abelian semigroup with cancellation law.

Example 1. Let G be the semigroup $\{r, 2r, 3r, \cdots\}$ where r is a natural number. If $N=\{r\}$, then $S=\{r^n \mid n=1, 2, 3, \cdots\}$ is a subsemigroup of G. Then G_S consists of all rational numbers of the form rm/r^n where $m, n=1, 2, 3, \cdots$.

THEOREM 3. *Let N be a set of elements in the centre of a (multiplicative) semigroup G, such that $ax=bx$ implies $a=b$ for any x in N. If G is an additive abelian semigroup with cancellation law satisfying the distributive laws, then G can be embedded in a ring $\overline{G}_S$ with unity such that every element of N has an inverse in the ring.*

Proof. Let S be the semigroup generated by N. Then S is in the centre of G and cancellation by elements of S holds. Let G_S be the semigroup constructed in Theorem 2. Every element of S has an inverse in G_S and G_S is an additive abelian semigroup with cancellation property. By Theorem 1, G_S can be embedded in an additive abelian group $\overline{G}_S$ as follows. For $(a/s, b/t)$, $(a'/s', b'/t')$ in $G_S \times G_S$, define $(a/s, b/t) \sim (a'/s', b'/t')$ if and only if $a/s+b'/t'=a'/s'+b/t$. Then $\sim$ is an equivalence relation on $G_S \times G_S$. Let $\overline{(a/s, b/t)}$ be the equivalence class determined by $(a/s, b/t)$ and $\overline{G}_S=\{\overline{(a/s, b/t)} \mid a, b \in G \text{ and } s, t \in S\}$. In $\overline{G}_S$ define

$$\overline{(a/s, b/t)} = \overline{(c/u, d/v)} = \overline{(a/s + c/u, b/t + d/v)}$$

and

$$\overline{(a/s, b/t)} \cdot \overline{(c/u, d/v)} = \overline{(ac/su + bd/tv, ad/sv + bc/tv)}.$$

The definitions of addition and multiplication are independent of the representatives of the equivalence classes. For if $(a_1/s_1, b_1/t_1) \in \overline{(a/s, b/t)}$ and $(c_1/u_1, d_1/v_1) \in \overline{(c/u, d/v)}$, then

(i) $$a_1/s_1 + b/t = a/s + b_1/t_1,$$

(ii) $$c_1/u_1 + d/v = c/u + d_1/v_1.$$

Adding (i) and (ii) one obtains

$$(a_1/s_1 + c_1/u_1) + (b/t + d/v) = (a/s + c/u) + (b_1/t_1 + d_1/v_1)$$

which implies that the addition is well defined. Again multiplying (i) by c_1/u_1 and d_1/v_1, and (ii) by a/s and b/t, then adding them, we get

$$(a_1c_1/s_1u_1 + b_1d_1/t_1v_1) + (ad/sv + bc/tu) = (ac/su + bd/tv) + (a_1d_1/s_1v_1 + b_1c_1/t_1u_1)$$

in view of the cancellation law. This proves that the multiplication does not depend on the representatives of the equivalence classes. It is easily verified that $\overline{G}_S$ is a ring, thus proving the theorem.

COROLLARY. *Let G be an abelian multiplicative semigroup with cancellation law, which is also an abelian additive semigroup with cancellation law, satisfying the distributive laws. Then G can be embedded in a field.*

Example 2. Let G be the semigroup of Example 1. Then it was seen that G_S consists of all rational numbers of the form rm/r^n where $m, n = 1, 2, 3 \cdots$. Then the ring $\overline{G}_S$ consists of all rational numbers of the form

$$rm/r^n$$

where $m = 0, \pm 1, \pm 2, \pm 3, \cdots$ and $n = 1, 2, 3, \cdots$.

ON THE FUNCTIONAL INEQUALITY $f(x+y) \geqq f(x)f(y)$

J. E. WETZEL, University of Illinois

G. Pólya [3, p. 103] has given an elegant little proof* of the arithmetic-geometric mean inequality based on the inequality $e^x \geqq 1+x$, as follows: Let $a_1, a_2, \cdots, a_n$ be nonnegative real numbers,

$$A = \frac{1}{n} \sum_{k=1}^{n} a_k$$

their arithmetic mean, and $G = (\prod_{k=1}^{n} a_k)^{1/n}$ their geometric mean. The case $A = 0$ being trivial, we suppose that $A > 0$. Then for each $k = 1, 2, \cdots, n$,

$$\exp\left\{\frac{a_k}{A} - 1\right\} \geqq \frac{a_k}{A} \geqq 0.$$

Noting that the exponents on the left sum to 0, we multiply these n inequalities together and get

$$1 = e^0 = \exp\left\{\sum_{k=1}^{n}\left(\frac{a_k}{A} - 1\right)\right\} = \prod_{k=1}^{n} \exp\left\{\frac{a_k}{A} - 1\right\} \geqq \prod_{k=1}^{n} \frac{a_k}{A} = \frac{G^n}{A^n}$$

and $A \geqq G$. Since the equality $e^x = 1+x$ holds if and only if $x = 0$, the equality $A = G$ holds if and only if $a_k = A$ for each k.

The role of the exponential function in this argument could be played as well by any function f with the properties

* In a letter to the author dated January 31, 1967, Pólya wrote, "I had, especially in younger years, quite often mathematical dreams, but, usually, on awakening, the mirage dissolved and nothing tangible remained. The proof for the theorem of the means . . . is perhaps the only proof which I saw in a dream (when I was an undergraduate, perhaps 20 years old) and which on awakening turned out to be solid stuff." He has referred to it in conversations as "the best mathematics I ever dreamed."

$$f(x+y) \geqq f(x)f(y), \tag{1}$$

$$f(x) \geqq 1 + x. \tag{2}$$

The purpose of this note is to show that the *only* function f defined on an interval about 0 that satisfies both (1) and (2) on that interval is the function $f(x)=e^x$. An extension of this result and some related examples concerning the functional inequality (1) are also included.

THEOREM 1. *Let f be an arbitrary real function defined on an open interval I about 0 that satisfies* (1) *and* (2) *whenever x, y, and $x+y$ belong to I. Then $f(x)=e^x$ for each x in I.*

Proof. By (1), $f(x)=f((x/2)+(x/2))\geqq[f(x/2)]^2\geqq 0$ for each x in I. Thus if $f(x_0)=0$, then $f(x_0/2)=0$, and by induction, $f(2^{-n}x_0)=0$ for each positive integer n. But (2) demands that $f(x)>0$ near 0. It follows that $f(x)>0$ for every x in I.

Next we show that f must be differentiable at each point x of I and that $f'(x)=f(x)$. Using (1) and (2) we see that for small h,

$$f(x+h) - f(x) \geqq f(x)[f(h) - 1] \geqq hf(x).$$

Since $f(x)=f(x+h-h)\geqq f(x+h)f(-h)\geqq f(x+h)(1-h)$, we have similarly for small h,

$$f(x+h) - f(x) \leqq f(x)\left[\frac{1}{1-h} - 1\right] = h\,\frac{f(x)}{1-h}\,.$$

Thus for small, positive h,

$$f(x) \leqq \frac{f(x+h) - f(x)}{h} \leqq \frac{f(x)}{1-h}$$

and the reverse inequalities hold for small, negative h. Hence

$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}$$

exists and equals $f(x)$ for each x in I.

It follows that

$$\frac{d}{dx}\, e^{-x}f(x) = e^{-x}[f'(x) - f(x)] = 0$$

for every x in I, and so $f(x)=Ce^x$ for some constant C. Since (1) implies $f(0)\leqq 1$ and (2) implies $f(0)\geqq 1$, we have $C=f(0)=1$, proving the theorem.

We can generalize this result somewhat by relaxing condition (2).

THEOREM 2. *Let f be a function defined on an open interval I about* 0 *such that* (1) *holds whenever x, y, and $x+y$ belong to I. If f is bounded below by a function*

g that is differentiable at 0 *and satisfies* $g(0)=1$, *then* $f(x)=e^{kx}$ *for all* x *in* I, *where* $k=g'(0)$.

Proof. For convenience, we put $g(x)=1+\phi(x)$, so that $\phi(0)=0$, $\phi'(0)=g'(0)=k$, and $f(x)\geqq 1+\phi(x)$ for all x in I. Then precisely the same sequence of steps used in the proof of Theorem 1 yields the inequalities

$$\frac{\phi(h)}{h}f(x) \leqq \frac{f(x+h)-f(x)}{h} \leqq \frac{f(x)}{1+\phi(-h)}\,\frac{\phi(-h)}{-h}$$

for small, positive h and the reverse inequalities for small, negative h. It follows that f is differentiable, and $f'(x)=kf(x)$ for each x in I. Then $e^{-kx}f(x)$ has derivative zero on I and is therefore a constant C, and $f(x)=Ce^{kx}$. Since $C=f(0)=1$, the theorem is proved.

We noted above that $0\leqq f(0)\leqq 1$ is an immediate consequence of (1). Included in the theorem is the interesting assertion that the only solutions of (1) that are differentiable at 0 and take the extreme value $f(0)=1$ are exponentials.

COROLLARY 1. *If* f *satisfies* (1) *on* I, *if* $f(0)=1$, *and if* f *is differentiable at* 0, *then* $f(x)=e^{kx}$ *for all* x *in* I, *where* $k=f'(0)$.

The assumption in the hypotheses of this corollary that f be differentiable at 0 cannot be weakened to continuity, for the continuous function $f(x)=(1+|x|)^{-1}$ satisfies (1) for all x and y and fails to be differentiable only at $x=0$.

The situation should be compared with the state of affairs for the functional equation $f(x+y)=f(x)f(y)$. If f satisfies this equality for all real x and y, then the function $g=\log f$ satisfies the linear functional equation $g(x+y)=g(x)+g(y)$; and if f is assumed to be continuous (even at just one point), or if f is assumed to be bounded on some interval, or even if the graph of f is assumed not to be everywhere dense in the upper half-plane, then $g(x)=kx$ and $f(x)=e^{kx}$ for every x (see [1], p. 108ff. and the literature cited there for additional details and proofs).

No result similar to that of Corollary 1 can be expected in the other extreme case $f(0)=0$; *any* function f that vanishes for all nonpositive x, is monotonically increasing, and is bounded above by 1, satisfies (1). A more interesting example can be constructed as follows. Let h be any differentiable function on [5, 7] that satisfies $0\leqq h(x)\leqq 0.9$ and $h(5)=h'(5)=h(7)=h'(7)=0$. Define

$$f(x)=\begin{cases} 0 & \text{for } x<5 \\ h(x) & \text{for } 5\leqq x\leqq 7 \\ 0 & \text{for } 7<x<8 \\ 1-\exp\{-(8-x)^2\} & \text{for } x\geqq 8 \end{cases}$$

Then f is a differentiable function with $f(0)=0$ that satisfies (1) for all x and y.

Finally, it is worth recasting Theorem 2 as a result about the functional inequality

$$F(x+y) \leqq F(x) + F(y) \tag{3}$$

whose solutions were studied by Cooper [2, p. 428f.].

COROLLARY 2. *Let F be a function defined on an open interval I about 0 that satisfies (3) whenever x, y, and $x+y$ belong to I. If F is bounded above by a function G that is differentiable at 0 and satisfies $G(0)=0$ (and, in particular, if F is differentiable at 0 and satisfies $F(0)=0$), then $F(x)=kx$ for all x in I, where k is a constant.*

Proof. Apply the theorem to $f(x)=\exp\{-F(x)\}$ with $g(x)=\exp\{-G(x)\}$.

GENERAL SOLUTION OF "ISOMOMENT" FUNCTIONAL EQUATIONS

J. ACZEL, University of Waterloo, Canada

1. In [7] S. Kotz has found that all *continuous* solutions of the "isomoment" functional equation:

$$f\left(\sum_{i=1}^{n} x_i^m/n\right) = \sum_{i=1}^{n} f(x_i)^m/n, \tag{1}$$

satisfied for all $x_i \geqq 0$ $(i=1, 2, \cdots, n)$ and for fixed integers $m>1$, $n>1$, are

$$\begin{aligned} &f(x) = 0,\ f(x) = 1,\ f(x) = x; \\ &\text{and if } m \text{ is odd also } f(x) = -1,\ f(x) = -x. \end{aligned} \tag{2}$$

In the present note we show that—even without supposing continuity or any other regularity-property—the functions (2) *are the most general real solutions of* (1) (for all $x_i \geqq 0$ and for fixed integers $m>1$, $n>1$), or that *all real solutions of* (1) *are continuous* (which is *not* the case if $m=1$).

2. First we observe, that (1) can be written with

$$x_i^m/n = y_i\ (i = 1, 2, \cdots, n), \qquad f((ny)^{1/m})^m/n = g(y) \tag{3}$$

Now, by (10), (13) and (14) for all nonnegative x and for all nonnegative rational r, s

$$(15)\quad \begin{aligned} a((rx+s)^m) &= (a(rx+s)+b)^m - b = (ra(x)+sa(1)+b)^m - b \\ &= r^m a(x)^m + mr^{m-1}sa(x)^{m-1}a(1) + mr^{m-1}a(x)^{m-1}b + \cdots + (sa(1)+b)^m - b \end{aligned}$$

and also

$$(16)\quad \begin{aligned} a((rx+s)^m) &= a(r^m x^m + mr^{m-1}sx^{m-1} + \cdots + s^m) \\ &= r^m((a(x)+b)^m - b) + mr^{m-1}sa(x^{m-1}) + \cdots + s^m a(1). \end{aligned}$$

Since r, s are *arbitrary* nonnegative rationals, the coefficients of $r^{m-1}s$ and similarly those of r^{m-1} have to be equal in both expressions (15) and (16):

$$(17)\qquad ma(x^{m-1}) = ma(x)^{m-1}a(1)$$

and

$$(18)\qquad ma(x)^{m-1}b = 0.$$

If $m>1$, equation (18) shows that *either* $a(x)=0$ *or* $b=0$ while (17) shows that a *is bounded* (from below or above or 0 depending upon whether $a(1)$ is positive, negative or 0, respectively) if m is *odd* (because $a(x)^{m-1}\geqq 0$). Equation (13) shows also that a *is bounded* from below if m is even. But *every bounded solution of* (10) *is continuous* and

$$(19)\qquad a(x) = ax$$

with constant a (see, e.g., [2]).

So the following solutions remain possible:

(i) $a(x)=0$ and (by (13)) $b^m=b$, i.e., $b=0$ or $b=1$ or, if m is odd, $b=-1$ and thus by (11)

$$(20)\qquad f(x) = 0, \qquad (21)\qquad f(x) = 1$$

and in case of odd $m>1$

$$(22)\qquad f(x) = -1.$$

(ii) $b=0, f(x)=a(x)=ax$ (by (11) and (19)) and by (13) $ay^m=a^m y^m$ so $a^m=a$, i.e., either $a=0$ (which was taken care of already in case (i)) or $a=1$ or, if m is odd, also $a=-1$, thus

$$(23)\qquad f(x) = x$$

and in case of odd $m>1$ also

$$(24)\qquad f(x) = -x$$

are solutions of (1) and only these.—We summarize our results:

THEOREM. *All real solutions of the functional equation* (1)— *supposed valid for all nonnegative* $x_i (i=1, 2, \cdots, n)$ *and for fixed integers* $m>1$, $n>1$—*are con-*

tinuous. The functions (20), (21), (23), *and in case of odd m, also* (22) *and* (24) *satisfy* (1) *and only these.*

The result in case (ii) can also be formulated so:

COROLLARY. *All real solutions of the system (with fixed integer* $m>1$)

$$f(y_1+y_2)=f(y_1)+f(y_2) \quad \text{and} \quad f(x^m)=f(x)^m \tag{25}$$

of functional equations—where $x>0$ *while* y_1, y_2 *may run through all real or all nonnegative numbers—are continuous; they are* (20), (23) *and in case of odd m also* (24), *and only these.*

3. REMARK 1. *Neither the theorem nor the corollary is true if* $m=1$; because then (12) and (13) are trivially satisfied and so every function of the form (11) with $a(y)$ satisfying only (10) is a solution of (1) and every solution of (10) with $f(y)=a(y)$ satisfies the system (25) too. (10) has, however, also noncontinuous solutions for all real or for all nonnegative y_1, y_2 (see, e.g., [2], [3]).

REMARK 2. *The Lemma, Theorem, Corollary and Remark* 1 *remain true, if in their statements "nonnegative" is replaced by "positive."* In fact, 0 was substituted into (4) only in the proof of the lemma, but the lemma remains true also if 0 is not in the set of validity of (4), (see, e.g., [1], [2], [4]).

INEQUALITIES FOR ELLIPTIC FUNCTIONS

G. D. ANDERSON, Michigan State University

In recent papers in this MONTHLY P. L. Duren [4] and S. Fempl [6] have called attention to the apparent paucity of known inequalities involving elliptic functions. In this note, using well-known infinite product expansions, we compare the values of elliptic functions with those of closely associated trigonometric functions. We employ a similar method to present an inequality involving elliptic integrals. Most of these relations were encountered in the study of quasiconformal mappings in 3-space [1].

We show that the following inequalities hold for $0 \leqq k < 1$ and α real:

$$(1)\quad \frac{1}{2}\left(1 + \frac{2K}{\pi}\right) \leqq \coth\frac{\pi K'}{2K} \leqq \frac{2K}{\pi}, \qquad (3)\quad 1 \leqq \frac{sn((2K/\pi)\alpha, k)}{\sin\alpha} \leqq \frac{2K}{\pi},$$

$$(2)\quad \frac{2k'K}{\pi} \leqq \frac{cn((2K/\pi)\alpha, k)}{\cos\alpha} \leqq 1, \qquad (4)\quad \frac{2K}{\pi} \leqq \frac{tn((2K/\pi)\alpha, k)}{\tan\alpha} \leqq \frac{\pi}{2k'K},$$

$$(5)\quad 1 - k \leqq \frac{\sin\alpha}{sn((2K/\pi)\alpha, k)}\left[1 - k\, sn^2\left(\frac{2K}{\pi}\alpha, k\right)\right] \leqq \frac{\pi}{2K},$$

$$(6)\quad \frac{dn^2((2K/\pi)\alpha, k)}{cn^2((2K/\pi)\alpha, k)} \frac{\cos^2\alpha \cosh^2(\pi K'/2K)}{\cos^2\alpha + \sinh^2(\pi K'/2K)} \leqq 1,$$

where k is the modulus of the given elliptic functions and

$$K = \int_0^1 [(1 - t^2)(1 - k^2t^2)]^{-1/2}dt,$$

$$K' = K(k'), \qquad k' = (1 - k^2)^{1/2}.$$

By q we shall always mean Jacobi's Nome, $q = \exp(-\pi K'/K)$. The Nome increases with k, and $0 \leqq q < 1$ when $0 \leqq k < 1$.

To prove (1) we begin with the obvious series expansion

$$(7)\quad \coth\frac{\pi K'}{2K} = \frac{1+q}{1-q} = 1 + 2\sum_{n=1}^{\infty} q^n,$$

for $0 \leqq k < 1$. Next, it follows from the Fourier series for $dn\, u$ ([3], #908.03, [7], p. 286) that

$$(8)\quad \frac{2K}{\pi} = 1 + 4\sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}}$$

for $0 \leqq k < 1$. Thus by (7) and (8) we see that

$$\frac{1}{2}\left(1 + \frac{2K}{\pi}\right) = 1 + 2\sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}} \leqq 1 + 2\sum_{n=1}^{\infty} q^n = \coth\frac{\pi K'}{2K}$$

From this we easily deduce that

$$\frac{1}{sn^2((2K/\pi)\alpha, k)} \frac{\sin^2 \alpha \cosh^2 (\pi K'/2K)}{\sin^2 \alpha + \sinh^2 (\pi K'/2K)} \leqq 1.$$

Replacing α by $\alpha+\pi/2$ in this expression and using the identity $sn(u+K) = (cn\ u)/(dn\ u)$ ([2], p. 13, [3], #122.03) yields (6). There is equality when $\alpha=\pi/2$.

THE GENERAL SOLUTION OF AN ARBITRARY BOOLEAN EQUATION

HELEN SKALA, Illinois Institute of Technology

If B is a Boolean algebra with operations union $\cup$, intersection $\cap$ and complementation $'$, then it is well known (cf., e.g., [6]) that B is a ring with regard to addition and multiplication defined as follows:

$$a + b = (a \cap b') \cup (a' \cap b) \quad \text{and} \quad ab = a \cap b.$$

Commutativity and associativity of addition (usually called symmetric difference) and distributivity of multiplication over addition are easily shown. The zero element of B considered as a ring is the zero element of B corresponding to union, i.e., the element 0 such that $0 \cup a = a$ for all a in B. For $a+0 = (a \cap 0') \cup (a' \cap 0) = a$. The additive inverse of any element a is a, and the complement of a is $1+a$, where 1 is the identity of B corresponding to intersection, i.e., the element such that $1 \cap a = a$ for all a in B. Union may be expressed in terms of addition and multiplication since

$$(1) \qquad a \cup b = (a' \cap b')' = 1 + (1 + a)(1 + b) = a + b + ab.$$

From this we easily deduce that

$$\frac{1}{sn^2((2K/\pi)\alpha, k)} \frac{\sin^2 \alpha \cosh^2 (\pi K'/2K)}{\sin^2 \alpha + \sinh^2 (\pi K'/2K)} \leqq 1.$$

Replacing α by $\alpha+\pi/2$ in this expression and using the identity $sn(u+K) = (cn\ u)/(dn\ u)$ ([2], p. 13, [3], #122.03) yields (6). There is equality when $\alpha=\pi/2$.

This work was supported in part by the National Science Foundation, Grant 18913. The material is included in a Ph.D. thesis written under the direction of Professor F. W. Gehring at the University of Michigan.

THE GENERAL SOLUTION OF AN ARBITRARY BOOLEAN EQUATION

HELEN SKALA, Illinois Institute of Technology

If B is a Boolean algebra with operations union $\cup$, intersection $\cap$ and complementation $'$, then it is well known (cf., e.g., [6]) that B is a ring with regard to addition and multiplication defined as follows:

$$a + b = (a \cap b') \cup (a' \cap b) \quad \text{and} \quad ab = a \cap b.$$

Commutativity and associativity of addition (usually called symmetric difference) and distributivity of multiplication over addition are easily shown. The zero element of B considered as a ring is the zero element of B corresponding to union, i.e., the element 0 such that $0 \cup a = a$ for all a in B. For $a+0 = (a \cap 0') \cup (a' \cap 0) = a$. The additive inverse of any element a is a, and the complement of a is $1+a$, where 1 is the identity of B corresponding to intersection, i.e., the element such that $1 \cap a = a$ for all a in B. Union may be expressed in terms of addition and multiplication since

$$(1) \qquad a \cup b = (a' \cap b')' = 1 + (1 + a)(1 + b) = a + b + ab.$$

The ring properties of a Boolean algebra may be exploited with great advantage in the theory of Boolean equations. For in absence of cancellation laws for union and intersection, the cancellation law for addition becomes highly significant in simplifying and solving Boolean equations. Conditions for unique solvability of Boolean equations, for instance, have been obtained by Parker and Bernstein (cf. [4]) in terms of the ring operations of a Boolean algebra.

Frequently, however, one is interested in determining *all* solutions to some Boolean equation. One description of the solutions of an equation in n unknowns has been in parametric form, that is, by means of a family of n Boolean functions $\{f_i; i=1, \cdots, n\}$ satisfying the conditions:

(1) For every $t_1^*, \cdots, t_n^*$ in B, the elements $x_i^*=f_i(t_1^*, \cdots, t_n^*)$ is a solution of the given equation.

(2) If $(x_1^*, \cdots, x_n^*)$ is a solution of the given equation then there exist $t_1^*, \cdots, t_n^*$ in B such that $x_i^*=f_i(t_1^*, \cdots, t_n^*)$.

For example, the equation $x \cup a=1$ has the general solution $x=a' \cup k$ where k is an arbitrary element. Numerous examples of various types of Boolean equations with their general solutions may be found in [1]. More generally, Motinori Gotō in [2] has enumerated all solutions of an arbitrary equation in the two-element Boolean algebras and in [3] extended his results to the case of finite Boolean algebras. Sergei Rudeanu (cf. [5]) then proved that the results obtained in [3] are still valid in any Boolean algebra. Rudeanu's method of solution, essentially due to Gotō, was to first express the equation in complete disjunctive form and then to determine the family of functions mentioned above in terms of the coefficients appearing in the disjunctive form.

Similar results may be obtained in a very easy manner by making use of the ring properties of a Boolean algebra. By (1), each Boolean equation may be written using only the operations addition and multiplication. By use of the distributive and cancellation laws, any Boolean equation in one unknown x may be written as

$$ax = b. \tag{2}$$

For example, the equation $cx \cup dx'=ex$ which in view of $cx \cup dx'=cx+dx'$ $cdxx'=cx+d(1+x)=(c+d)x+d$ is equivalent to $(c+d+e)x=d$. So in order to solve the general Boolean equation in one unknown one need only find all solutions of (2). In order that (2) have a solution, it is necessary and sufficient that

$$ab = b. \tag{3}$$

If (3) is satisfied, all solutions of (2) will be given by

$$x = a'k + b, \tag{4}$$

where k is an arbitrary element of B. That (4) is indeed a solution is readily verified since $a(a'k+b)=ab=b$. Now suppose x^* is a solution of (2). Then letting $k=x^*+b$, we have

$$a'(x^* + b) + b = a'x^* + a'b + b = (a + 1)x^* + (a + 1)b + b = ax^* + x^* + ab = x^*$$

$$x(a + aby) = c + by. \tag{7}$$

Solving first for x one obtains

$$x = (a + aby)'k_1 + c + by. \tag{8}$$

The necessary condition (3) becomes $y(abc+b) = ac+c$ whose solutions are given by

$$y = (abc + b)'k_2 + ac + c \tag{9}$$

provided

$$(abc + b)(ac + c) = ac + c. \tag{10}$$

Substituting in (8) the expression (9) for y, one obtains with the help of (10)

$$x = (a' + abck_2)k_1 + abck_2 + ac. \tag{11}$$

So whenever (10) is satisfied (7) will have solutions, namely, x and y given by (9) and (11), respectively.

MATHEMATICAL NOTES

MATRIX EXPRESSIONS IN RIGID BODY MECHANICS

M. N. Brearley, RAAF Academy, Victoria

In a recent Mathematical Education Note in this Monthly [1], R. K. Jarvis drew attention to the shortage of realistic applications of matrix theory at a level comprehensible to high school students, and appealed for examples of such applications. This note describes applications in mechanics which can be appreciated by a student whose knowledge of vector algebra extends only as far as the definitions of vector product and of the moment of a localized vector about a point. It also provides a method of bypassing the conventional dyadic or tensor treatment of the "inertia tensor" encountered when considering the rotation of a rigid body about a fixed point. The kinetic energy and angular

$$x(a + aby) = c + by. \tag{7}$$

Solving first for x one obtains

$$x = (a + aby)'k_1 + c + by. \tag{8}$$

The necessary condition (3) becomes $y(abc+b) = ac+c$ whose solutions are given by

$$y = (abc + b)'k_2 + ac + c \tag{9}$$

provided

$$(abc + b)(ac + c) = ac + c. \tag{10}$$

Substituting in (8) the expression (9) for y, one obtains with the help of (10)

$$x = (a' + abck_2)k_1 + abck_2 + ac. \tag{11}$$

So whenever (10) is satisfied (7) will have solutions, namely, x and y given by (9) and (11), respectively.

MATRIX EXPRESSIONS IN RIGID BODY MECHANICS

M. N. Brearley, RAAF Academy, Victoria

In a recent Mathematical Education Note in this Monthly [1], R. K. Jarvis drew attention to the shortage of realistic applications of matrix theory at a level comprehensible to high school students, and appealed for examples of such applications. This note describes applications in mechanics which can be appreciated by a student whose knowledge of vector algebra extends only as far as the definitions of vector product and of the moment of a localized vector about a point. It also provides a method of bypassing the conventional dyadic or tensor treatment of the "inertia tensor" encountered when considering the rotation of a rigid body about a fixed point. The kinetic energy and angular

where $I=-\Sigma mS_r^2$. In this notation the appropriate name for I is the inertia matrix of the body at O. It is easily verified that I has the expected component form

$$I=\begin{bmatrix} A & -H & -G \\ -H & B & -F \\ -G & -F & C \end{bmatrix}$$

in terms of the usual moments and products of inertia of the body with respect to the axes at O. In more conventional notations I is called the inertia dyadic or inertia tensor at O [2], and in dyadic notation (3) would be written

$$T=\tfrac{1}{2}\omega\cdot I\cdot\omega.$$

The transformation of axes by rotation to principal axes of the body at O may now be discussed in terms of the diagonalization of the matrix I by orthogonal transformation.

The angular momentum about O of the rotating body. This is denoted and defined by the moment sum

$$\boldsymbol{h}=\Sigma\boldsymbol{r}\times m\boldsymbol{v}=-\Sigma m\boldsymbol{r}\times(\boldsymbol{r}\times\omega).$$

Using the representation (1) this becomes

$$\begin{aligned}\boldsymbol{h} &= -\Sigma mS_r(S_r\omega),\\ &= -(\Sigma mS_r^2)\omega,\\ &= I\omega,\end{aligned}$$

where I is the inertia matrix at O. The corresponding dyadic notation is $\boldsymbol{h}=I\cdot\omega$.

A NOTE ON DIRECT PRODUCTS OF FREE MODULES

J. S. HAINES, New Mexico State University

An elegant characterization of those rings R such that the direct product of any family of projective R-modules is projective is given by S. Chase in [1]. (All rings have identities and all modules are left unitary.) However, Chase noted [1, page 467] that it was not known whether such a ring R had the property that the direct product of any family of free R-modules was free. This question turns out to be largely set-theoretical, and is settled in the negative in this note.

Let R and S be rings, $R\oplus S=T$ be the ring direct sum, and $\Pi_\alpha T$ ($\Sigma_\alpha T$) the direct product (sum) of α copies of T, with everything considered as a T-module.

If $\Pi_\alpha T$ is free, then $\Pi_\alpha T \approx \Sigma_\beta T$ for some cardinal β. Letting $|X|$ denote the cardinal of the set X, and α, R, and S be infinite, then

$$|R(\Pi_\alpha T)| = |\Pi_\alpha R| = |R|^\alpha = |R\Sigma_\beta T| = |\Sigma_\beta R| = \beta|R|, \text{ and } |S|^\alpha = \beta|S|.$$

Thus to answer the question in the negative, it suffices to find infinite rings R and S, and an infinite cardinal α such that products of projective T-modules are projective, but such that the equations $|R|^\alpha = \beta|R|$ and $|S|^\alpha = \beta|S|$ have no simultaneous solution for β. This can be accomplished by letting R be a field with $|R| = \chi_\omega$ (such a field clearly exists), S be a field with $|S| = \chi_0$, and $\alpha = \chi_0$. For then, $|R|^{\chi_0} > |R|$, β must be $|R|^{\chi_0}$, but $|R|^{\chi_0}|S| > |S|^{\chi_0}$. Since products of projective $R \oplus S$ modules are projective [1, Theorem 3.4], $B \oplus S$ is the desired example.

This work was supported by NSF GP-377.

A CURIOSITY IN MEASURE THEORY

MAURICE MACHOVER, St. John's University

Below is presented an interesting curiosity in the theory of Lebesgue Measure in E^n. The result may be formulated as follows: If the outer measure of two sets is additive, then so is their inner measure; but the converse is not true. In addition to the usual definitions, the proof is based on the following properties of outer and inner measure, all of which may be found in [1] (all sets are assumed to have finite outer measure):

(1) If $m^*(E_1 \cap E_2) = 0$, then

$$m^*(E_1) + m^*(E_2) \geqq m^*(E_1 \cup E_2) \geqq \begin{matrix} m_*(E_1) + m^*(E_2) \\ m^*(E_1) + m_*(E_2) \end{matrix} \geqq m_*(E_1 \cup E_2)$$
$$\geqq m_*(E_1) + m_*(E_2).$$

(2) If E is any set, there are measurable sets F and G such that

$$F \subseteq E \subseteq G \quad \text{and} \quad m(F) = m_*(E),\ m(G) = m^*(E).$$

(3) If E_1 and E_2 are measurable, $m(E_1 \cup E_2) + m(E_1 \cap E_2) = m(E_1) + m(E_2)$. It is immediately clear from (1) that addition or subtraction of a set of measure zero does not alter the outer or inner measure of a set.

LEMMA. *Let E_1 and E_2 be given sets. Then $m^*(E_1 \cup E_2) = m^*(E_1) + m^*(E_2)$ if and only if there exist measurable sets M_1 and M_2 such that $E_1 \subseteq M_1$, $E_2 \subseteq M_2$, and $m(M_1 \cap M_2) = 0$.*

If $\Pi_\alpha T$ is free, then $\Pi_\alpha T \approx \Sigma_\beta T$ for some cardinal β. Letting $|X|$ denote the cardinal of the set X, and α, R, and S be infinite, then

$$|R(\Pi_\alpha T)| = |\Pi_\alpha R| = |R|^\alpha = |R\Sigma_\beta T| = |\Sigma_\beta R| = \beta|R|, \text{ and } |S|^\alpha = \beta|S|.$$

Thus to answer the question in the negative, it suffices to find infinite rings R and S, and an infinite cardinal α such that products of projective T-modules are projective, but such that the equations $|R|^\alpha = \beta|R|$ and $|S|^\alpha = \beta|S|$ have no simultaneous solution for β. This can be accomplished by letting R be a field with $|R| = \chi_\omega$ (such a field clearly exists), S be a field with $|S| = \chi_0$, and $\alpha = \chi_0$. For then, $|R|^{\chi_0} > |R|$, β must be $|R|^{\chi_0}$, but $|R|^{\chi_0}|S| > |S|^{\chi_0}$. Since products of projective $R \oplus S$ modules are projective [1, Theorem 3.4], $B \oplus S$ is the desired example.

This work was supported by NSF GP-377.

A CURIOSITY IN MEASURE THEORY

MAURICE MACHOVER, St. John's University

Below is presented an interesting curiosity in the theory of Lebesgue Measure in E^n. The result may be formulated as follows: If the outer measure of two sets is additive, then so is their inner measure; but the converse is not true. In addition to the usual definitions, the proof is based on the following properties of outer and inner measure, all of which may be found in [1] (all sets are assumed to have finite outer measure):

(1) If $m^*(E_1 \cap E_2) = 0$, then

$$m^*(E_1) + m^*(E_2) \geqq m^*(E_1 \cup E_2) \geqq \begin{matrix} m_*(E_1) + m^*(E_2) \\ m^*(E_1) + m_*(E_2) \end{matrix} \geqq m_*(E_1 \cup E_2)$$
$$\geqq m_*(E_1) + m_*(E_2).$$

(2) If E is any set, there are measurable sets F and G such that

$$F \subseteq E \subseteq G \quad \text{and} \quad m(F) = m_*(E),\ m(G) = m^*(E).$$

(3) If E_1 and E_2 are measurable, $m(E_1 \cup E_2) + m(E_1 \cap E_2) = m(E_1) + m(E_2)$. It is immediately clear from (1) that addition or subtraction of a set of measure zero does not alter the outer or inner measure of a set.

LEMMA. *Let E_1 and E_2 be given sets. Then $m^*(E_1 \cup E_2) = m^*(E_1) + m^*(E_2)$ if and only if there exist measurable sets M_1 and M_2 such that $E_1 \subseteq M_1$, $E_2 \subseteq M_2$, and $m(M_1 \cap M_2) = 0$.*

Proof. Suppose such sets M_1 and M_2 exist. Given $\epsilon>0$, choose O, open, $\ni (E_1\cup E_2)\subseteq O$ and $m(O)<m^*(E_1\cup E_2)+\epsilon$. Now

$$E_1 \subseteq M_1 \cap O,\ E_2 \subseteq M_2 \cap O, \quad \text{and} \quad m[(M_1 \cap O) \cap (M_2 \cap O)] = 0.$$

Thus

$$\begin{aligned} m^*(E_1) + m^*(E_2) &\leqq m(M_1 \cap O) + m(M_2 \cap O) = m[(M_1 \cap O) \cup (M_2 \cap O)] \\ &= m[(M_1 \cup M_2) \cap O] \leqq m(O) < m^*(E_1 \cup E_2) + \epsilon \\ &\leqq m^*(E_1) + m^*(E_2) + \epsilon. \end{aligned}$$

Since ϵ is arbitrary, $m^*(E_1)+m^*(E_2)=m^*(E_1\cup E_2)$.

Conversely, suppose $m^*(E_1)+m^*(E_2)=m^*(E_1\cup E_2)$. Let M_1 and M_2 be measurable $\ni E_1\subseteq M_1$, $E_2\subseteq M_2$, and $m(M_1)=m^*(E_1)$, $m(M_2)=m^*(E_2)$. Suppose $m(M_1\cap M_2)>0$. Then

$$\begin{aligned} m^*(E_1 \cup E_2) &= m^*(E_1) + m^*(E_2) = m(M_1) + m(M_2) \\ &= m(M_1 \cup M_2) + m(M_1 \cap M_2) > m(M_1 \cup M_2) \geqq m^*(E_1 \cup E_2), \end{aligned}$$

which is contradictory.

The main result of the paper can now be established.

THEOREM. *If* $m^*(E_1\cup E_2)=m^*(E_1)+m^*(E_2)$, *then* $m_*(E_1\cup E_2)=m_*(E_1)+m_*(E_2)$.

Proof. By the lemma $\exists M_1$, M_2, measurable, $\ni E_1\subseteq M_1$, $E_2\subseteq M_2$, and $m(M_1\cap M_2)=0$. Given $\epsilon>0$, choose Q, closed, $\ni Q\subseteq(E_1\cup E_2)$ and $m(Q)>m_*(E_1\cup E_2)-\epsilon$. Now $Q\cap M_1\subseteq E_1\cup(M_1\cap M_2)$, $Q\cap M_2\subseteq E_2\cup(M_1\cap M_2)$. Since $m[(Q\cap M_1)\cap(Q\cap M_2)]=0$, it follows that

$$\begin{aligned} m_*(E_1) + m_*(E_2) - \epsilon &\leqq m_*(E_1 \cup E_2) - \epsilon < m(Q) = m[Q \cap (M_1 \cup M_2)] \\ &= m[(Q \cap M_1) \cup (Q \cap M_2)] = m(Q \cap M_1) + m(Q \cap M_2) \\ &\leqq m_*[E_1 \cup (M_1 \cap M_2)] + m_*[E_2 \cup (M_1 \cap M_2)] \\ &= m_*(E_1) + m_*(E_2). \end{aligned}$$

Since ϵ is arbitrary, $m_*(E_1)+m_*(E_2)=m_*(E_1\cup E_2)$.

The converse of this theorem is not true, as the following counter-example will show. Let $I=[1, 2]$, $J=[5, 6]$. Let N be a nonmeasurable set of inner measure zero, and contained in $[3, 4]$. Then the sets $E_1=I\cup N$, $E_2=J\cup N$ constitute a counter-example.

DERIVATIVES OF THE JACOBI ELLIPTIC FUNCTIONS

D. A. PELLETT, U. S. Naval Postgraduate School, Monterey, California

Although it is not at all difficult to obtain the derivative of any of the twelve (Glaisher's notation) Jacobi elliptic functions, the following quickly memorized mnemonic device provides the result instantly. It is based on the following antisymmetric array

	c'	d'	n'	s'
c	0	$-m_1$	-1	-1
d	m_1	0	$-m$	-1
n	1	m	0	-1
s	1	1	1	0

in which the row and column indices appear in alphabetic order. Here m is the parameter, $m=k^2$, and $m_1=1-m$ is the complementary parameter. Prime denotes differentiation with respect to argument. Argument and parameter (or modulus) need not be displayed, but we will do so in the first example so as to eliminate any confusion in the mind of the reader. Let α, β, γ, δ stand for the letters c, d, n, s in any order. Then

$$\alpha\beta' = A_{\alpha\beta'}\cdot\gamma\beta\cdot\delta\beta,$$

where $A_{\alpha\beta'}$ is the element in the α-row β'-column of the array.

Example 1. $(d/dx)ds(x|m)=ds'=-1\cdot cs\cdot ns=-cs(x|m)ns(x|m)$

Example 2. $dc'=m_1\cdot nc\cdot sc$.

Memorizing the array is aided by noting that the subdiagonal is "em-one, em, one."

A CHARACTERIZATION OF ORTHOGONAL MATRICES

K. A. BUSH, Washington State University

The following elementary theorem has been of occasional use to the author in trying to decide whether a matrix about which some information is available but where the precise matrix is not known could possibly be orthogonal, and it is apparently not in the literature.

THEOREM. *An n-square real matrix $A=(a_{ij})$ is orthogonal if and only if, for any subsets L and M of $(1, \cdots, n)$,*

$$\sum_{j=1}^{n}\Big(\sum_{i\in L} a_{ij}\Big)\Big(\sum_{i\in M} a_{ij}\Big) = p, \tag{1}$$

where p is the number of elements in $L\cap M$.

Proof. If (1) holds, then choosing L and M as singletons we have that the

A CHARACTERIZATION OF ORTHOGONAL MATRICES

K. A. BUSH, Washington State University

The following elementary theorem has been of occasional use to the author in trying to decide whether a matrix about which some information is available but where the precise matrix is not known could possibly be orthogonal, and it is apparently not in the literature.

THEOREM. *An n-square real matrix $A=(a_{ij})$ is orthogonal if and only if, for any subsets L and M of* $(1, \cdots, n)$,

$$\sum_{j=1}^{n}\Big(\sum_{i\in L} a_{ij}\Big)\Big(\sum_{i\in M} a_{ij}\Big) = p, \tag{1}$$

where p is the number of elements in $L\cap M$.

Proof. If (1) holds, then choosing L and M as singletons we have that the

inner product is zero unless the two choices coincide while it is one if the choices agree. Now assuming that A is orthogonal we reverse the order of summation in (1). We secure:

$$\sum_{k\in M}\sum_{i\in L}\sum_{j} a_{ij}a_{kj}.$$

The summation on j yields the element in the (i, k) position in AA^T where A^T is the transpose of A. The summations over the index sets therefore yield the sum of the elements in that submatrix of AA^T whose rows are the rows in the index set L and whose columns are the columns in the index set M. But A orthogonal implies that this is a submatrix of the unit matrix, and therefore the only non-zero elements are on the main diagonal or precisely the number of common elements in the two index sets. We note that a similar theorem holds if the roles of rows and columns are interchanged by applying (1) to A^T.

A SET OF LINEARLY INDEPENDENT PERMUTATION MATRICES

G. R. BLAKLEY, SUNY at Buffalo, W. E. COPPAGE, Wright State University,
R. D. DIXON, Wright State University

The set Ω_n of doubly stochastic n by n matrices is a convex polyhedron whose vertices are the n by n permutation matrices. The maximal dimension of any simplex in Ω_n is $(n-1)^2$ since Ω_n is, in the n^2 dimensional real vector space of all n by n matrices, a subset of a translate of an $(n-1)^2$ dimensional subspace D_n^*, the set of matrices with row and column sums equal to zero. M. Marcus and H. Minc [1] give an example of such an $(n-1)^2$ dimensional simplex. It seems natural to seek a maximal dimensional simplex whose vertices are also vertices of the polyhedron Ω_n. In this note we exhibit $(n-1)^2+1$ permutation matrices which are linearly independent, an even stronger property than that of being the vertices of an $(n-1)^2$-simplex.

We number the positions in a matrix of order m consecutively from 1 to m^2, referring to the position in row i and column j as the $[i+(j-i)m]$-th (mod m^2) position. This procedure assigns distinct numbers mod m^2 to distinct positions since if

$$i_1 + (j_1 - i_1)m \equiv i_2 + (j_2 - i_2)m \mod m^2$$

then $i_1 \equiv i_2 \mod m$, whence $i_1 = i_2$. Hence $j_1 m \equiv j_2 m \mod m^2$, implying $j_1 \equiv j_2 \mod m$. Consequently $j_1 = j_2$. If $m = 4$ the positions are numbered by

MORE HIGHLY COMPOSITE CONSECUTIVE INTEGERS

D. P. GIESY, University of Southern California

In [1] Subramanian and Becker show that for every n there are infinitely many sequences of n consecutive integers in which each integer contains a preassigned number of pairwise relatively prime factors, each factor to a preassigned power. I improve this result by noting that the (highly composite) factors of the consecutive integers can themselves be preassigned subject to certain limitations. In fact, the result is an immediate consequence of a well known Chinese remainder type

THEOREM. *The system* $x \equiv c_i \pmod{m_i}$ *for* $i = 1, \cdots, n$ *is solvable if and only if*

$$(m_i, m_j) \mid (c_i - c_j)$$

for $i, j = 1, \cdots, n$. *The solution, if it exists, is unique modulo the least common multiple of* $m_1, \cdots, m_n$.

(See [2] p. 34, Theorem 3–12.) The result follows by letting $c_i = -i$ in the theorem. Appropriate choices of the m_i's (for example, pairwise relatively prime) then furnish the required highly composite factors.

AN INFINITE CLASS OF HYPOHAMILTONIAN GRAPHS

W. F. LINDGREN, South Dakota School of Mines and Technology

We consider only finite, undirected, connected graphs. A circuit is called *simple* provided it has at most two edges incident with any given vertex. A simple circuit is a *hamiltonian circuit* (abbreviated *hc*) if it is incident with every vertex of the graph under consideration. A graph is *hypohamiltonian* (abbreviated *HH*) provided it has no hamiltonian circuit, but every subgraph obtained by deleting any one vertex and all edges incident with that vertex has such a circuit [1], [2]. We denote an edge between p_1 and p_2 by (p_1, p_2).

It has been shown that an *HH* graph of minimum order has 10 vertices, and further, that the solution is unique. We shall give a method for constructing an *HH* graph having an arbitrarily larger number of vertices.

Consider a regular polygon P with $6K+3$ vertices (K positive) numbered in counterclockwise order. Next add a point in the center of P and label it $c = 6K+4$. Now add all edges of the form $(c, 1+3j)$, where $j = 0, 1, \cdots, 2K$; these edges we shall call *spokes*. Next draw all edges of the form $(2+3j, 6+3j)$, $(j = 0, 1, 2, \cdots, 2K-1)$, and add $(c-2, 3)$. These edges we shall call *chords*.

There are the following types of edges: 1. $2K+1$ spokes, 2. $2(2K+1)$ edges

AN INFINITE CLASS OF HYPOHAMILTONIAN GRAPHS

W. F. LINDGREN, South Dakota School of Mines and Technology

We consider only finite, undirected, connected graphs. A circuit is called *simple* provided it has at most two edges incident with any given vertex. A simple circuit is a *hamiltonian circuit* (abbreviated *hc*) if it is incident with every vertex of the graph under consideration. A graph is *hypohamiltonian* (abbreviated *HH*) provided it has no hamiltonian circuit, but every subgraph obtained by deleting any one vertex and all edges incident with that vertex has such a circuit [1], [2]. We denote an edge between p_1 and p_2 by (p_1, p_2).

It has been shown that an *HH* graph of minimum order has 10 vertices, and further, that the solution is unique. We shall give a method for constructing an *HH* graph having an arbitrarily larger number of vertices.

Consider a regular polygon P with $6K+3$ vertices (K positive) numbered in counterclockwise order. Next add a point in the center of P and label it $c = 6K+4$. Now add all edges of the form $(c, 1+3j)$, where $j = 0, 1, \cdots, 2K$; these edges we shall call *spokes*. Next draw all edges of the form $(2+3j, 6+3j)$, $(j = 0, 1, 2, \cdots, 2K-1)$, and add $(c-2, 3)$. These edges we shall call *chords*.

There are the following types of edges: 1. $2K+1$ spokes, 2. $2(2K+1)$ edges

It remains to find an *hc* with each point deleted.

1. An *hc* with c deleted is P.

2. For $K>1$, an *hc* with 1 deleted is composed of the two spokes $(c, 7)$, $(c, 10)$; all chords except $(c-2, 3)$; and all edges of P except $(1, c-1)$, $(1, 2)$, $(5, 6)$, $(7, 8)$, $(9, 10)$, and the edges $(11+3j, 12+3j)$, $(j=0, 1, 2, \cdots, 2K-4)$. For $K=2$, an *hc* with 1 deleted meets the following vertices in order: 2, 3, 4, 5, 9, 8, 12, 13, 14, 15, 11, 10, 16, 7, 6, 2. For sufficiently large K, this circuit meets, in order: 2, 3, 4, 5, 9, 8, 12, 13, 14, 18, 19, 20, 24, 25, 26, 30, 31, 32, $\cdots$, $c-4$, $c-3$, $c-2$, $c-1$, $c-5$, $c-6$, $c-7$, $c-11$, $c-12$, $c-13$, $\cdots$, 11, 10, c, 7, 6, 2. For $K=1$, see [2].

3. An *hc* with 2 deleted is composed of the two spokes $(c, 1)$, $(c, c-3)$; the chord $(c-2, 3)$; and all edges of P except $(1, 2)$, $(2, 3)$, and $(c-2, c-3)$. We may obtain the other cases from symmetry.

ON PROJECTION OF MEASURE MATRICES

A. R. Amir-Moéz, Texas Technological College

In a three-dimensional Euclidean space, let $\mathfrak{A}$ be the area of a portion of a plane and $\mathfrak{B}$ be the area of the projection of that portion on another plane. Then $\mathfrak{B}=\mathfrak{A}|\cos\theta|$, where θ is the angle between the two planes. In this article we generalize the idea to the projection of an m-cell onto a subspace of R_n, a real unitary space.

1. Definitions and notations. The inner product of two vectors will be denoted by (ξ, η). The subspace spanned by vectors $\xi_1, \cdots, \xi_k$ will be denoted by $[\xi_1, \cdots, \xi_k]$. Let $\{\xi_1, \cdots, \xi_m\}$ be a linearly independent set of vectors in R_n. Suppose $\xi_i=x_{i1}\alpha_1+\cdots+x_{in}\alpha_n$, where $\{\alpha_1, \cdots, \alpha_n\}$ is an orthonormal basis in R_n. Then the matrix A, whose ith row is $(x_{i1}, \cdots, x_{in})$, $i=1, \cdots, m$, is called a measure matrix of the m-cell defined by $\xi_1, \cdots, \xi_m$. It is well known that the measure of this m-cell is

$$\mathfrak{A} = (1/m!)[\det AA']^{1/2},$$

where A' is the transpose of A and $\det AA'$ means the determinant of AA' [1], [2].

It is clear that the measure $\mathfrak{A}$ is independent of the choice of $\{\alpha_1, \cdots, \alpha_n\}$.

In what follows all projections are perpendicular or Hermitian.

2. Projection of an m-cell. Let $\{\alpha_1, \cdots, \alpha_n\}$ be an orthonormal basis for R_n. Choose an orthonormal set $\{\beta_2, \cdots, \beta_m\}$ such that $\beta_i \in [\alpha_i, \alpha_{i+2}]$,

It remains to find an *hc* with each point deleted.

1. An *hc* with c deleted is P.

2. For $K>1$, an *hc* with 1 deleted is composed of the two spokes $(c, 7)$, $(c, 10)$; all chords except $(c-2, 3)$; and all edges of P except $(1, c-1)$, $(1, 2)$, $(5, 6)$, $(7, 8)$, $(9, 10)$, and the edges $(11+3j, 12+3j)$, $(j=0, 1, 2, \cdots, 2K-4)$. For $K=2$, an *hc* with 1 deleted meets the following vertices in order: 2, 3, 4, 5, 9, 8, 12, 13, 14, 15, 11, 10, 16, 7, 6, 2. For sufficiently large K, this circuit meets, in order: 2, 3, 4, 5, 9, 8, 12, 13, 14, 18, 19, 20, 24, 25, 26, 30, 31, 32, $\cdots$, $c-4$, $c-3$, $c-2$, $c-1$, $c-5$, $c-6$, $c-7$, $c-11$, $c-12$, $c-13$, $\cdots$, 11, 10, c, 7, 6, 2. For $K=1$, see [2].

3. An *hc* with 2 deleted is composed of the two spokes $(c, 1)$, $(c, c-3)$; the chord $(c-2, 3)$; and all edges of P except $(1, 2)$, $(2, 3)$, and $(c-2, c-3)$. We may obtain the other cases from symmetry.

FINITELY GENERATED DOMAINS OVER JACOBSON SEMI-SIMPLE RINGS ARE JACOBSON SEMI-SIMPLE

J. A. EAGON, University of Illinois

The above statement, which does not seem to be in the literature, is a sort of "local Hilbert Nullstellensatz." Indeed, it follows that if P is a prime ideal in a commutative ring with unit R such that P is the intersection of maximal ideals, then any prime in $R[x]$ which contracts to P in R is the intersection of maximal ideals in $R[x]$. From this follows Theorem 3 in Goldman [1]. On the other hand the result here is more general since there are individual primes in quite arbitrary rings which are intersections of maximal ideals. Goldman proves the result for Hilbert rings, i.e., those rings where *every* prime is the intersection of maximal ideals. In this paper we also obtain one part of Theorem 5 in [1]. These are Goldman's main results, and other forms of the Nullstellensatz follow a la Goldman or directly. Proposition 1 is derived from Zariski ([2], Lemma 1) but the proof is short and included here.

PROPOSITION 1. *Let D be an integral domain and $D[t]$ a simply generated domain over it. Then, if t is algebraic with minimal polynomial g, leading coefficient a and M is a maximal ideal of D not containing a, or if t is transcendental and M is any maximal ideal of D, there exists a maximal ideal N of $D[t]$ such that $N \cap D = M$.*

Proof. We will show that $MD[t]$ is a proper ideal of $D[t]$ and then embed this ideal in a maximal ideal N which clearly has the required property. If $MD[t]$ is not proper then $1 = f(t)$ where $f(t)$ is a polynomial with coefficients in M. In the transcendental case this would imply that 1 is in M so we are done. In the algebraic case we divide g into f getting

$$a^n f(x) = g(x)q(x) + r(x), \qquad \deg r < \deg g, \text{ or } r = 0,$$

where the coefficients of q and r may be taken in the ideal generated by those of f, according to the well-known division algorithm. Thus we get

Here, cases in which $b_i = 0$ for some i have been omitted.

Therefore the measure of this ellipsoid is

$$\frac{(\sqrt{\pi})^m}{\Gamma((m/2)-1)}\, a^m \prod_{i=2}^{m} \frac{b_i}{a} = \frac{(\sqrt{\pi})^m}{\Gamma((m/2)-1)}\, a \prod_{i=2}^{m} b_i.$$

FINITELY GENERATED DOMAINS OVER JACOBSON SEMI-SIMPLE RINGS ARE JACOBSON SEMI-SIMPLE

J. A. EAGON, University of Illinois

The above statement, which does not seem to be in the literature, is a sort of "local Hilbert Nullstellensatz." Indeed, it follows that if P is a prime ideal in a commutative ring with unit R such that P is the intersection of maximal ideals, then any prime in $R[x]$ which contracts to P in R is the intersection of maximal ideals in $R[x]$. From this follows Theorem 3 in Goldman [1]. On the other hand the result here is more general since there are individual primes in quite arbitrary rings which are intersections of maximal ideals. Goldman proves the result for Hilbert rings, i.e., those rings where *every* prime is the intersection of maximal ideals. In this paper we also obtain one part of Theorem 5 in [1]. These are Goldman's main results, and other forms of the Nullstellensatz follow a la Goldman or directly. Proposition 1 is derived from Zariski ([2], Lemma 1) but the proof is short and included here.

PROPOSITION 1. *Let D be an integral domain and $D[t]$ a simply generated domain over it. Then, if t is algebraic with minimal polynomial g, leading coefficient a and M is a maximal ideal of D not containing a, or if t is transcendental and M is any maximal ideal of D, there exists a maximal ideal N of $D[t]$ such that $N \cap D = M$.*

Proof. We will show that $MD[t]$ is a proper ideal of $D[t]$ and then embed this ideal in a maximal ideal N which clearly has the required property. If $MD[t]$ is not proper then $1 = f(t)$ where $f(t)$ is a polynomial with coefficients in M. In the transcendental case this would imply that 1 is in M so we are done. In the algebraic case we divide g into f getting

$$a^n f(x) = g(x)q(x) + r(x), \qquad \deg r < \deg g, \text{ or } r = 0,$$

where the coefficients of q and r may be taken in the ideal generated by those of f, according to the well-known division algorithm. Thus we get

$$a^n = a^n f(t) = r(t).$$

Since $a^n - r(x)$ is a polynomial of degree less than g such that $a^n - r(t) = 0$ we have that $r(x) = a^n$ by the minimality of the degree of g. Thus a^n and hence a is in M, contradicting our hypothesis.

PROPOSITION 2. *If D is Jacobson semisimple then so is any simply generated domain over D.*

Proof. We observe that the intersection of all maximal ideals of D not containing a given nonzero element a is still zero. For, if x is in the intersection of such ideals then ax is in the intersection of all maximal ideals. Hence $ax = 0$ which implies $x = 0$.

Suppose $D[t]$ is not Jacobson semi-simple. Let $p(t)$ be a nonzero element in the Jacobson radical of $D[t]$. Then $1 + p(t)$ is a unit. In the transcendental case this implies the degree of $1 + p(t)$, and hence the degree of $p(t)$, is 0. In the algebraic case $p(t)$ is also algebraic over D, and the constant term of a minimal equation for $p(t)$ will be a nonzero element in the ideal generated by $p(t)$. Either way we have a nonzero element of D in the Jacobson radical of $D[t]$. But this element will be in every maximal ideal of D which is the contraction of a maximal ideal of $D[t]$. In the transcendental case this includes all maximal ideals, in the algebraic case all maximal ideals not containing a given element, by Proposition 1. Either way the intersection of these ideals is 0. This is a contradiction.

The remarks in the first paragraph give us

COROLLARY 1. *If R is a Hilbert ring so is $R[x]$.* ([1] Theorem 3.)

COROLLARY 2. *If D is Jacobson semi-simple and $D[t_1, \cdots, t_n]$ is a domain then the latter is also Jacobson semi-simple.*

Proof. Apply Proposition 2 inductively.

PROPOSITION 3. *If D is Jacobson semi-simple and if $D[t]$ is a field, then D is a field.*

Proof. Clearly, t must be algebraic, say with minimal polynomial g, leading coefficient a. By Proposition 1, every maximal ideal not containing a would be (0). If D were not a field then every maximal ideal would contain a, contradicting the hypothesis on D.

COROLLARY 2. *If R is a Hilbert ring then every maximal ideal in $R[x]$ contracts to a maximal ideal in R,* ([1], Theorem 5).

Proof. Apply Proposition 3.

The author wishes to thank Ed Davis for a helpful conversation.

A CONCISE PROOF OF BOREL'S THEOREM ON COEFFICIENT BOUNDS

R. A. WHITEMAN, IIT Research Institute

A classical theorem of Borel ([1], [2]) concerning the coefficient bounds of analytic functions with a positive real part defined on $|z|<1$ may be stated as:

Let $f(z)$ be an analytic function of a complex variable defined on $|z|<1$. If the real part of $f(z)$ is positive and the function is normalized to have the power series representation

$$f(z) = 1 + \sum c_n z^n, \tag{1}$$

then $|c_n| \leqq 2$ for $n=1, 2, \cdots$.

A concise generalized proof of this theorem may be achieved through F. Riesz's and Herglotz's Stieltjes integral representation of $f(z)$ [3]. The integral representation is

$$f(z) = \int_0^{2\pi} \frac{e^{it}+z}{e^{it}-z} \cdot d\phi(t) + iq, \tag{2}$$

where $\phi(t)$ is a bounded nondecreasing function of a real variable t such that $\phi(0)=0$ and $\phi(2\pi)>0$ and q is a real constant.

By expressing the integrand of (2) as a power series for $|z|<1$, and rearranging terms, the following power series for $f(z)$ is obtained;

$$f(z) = \int_0^{2\pi} d\phi(t) + \sum \left[2 \int_0^{2\pi} e^{-int} d\phi(t) \right] z^n + iq. \tag{3}$$

By comparing the power-series coefficients of (1) with those of (3), the following relations are obtained:

$$c_n = 2 \int_0^{2\pi} e^{-int} d\phi(t), \qquad \int_0^{2\pi} d\phi(t) = 1 \text{ and } q = 0.$$

Since $\phi(t)$ is a nondecreasing function, $|c_n| \leqq 2\int_0^{2\pi} |d\phi(t)| = 2\int_0^{2\pi} d\phi(t)$ and therefore, $|c_n| \leqq 2$, for $n=1, 2, \cdots$.

A CONCISE PROOF OF BOREL'S THEOREM ON COEFFICIENT BOUNDS

R. A. WHITEMAN, IIT Research Institute

A classical theorem of Borel ([1], [2]) concerning the coefficient bounds of analytic functions with a positive real part defined on $|z|<1$ may be stated as:

Let $f(z)$ be an analytic function of a complex variable defined on $|z|<1$. If the real part of $f(z)$ is positive and the function is normalized to have the power series representation

$$f(z) = 1 + \sum c_n z^n, \tag{1}$$

then $|c_n| \leqq 2$ for $n=1, 2, \cdots$.

A concise generalized proof of this theorem may be achieved through F. Riesz's and Herglotz's Stieltjes integral representation of $f(z)$ [3]. The integral representation is

$$f(z) = \int_0^{2\pi} \frac{e^{it}+z}{e^{it}-z} \cdot d\phi(t) + iq, \tag{2}$$

where $\phi(t)$ is a bounded nondecreasing function of a real variable t such that $\phi(0)=0$ and $\phi(2\pi)>0$ and q is a real constant.

By expressing the integrand of (2) as a power series for $|z|<1$, and rearranging terms, the following power series for $f(z)$ is obtained;

$$f(z) = \int_0^{2\pi} d\phi(t) + \sum \left[2 \int_0^{2\pi} e^{-int} d\phi(t) \right] z^n + iq. \tag{3}$$

By comparing the power-series coefficients of (1) with those of (3), the following relations are obtained:

$$c_n = 2 \int_0^{2\pi} e^{-int} d\phi(t), \qquad \int_0^{2\pi} d\phi(t) = 1 \text{ and } q = 0.$$

Since $\phi(t)$ is a nondecreasing function, $|c_n| \leqq 2\int_0^{2\pi} |d\phi(t)| = 2\int_0^{2\pi} d\phi(t)$ and therefore, $|c_n| \leqq 2$, for $n=1, 2, \cdots$.

FUNCTIONS AND INVERSES OF ASYMPTOTIC FUNCTIONS

R. C. ENTRINGER, University of New Mexico

In this note we consider the following two problems: (1) *Given* $f(x)\to\infty$ *and* $f(x)\sim g(x)$ *as* $x\to\infty$, *for what functions* $h(x)$ *is* $h(f(x))\sim h(g(x))$? (2) *For what functions* $f(x)$ *does* $f(x)\sim g(x)$ *imply* $f^{-1}(x)\sim g^{-1}(x)$ *as* $x\to\infty$? (Here and throughout this note the -1 superscript will denote the inverse function.)

In problem (1) we note that if $h(x)=x^r$ where r is any real number then $h(f(x))\sim h(g(x))$, but if $h(x)=e^x$, $f(x)=x$, $g(x)=x+1$, then $h(f(x))\nsim h(g(x))$. For a more interesting example the reader may consult [1] where it is shown that $\prod_{p\leq x} p\sim e^x$ even though $\sum_{p\leq x}\log p\sim x$ (p prime).

In problem (2) we see that if $f(x)=\log x$, $g(x)=\log 2x$ then $f(x)\sim g(x)$, but $f^{-1}(x)=e^x\nsim\frac{1}{2}e^x=g^{-1}(x)$. On the other hand (employing the usual number-theoretic notation) $\pi(n)\sim n/\log n$ and

$$(\pi(n))^{-1}=p_n\sim n\log n\sim(n/\log n)^{-1}.$$

In Theorems 1 and 2 we obtain restrictions on the size of $h(x)$ and $f(x)$ so that the conclusions of the problems obtain. We also show that these restrictions cannot be relaxed to any great extent.

THEOREM 1. (i) *If* $f(x)\to\infty$ *and* $f(x)\sim g(x)$ *as* $x\to\infty$, *and if* $h(x)$ *is monotonic and* $h'(x)/h(x)=O(1/x)$ *for all sufficiently large* x, *then* $h(f(x))\sim h(g(x))$ *as* $x\to\infty$.

(ii) *If* $h'(x)$ *is strictly monotonic for all sufficiently large* x *and* $h(x)/h'(x)=o(x)$ *as* $x\to\infty$ *then there are functions* $f(x)$ *and* $g(x)$ *such that* $f(x)\to\infty$, $f(x)\sim g(x)$ *and* $h(f(x))\nsim h(g(x))$ *as* $x\to\infty$.

Proof. (i) Let $M(x)=\max(f(x), g(x))$ and $m(x)=\min(f(x), g(x))$. Then, by the mean value theorem there is a c, $m(x)\leqq c\leqq M(x)$ for which

$$|h(f(x))-h(g(x))| = |h'(c)\{f(x)-g(x)\}| = |h(c)O(1/c)o(M(x))|$$
$$\leqq |\max\{h(M(x)), h(m(x))\}O(1/m(x))o(M(x))| = o(\max\{h(M(x)), h(m(x))\})$$

as $x\to\infty$. This completes the proof of (i) since $\max\{h(M(x)), h(m(x))\}$ is $h(f(x))$ or $h(g(x))$.

(ii) We first consider the case where $h'(x)$ is strictly increasing. For all sufficiently large x, $h'(x)\neq 0$ and if we set

$$f(x)=x,\quad g(x)=x+\frac{|h(x)|}{h'(x)}$$

we have $f(x)\to\infty$ and $f(x)\sim g(x)$ as $x\to\infty$. Now for some c between x and $x+(|h(x)|/h'(x)$, we have

$$|h(f(x))-h(g(x))| = \left|h'(c)\frac{h(x)}{h'(x)}\right| \geqq |h'(x)|\left|\frac{h(x)}{h'(x)}\right| \neq o(h(x))$$

and hence $h(f(x))\nsim h(g(x))$. If $h'(x)$ is strictly decreasing we set

$$g(x) \sim \sqrt{2\pi}\,\frac{x^{x+1/2}}{e^x} \quad \text{and} \quad h(x) \sim \frac{\log x}{\log\log x},$$

then $h(\sqrt{2\pi}(x^{x+1/2}/e^x)) \sim x$ as $x \to \infty$. Hence $g^{-1}(x) \sim \log x/\log\log x$.

SEMIGROUPS WHOSE REGULAR REPRESENTATION IS A RIGHT GROUP

J. L. CHRISLOCK, University of California, Santa Cruz

1. Introduction. As in [3], if S is a semigroup we denote by ρ_x the mapping $a\,\rho_x = ax$, but, for convenience, we will call the semigroup $\{\rho_x : x \in S\}$ the regular representation of S.

Given a transformation semigroup T on a set S it is natural to ask whether or not there exists a binary operation on S making S a semigroup with T as its regular representation. The general problem seems too difficult, but if we restrict T to the class of right groups we will see in Theorem 2 that (C) is necessary and sufficient for such an operation to exist.

To prove this fact we determine in Theorem 1 all semigroups whose regular representation is a right group, and it turns out that these are exactly the M-inversive semigroups introduced by Yamada [5].

2. M-inversive semigroups. A right group is a semigroup with a left identity and with right solvability. The following lemma is proved in [3, p. 38; 2; 4].

LEMMA 1. *A semigroup is a right group if and only if it is the direct product $G \times R$ of a group G and a right zero semigroup R.*

Yamada [5] defines an M-inversive semigroup to be one in which for all $a \in S$ there exist $x, y \in S$ such that

$$(1) \qquad caxd = cd, \qquad (2) \qquad cyad = cd,$$

for all $c, d \in S$. We now give a necessary definition [3] and then Yamada's characterization, Lemma 2, of these semigroups.

DEFINITION. *Let S be a semigroup. For each $x \in S$, let A_x be a set containing x such that the sets A_x, $x \in S$, are pairwise disjoint. If $S' = \bigcup\{A_x : x \in S\}$ and if $a \cdot b = xy$, where $a \in A_x$ and $b \in A_y$, then $(S', \cdot)$ is called an inflation of S.*

LEMMA 2. *S is M-inversive if and only if it is an inflation of a direct product $G \times L \times R$ of a group G, a left zero semigroup L, and a right zero semigroup R.*

If on a semigroup we define a mapping λ_a by $x\lambda_a = ax$, then we will call the

$$g(x) \sim \sqrt{2\pi}\,\frac{x^{x+1/2}}{e^x} \quad \text{and} \quad h(x) \sim \frac{\log x}{\log\log x},$$

then $h(\sqrt{2\pi}(x^{x+1/2}/e^x)) \sim x$ as $x \to \infty$. Hence $g^{-1}(x) \sim \log x/\log\log x$.

SEMIGROUPS WHOSE REGULAR REPRESENTATION IS A RIGHT GROUP

J. L. CHRISLOCK, University of California, Santa Cruz

1. Introduction. As in [3], if S is a semigroup we denote by ρ_x the mapping $a\,\rho_x = ax$, but, for convenience, we will call the semigroup $\{\rho_x : x \in S\}$ the regular representation of S.

Given a transformation semigroup T on a set S it is natural to ask whether or not there exists a binary operation on S making S a semigroup with T as its regular representation. The general problem seems too difficult, but if we restrict T to the class of right groups we will see in Theorem 2 that (C) is necessary and sufficient for such an operation to exist.

To prove this fact we determine in Theorem 1 all semigroups whose regular representation is a right group, and it turns out that these are exactly the M-inversive semigroups introduced by Yamada [5].

2. M-inversive semigroups. A right group is a semigroup with a left identity and with right solvability. The following lemma is proved in [3, p. 38; 2; 4].

LEMMA 1. *A semigroup is a right group if and only if it is the direct product $G \times R$ of a group G and a right zero semigroup R.*

Yamada [5] defines an M-inversive semigroup to be one in which for all $a \in S$ there exist $x, y \in S$ such that

$$(1) \qquad caxd = cd, \qquad (2) \qquad cyad = cd,$$

for all $c, d \in S$. We now give a necessary definition [3] and then Yamada's characterization, Lemma 2, of these semigroups.

DEFINITION. *Let S be a semigroup. For each $x \in S$, let A_x be a set containing x such that the sets A_x, $x \in S$, are pairwise disjoint. If $S' = \bigcup\{A_x : x \in S\}$ and if $a \cdot b = xy$, where $a \in A_x$ and $b \in A_y$, then $(S', \cdot)$ is called an inflation of S.*

LEMMA 2. *S is M-inversive if and only if it is an inflation of a direct product $G \times L \times R$ of a group G, a left zero semigroup L, and a right zero semigroup R.*

If on a semigroup we define a mapping λ_a by $x\lambda_a = ax$, then we will call the

semigroup of all such mappings the regular anti-representation of S. In the following we will give only proofs for the regular representation of S, but the proofs for the regular antirepresentation are identical.

Using Lemma 2, we can now characterize the M-inversive semigroups by their regular [anti-] representation.

THEOREM 1. *S is M-inversive if and only if its regular [anti-] representation is a right group.*

Proof. Assume that S is M-inversive. The definition of M-inversive is equivalent to the following: for all $a \in S$ there exist x, $y \in S$ such that

$$(1') \qquad \rho_a \rho_x \rho_d = \rho_d, \qquad (2') \qquad \rho_y \rho_a \rho_d = \rho_d,$$

for all $d \in S$. From (1') and (2') it follows trivially that the regular representation T is M-inversive with a left identity. The fact that T has a left identity implies that $T^2 = T$, which in turn implies from the definition that the inflation in Lemma 2 is trivial. Hence, $T \cong G \times L \times R$ for some G, L, and R. Let $(e, a, b) \in G \times L \times R$ be a left identity, where e is the identity of G. For arbitrary $(x, c, d) \in G \times L \times R$,

$$(x, c, d) = (e, a, b)(x, c, d) = (x, a, d).$$

We conclude that $a = c$ and that $|L| = 1$, which implies that $T \cong G \times R$ or that T is a right group.

COROLLARY. *The regular [anti-] representation T of a semigroup S is a group if and only if S is an inflation of a left [right] group $G \times L$ [$G \times R$].*

Proof. Assume that T is a group. Theorem 1 tells us that S is an inflation of a direct product $G \times L \times R$. Also, since T is a group, there exists an element $e \in S$ such that

$$(3) \qquad \rho_x \rho_e = \rho_x, \quad \text{for all } x \in S.$$

We can assume that $e \in G \times L \times R$. Let $e = (f, x, y)$ and let (g, a, b) and (h, c, d) be arbitrary members of $G \times L \times R$. It follows from (3) that f must be the identity of G and that

$$(gh, a, y) = (g, a, b)(h, c, d)(f, x, y) = (g, a, b)(h, c, d) = (gh, a, d).$$

This proves that $y = d$, and since (h, c, d) was arbitrary, $|R| = 1$. Hence, S is an inflation of a left group.

Conversely, if S is an inflation of a left group, we can easily show (3), which along with Theorem 1 proves that the regular representation of S is a group.

3. The main theorem.

THEOREM 2. *If T is a right group of transformations on a set S, then there exists a binary operation on S such that S is a semigroup with T as its regular [anti-] representation if and only if, for all $x \in S$ and all $\alpha, \beta \in T$,*

(C) *$x\alpha = x\beta$ implies $\alpha = \beta$.*

Proof. Let E be the set of idempotents of S indexed by the set I. We will call any congruence relation η on S which satisfies $e_\alpha x \eta x$, for all $x \in S$ and for all $\alpha \in I$, an i-congruence on S. Now define the congruence σ by $a\sigma b$ if $\rho_a = \rho_b$. If $a\sigma b$ then $e_\alpha \rho_a = e_\alpha \rho_b$ or $e_\alpha a = e_\alpha b$, for all $\alpha \in I$. Let η be any i-congruence on S. Then $a\eta e_\alpha a = e_\alpha b \eta b$. Hence $a\eta b$, and $\sigma \subseteq \eta$. Now any group-congruence on S is also an i-congruence on S. It follows that σ is the smallest group-congruence on S. Further, $S/\sigma \cong T$.

The author would like to thank Professor Takayuki Tamura for directing this research and the referee who offered many helpful remarks, and suggested the use of the antiregular representation.

Weaker results were published under a different title as a brief note in [1] and were presented to the Society, August 25, 1964. Although the method is changed, the earlier results appear here.

ON MÖBIUS' FUNCTION AND RELATED MATTERS

A. A. MULLIN, University of California, Livermore (Now at Aberdeen Proving Ground, Maryland)

1. Introduction. This note relates Möbius' number-theoretic function [1] to its analogue relative to the author's "mosaic model" of elementary unique factorization [2]. By "mosaic model" of elementary unique factorization is meant the 1-1 mapping of the natural numbers to "configurations" of prime numbers alone obtained by applying recursively the canonic prime-power factorization of natural numbers to its own exponents. For a given natural number the "configuration" of primes is called a *mosaic*. For example, (1) the mosaic of 192 is $2^{2\cdot 3}\cdot 3$; and (2) the mosaic of a square-free number coincides with its canonic prime decomposition, although this can be the case with nonsquare-free numbers such as 666. This self-recursion technique is quite old, as one may use it to obtain the Euclidean algorithm from the division algorithm. Further, conjectures are given in [4] bearing on the prime number theorem [3] and the ordinary Riemann hypothesis for the ordinary zeta-function.

2. Definitions and propositions. Define μ^* (*Modified Möbius Function*) as follows: $\mu^*(1) = 1$; $\mu^*(n) = 0$, if the mosaic of $n > 1$ has any prime number repeated; and $\mu^*(n) = (-1)^m$ if the mosaic of $n > 1$ has no prime repeated, where m is the number of (distinct) primes in the mosaic of n.

By analogy with the multiplicativity of μ one has, clearly,

Proof. Let E be the set of idempotents of S indexed by the set I. We will call any congruence relation η on S which satisfies $e_\alpha x \eta x$, for all $x \in S$ and for all $\alpha \in I$, an i-congruence on S. Now define the congruence σ by $a\sigma b$ if $\rho_a = \rho_b$. If $a\sigma b$ then $e_\alpha \rho_a = e_\alpha \rho_b$ or $e_\alpha a = e_\alpha b$, for all $\alpha \in I$. Let η be any i-congruence on S. Then $a\eta e_\alpha a = e_\alpha b \eta b$. Hence $a\eta b$, and $\sigma \subseteq \eta$. Now any group-congruence on S is also an i-congruence on S. It follows that σ is the smallest group-congruence on S. Further, $S/\sigma \cong T$.

The author would like to thank Professor Takayuki Tamura for directing this research and the referee who offered many helpful remarks, and suggested the use of the antiregular representation.

Weaker results were published under a different title as a brief note in [1] and were presented to the Society, August 25, 1964. Although the method is changed, the earlier results appear here.

ON MÖBIUS' FUNCTION AND RELATED MATTERS

A. A. MULLIN, University of California, Livermore (Now at Aberdeen Proving Ground, Maryland)

1. Introduction. This note relates Möbius' number-theoretic function [1] to its analogue relative to the author's "mosaic model" of elementary unique factorization [2]. By "mosaic model" of elementary unique factorization is meant the 1-1 mapping of the natural numbers to "configurations" of prime numbers alone obtained by applying recursively the canonic prime-power factorization of natural numbers to its own exponents. For a given natural number the "configuration" of primes is called a *mosaic*. For example, (1) the mosaic of 192 is $2^{2\cdot 3}\cdot 3$; and (2) the mosaic of a square-free number coincides with its canonic prime decomposition, although this can be the case with nonsquare-free numbers such as 666. This self-recursion technique is quite old, as one may use it to obtain the Euclidean algorithm from the division algorithm. Further, conjectures are given in [4] bearing on the prime number theorem [3] and the ordinary Riemann hypothesis for the ordinary zeta-function.

2. Definitions and propositions. Define μ^* (*Modified Möbius Function*) as follows: $\mu^*(1) = 1$; $\mu^*(n) = 0$, if the mosaic of $n > 1$ has any prime number repeated; and $\mu^*(n) = (-1)^m$ if the mosaic of $n > 1$ has no prime repeated, where m is the number of (distinct) primes in the mosaic of n.

By analogy with the multiplicativity of μ one has, clearly,

C1. $\sum_{m \leq x} \mu^*(m) = o(x)$ entails the prime number theorem and

C2. $\sum_{m \leq x} \mu^*(m) = O(x^{1/2})$ entails the ordinary Riemann hypothesis for the ordinary zeta-function.

If C1 or C2 is, indeed, valid, how can either be weakened so that full equivalence with the prime number theorem or the Riemann hypothesis can be obtained? Finally it might be interesting to study the author's *Modified Liouville Function* [6] of exponential number-theory from the point of view of its possible relations to the Prime Number Theorem and the Riemann Hypothesis, and its known relations with the standard Liouville and Möbius functions [9].

This research was conducted under the auspices of the U. S. Atomic Energy Commission and the U. S. Department of Army.

ON THE ROOTS OF THE DERIVATIVE OF A POLYNOMIAL WITH REAL ROOTS

GIDEON PEYSER, Newark College of Engineering

In this note we investigate the location of the roots of the derivative of a polynomial with all real roots. The location of these roots is of interest in analysis, in particular in investigations of hyperbolic partial differential equations, whose main property is that the characteristic polynomial has only real roots.

From elementary considerations it follows that if a polynomial has only real roots, then between two adjacent (not necessarily simple) distinct roots lies a unique simple root of the derivative. This note is concerned with the location of these roots relative to the roots of the original polynomial.

All polynomials will be written in increasing order of their roots. In particular, throughout the paper we denote

$$P(x) = (x - a_1) \cdots (x - a_n) \qquad a_i \text{ real}, \quad a_i \leqq a_{i+1} \tag{1}$$

$$P'(x) = (x - c_1) \cdots (x - c_{n-1}) \qquad a_i \leqq c_i \leqq a_{i+1}. \tag{2}$$

The main result is the following:

C1. $\sum_{m \leq x} \mu^*(m) = o(x)$ entails the prime number theorem and

C2. $\sum_{m \leq x} \mu^*(m) = O(x^{1/2})$ entails the ordinary Riemann hypothesis for the ordinary zeta-function.

If C1 or C2 is, indeed, valid, how can either be weakened so that full equivalence with the prime number theorem or the Riemann hypothesis can be obtained? Finally it might be interesting to study the author's *Modified Liouville Function* [6] of exponential number-theory from the point of view of its possible relations to the Prime Number Theorem and the Riemann Hypothesis, and its known relations with the standard Liouville and Möbius functions [9].

This research was conducted under the auspices of the U. S. Atomic Energy Commission and the U. S. Department of Army.

ON THE ROOTS OF THE DERIVATIVE OF A POLYNOMIAL WITH REAL ROOTS

GIDEON PEYSER, Newark College of Engineering

In this note we investigate the location of the roots of the derivative of a polynomial with all real roots. The location of these roots is of interest in analysis, in particular in investigations of hyperbolic partial differential equations, whose main property is that the characteristic polynomial has only real roots.

From elementary considerations it follows that if a polynomial has only real roots, then between two adjacent (not necessarily simple) distinct roots lies a unique simple root of the derivative. This note is concerned with the location of these roots relative to the roots of the original polynomial.

All polynomials will be written in increasing order of their roots. In particular, throughout the paper we denote

$$P(x) = (x - a_1) \cdots (x - a_n) \qquad a_i \text{ real}, \quad a_i \leqq a_{i+1} \tag{1}$$

$$P'(x) = (x - c_1) \cdots (x - c_{n-1}) \qquad a_i \leqq c_i \leqq a_{i+1}. \tag{2}$$

The main result is the following:

LEMMA 4. *Let* $T(x)=(x-a_1)\cdots(x-a_{n-1})(x-a_n+\epsilon)$, *where* $\epsilon\geqq 0$ *is such that* $a_n-\epsilon\geqq a_2$ *and let* $T'(x)=(n-1)(x-g_1)\cdots(x-g_{n-2})$ *then* $g_1\leqq c_1$.

We now can prove the main theorem. We consider the polynomial $W(x)=(x-a_k)^k(x-a_{k+1})$. $W'(x)$ has a root

$$c=\frac{ka_{k+1}+a_k}{k+1}=a_{k+1}-\frac{a_{k+1}-a_k}{k+1}.$$

From repeated application of Lemmas 1 and 3 it follows that

$$c_k\leqq c=a_{k+1}-\frac{a_{k+1}-a_k}{k+1}.$$

Similarly it follows from the consideration of the polynomial $(x-a_k)(x-a_{k+1})^{n-k}$ and Lemmas 2 and 4 that

$$c_k\geqq a_k+\frac{a_{k+1}-a_k}{n+1-k}.$$

This completes the proof.

From (3) we have the following

COROLLARY. *The root* c_k *of* $P'(x)$, $1\leqq k\leqq n-1$, *satisfies the inequality*

$$a_k+\frac{a_{k+1}-a_k}{n}\leqq c_k\leqq a_{k+1}-\frac{a_{k+1}-a_k}{n}. \tag{7}$$

This means that the root c_k cannot be closer to either a_k or a_{k+1} than $1/n$ of the distance between a_k and a_{k+1}. This estimate is independent of the index k and depends only on the degree n of $P(x)$.

As another application of (3) we note that c_1 is always in the first half of the first interval, i.e., $c_1\leqq(a_1+a_2)/2$ and c_{n-1} is always in the second half of the last interval, $c_{n-1}\geqq(a_n+a_{n-1})/2$.

ON BURCHNALL'S GENERATING RELATION FOR BESSEL POLYNOMIALS

J. W. BROWN, Oberlin College

1. Since 1949 there has been considerable interest in what Krall and Frink [4] have called the Bessel polynomials:

$$y_n(x,a,b)={}_2F_0(-n,a-1+n;-x/b). \tag{1}$$

While Krall and Frink were the first to study these polynomials for their own sake, various subsequent authors have concentrated on direct connections between these and certain of the more familiar classical polynomials. For instance, Agarwal [1] noted that the Bessel polynomials are special limiting cases of the

LEMMA 4. *Let* $T(x)=(x-a_1)\cdots(x-a_{n-1})(x-a_n+\epsilon)$, *where* $\epsilon\geqq 0$ *is such that* $a_n-\epsilon\geqq a_2$ *and let* $T'(x)=(n-1)(x-g_1)\cdots(x-g_{n-2})$ *then* $g_1\leqq c_1$.

We now can prove the main theorem. We consider the polynomial $W(x)=(x-a_k)^k(x-a_{k+1})$. $W'(x)$ has a root

$$c=\frac{ka_{k+1}+a_k}{k+1}=a_{k+1}-\frac{a_{k+1}-a_k}{k+1}.$$

From repeated application of Lemmas 1 and 3 it follows that

$$c_k\leqq c=a_{k+1}-\frac{a_{k+1}-a_k}{k+1}.$$

Similarly it follows from the consideration of the polynomial $(x-a_k)(x-a_{k+1})^{n-k}$ and Lemmas 2 and 4 that

$$c_k\geqq a_k+\frac{a_{k+1}-a_k}{n+1-k}.$$

This completes the proof.

From (3) we have the following

COROLLARY. *The root* c_k *of* $P'(x)$, $1\leqq k\leqq n-1$, *satisfies the inequality*

$$a_k+\frac{a_{k+1}-a_k}{n}\leqq c_k\leqq a_{k+1}-\frac{a_{k+1}-a_k}{n}. \tag{7}$$

This means that the root c_k cannot be closer to either a_k or a_{k+1} than $1/n$ of the distance between a_k and a_{k+1}. This estimate is independent of the index k and depends only on the degree n of $P(x)$.

As another application of (3) we note that c_1 is always in the first half of the first interval, i.e., $c_1\leqq(a_1+a_2)/2$ and c_{n-1} is always in the second half of the last interval, $c_{n-1}\geqq(a_n+a_{n-1})/2$.

ON BURCHNALL'S GENERATING RELATION FOR BESSEL POLYNOMIALS

J. W. BROWN, Oberlin College

1. Since 1949 there has been considerable interest in what Krall and Frink [4] have called the Bessel polynomials:

$$y_n(x,a,b)={}_2F_0(-n,a-1+n;-x/b). \tag{1}$$

While Krall and Frink were the first to study these polynomials for their own sake, various subsequent authors have concentrated on direct connections between these and certain of the more familiar classical polynomials. For instance, Agarwal [1] noted that the Bessel polynomials are special limiting cases of the

Jacobi polynomials and showed how various properties of the former are inherited from the latter. Indeed, he obtained from a well-known generating relation for the Jacobi polynomials Burchnall's formula [3]

$$(2)\quad \sum_{n=0}^{\infty} y_n(x, a, 1)t^n/n! = \frac{1}{\sqrt{(1-4xt)}}\left(\frac{2}{1+\sqrt{(1-4xt)}}\right)^{a-2}\exp\left(\frac{2t}{1+\sqrt{(1-4xt)}}\right)$$

which is the earliest known generating relation for Bessel polynomials with the parameter a arbitrary. As Burchnall pointed out, the parameter b in (1) is merely a scaling factor and may be taken as unity without loss of generality.

More recently, Al-Salam [2] observed that the Bessel polynomials are essentially Laguerre polynomials with the parameter of the latter varying with the index. That is,

$$(3)\quad y_n^*(x, a, 1)/n! = (-1)^n L_n^{1-a-2n}(x),$$

where it is understood that $p_n^*(x)$ denotes the *reverse* $x^n p_n(1/x)$ of a given polynomial $p_n(x)$. Al-Salam pointed out that with (3) it is a simple matter to rewrite various known properties of the Laguerre polynomials in terms of Bessel polynomials. While his viewpoint thus paralleled Agarwal's, he did not include a corresponding derivation of (2). Our purpose here is to furnish such a derivation.

2. From the familiar generating relation [5]

$$(4)\quad \sum_{n=0}^{\infty} L_n^a(x)t^n = (1-t)^{-a-1}\exp\left(\frac{xt}{t-1}\right)$$

we derive

$$(5)\quad \sum_{n=0}^{\infty} (-1)^n L_n^{1-a-2n}(x)t^n = \frac{1}{\sqrt{(1-4t)}}\left(\frac{2}{1+\sqrt{(1-4t)}}\right)^{a-2}\exp\left(\frac{2xt}{1+\sqrt{(1-4t)}}\right)$$

which, by (3), is the equivalent form of (2) in the language of Laguerre polynomials. Concentrating on the way in which the parameter enters into the right-hand side of (4), we find it convenient to present our derivation in the context of more general polynomials $f_n^a(x)$ generated by a relation of the form

$$(6)\quad \sum_{n=0}^{\infty} f_n^a(x)t^n = (1-t)^{-a-1}F(x, t),$$

where $F(x, t)$ is independent of the parameter a. Keeping in mind that $f_n^a(x) = L_n^a(x)$ when $F(x, t) = \exp(xt/(t-1))$, we find that this more general setting furnishes a deeper insight into the nature of the connection between (4) and (5).

THEOREM. *If there is a generating relation of the form* (6) *for given polynomials* $f_n^a(x)$, *then*

$$(7)\quad \sum_{n=0}^{\infty} (-1)^n f_n^{1-a-2n}(x)t^n = \frac{1}{\sqrt{(1-4t)}}\left(\frac{2}{1+\sqrt{(1-4t)}}\right)^{a-2}F\left(x, \frac{-4t}{[1+\sqrt{(1-4t)}]^2}\right).$$

The author is indebted to the late Professor E. D. Rainville, of the University of Michigan, for his help and encouragement.

ON A REMARK OF UTZ

FRED GROSS, Bellcomm, Inc., Washington

W. R. Utz in introducing the problem "The equation $f'(x)=af(g(x))$" (Bull. Amer. Math. Soc. Vol. 71, No. 694, Jan. 1965) commented that the corresponding problem for certain special cases is fairly simple for analytic functions.

I think it is worth mentioning that for entire functions the problem can be completely solved. We shall use the following theorem of Polya [1]:

For two entire functions f and g such that $g(0)=0$ one has $M_{f\circ g}(r)\geqq M_f(cM_g(r/2))$, where $M_h(r)=\max_{|z|=r}|h(z)|$ and c is an appropriate positive constant.

We now prove:

THEOREM 1. *If $f(z)$ is entire and not identically zero, then the only entire solutions $g(z)$ of the equation $f'(z)=af(g(z))$ are linear, where a is any complex number.*

Proof. Let us first assume that $g(0)=0$. In this case

$$M_{f'}(r) = |a| M_{f\circ g}(r) \geqq |a| M_f(cM_g(r/2)) \geqq |a| M_{f'}(c'M_g(r/2))(c-c')M_g(r/2)$$
$$\geqq M_{f'}(c'M_g(r/2))$$

for sufficiently large r provided that g is not a constant, where $0<c'<c$. The second inequality relating f to f' follows from the inequality

$$M_{f'}(r) \leqq \frac{M_f(R)}{R-r}, \quad \text{where} \quad R>r.$$

See Titchmarsh [2].

Since $M_{f'}$ is monotonic increasing [3] it follows that $c'M_g(r/2)\leqq r$ and consequently that g must be linear.

When $g(0)\neq 0$ let $\bar{g}(z)=g(z)-g(0)$ and $\bar{f}(u)=f(u+g(0))$, then $f(g)=\bar{f}(\bar{g})$. Using an argument similar to the one above we get

$$M_{f'}(r) \geqq M_{\bar{f}'}(c'M_{\bar{g}}(r/2)) \geqq M_{f'}(c'M_{\bar{g}}(r/2) - |g(0)|),$$

which as before leads to the conclusion that $\bar{g}$ and hence g must be linear.

Utz gave the example $f(x)=A(\sin ax+\cos ax)$. This function is entire and satisfies $f'(x)=af(-x)$. One can easily verify that for any $|A|\leqq 1$, $A\neq 1$ and any constant B there exists an entire $f(z)$ such that $f'(z)=f(Az+B)$.

For example the function

$$f(z)=\sum_{n=0}^{\infty}\frac{A^{n(n-1)/2}z^n}{n!}$$

is entire for $|A|\leqq 1$ and one can easily verify that $f'(z)=f(Az)$.

Thus, for $D=-B/(A-1)$ and $f_1(z+D)=f(z)$, $f_1(A(z+D)+B)=f_1'(z+D)$ or letting $z+D=z'$, $f_1(Az'+B)=f_1'(z')$.

Note that similar solutions can be found for $f'(z)=af(Az+B)$, where a is a constant and $|A|\leqq 1$.

The identical argument can also be used to show more generally that, for any $f^{(n)}(z)n=0, 1, 2, \cdots$, where $f^{(0)}=f$, we have

THEOREM 2. *If $f(z)$ is entire, then the only entire solutions $g(z)$ of the equation $f^{(n)}(z)=af(g(z))$ are linear.*

A CONJECTURE ON THE EXTENSION OF BILINEAR FUNCTIONALS

T. L. HAYDEN, University of Kentucky

In analogy with the Hahn-Banach Theorem the following conjecture seems plausible:

CONJECTURE. *Suppose each of U and V is a linear space and that p and q are subadditive, positively homogeneous functions on U and V respectively. Then if S and T are subspaces of U and V respectively and $f(s, t)$ is a bilinear functional defined on $S\times T$ such that $f(s, t)\leqq p(s)q(t)$, there is a bilinear functional F on $U\times V$ such that $F(s, t)=f(s, t)$ on $S\times T$ and $F(u, v)\leqq p(u)q(v)$ on $U\times V$.*

We show that the conjecture is true for Hilbert spaces.

THEOREM. *Suppose $S_1, S_2, \cdots, S_n$ are subspaces respectively of the complex Hilbert spaces $X_1, X_2, \cdots, X_n$ and $f(s_1, s_2, \cdots, s_n)$ is a multilinear functional defined on $\times_{k=1}^{n}S_k$ with norm K. Then there exists a multilinear functional F on $\times_{k=1}^{n}X_k$ with norm K such that F is f on $\times_{k=1}^{n}S_k$.*

Proof. First we show that f can be extended to a function defined on

$\times_{k=1}^{n}(S_k \cup \{x_k\})$ for $x_k \notin S_k$, $k=1, 2, \cdots, n$. In fact, take $x_k \perp S_k$, and define $h(a_1x_1+s_1, \cdots, a_nx_n+s_n) = K\prod_{k=1}^{n} a_k\|x_k\| + f(s_1, \cdots, s_n)$ where $a_1, a_2, \cdots, a_n$ are scalars and K is the norm of f. It is immediate that the extension is multilinear, and we now show that the norm is the same.

$$|h(a_1x_1 + s_1, \cdots, a_nx_n + s_n)| \leqq K\left(\prod_{k=1}^{n}\|a_kx_k\| + \prod_{k=1}^{n}\|s_k\|\right)$$

$$\leqq K\prod_{k=1}^{n}\left(\|a_kx_k\|^{u_k} + \|s_k\|^{u_k}\right)^{1/u_k} \tag{1}$$

$$\leqq K\prod_{k=1}^{n}\left(\|a_kx_k\|^2 + \|s_k\|^2\right)^{1/2} = K\prod_{k=1}^{n}\|a_kx_k + s_k\|, \tag{2}$$

where $u_k \geqq 2$ and $1 \geqq \sum_{k=1}^{n} u_k^{-1}$. In (1) we have used a generalization of Hölder's inequality [1, 20], while (2) follows from an application of Jensen's inequality [1, 18].

The remainder of the proof follows from a straightforward application of Zorn's Lemma similar to that in the Hahn-Banach Theorem. (The author thanks the referee for correcting an error in the above proof.)

The generalizations of the usual corollaries of the Hahn-Banach Theorem follow easily and we mention only the following:

COROLLARY. *If $x \neq 0$ and $y \neq 0$ are in the Hilbert spaces X and Y respectively, then there exists a bilinear functional f such that $f(x, y) = \|x\|\,\|y\|$ and $\|f\| = 1$.*

Added in Proof. The conjecture is false [2]. Does the bilinear extension property characterize Hilbert spaces?

TOPOLOGICAL ISOMORPHISM AND CONJUGATE SPACES

JAMES DUEMMEL, Western Washington State College

1. Let X be a Banach space with conjugate X' (also called its normed conjugate or dual [2, p. 185]). Suppose that a second norm is introduced on X' so that the two normed linear spaces on X' are topologically isomorphic or linearly homeomorphic [2, p. 85]. Can X' with this new norm be obtained as the conjugate of X with a suitable norm? The example of this paper shows that this cannot always be done.

2. Let (X, N) be a Banach space with conjugate (X', N'). Suppose M' is a

$\times_{k=1}^{n}(S_k \cup \{x_k\})$ for $x_k \notin S_k$, $k=1, 2, \cdots, n$. In fact, take $x_k \perp S_k$, and define $h(a_1x_1+s_1, \cdots, a_nx_n+s_n) = K\prod_{k=1}^{n} a_k\|x_k\| + f(s_1, \cdots, s_n)$ where $a_1, a_2, \cdots, a_n$ are scalars and K is the norm of f. It is immediate that the extension is multilinear, and we now show that the norm is the same.

$$|h(a_1x_1 + s_1, \cdots, a_nx_n + s_n)| \leqq K\left(\prod_{k=1}^{n}\|a_kx_k\| + \prod_{k=1}^{n}\|s_k\|\right)$$

$$\leqq K\prod_{k=1}^{n}\left(\|a_kx_k\|^{u_k} + \|s_k\|^{u_k}\right)^{1/u_k} \tag{1}$$

$$\leqq K\prod_{k=1}^{n}\left(\|a_kx_k\|^2 + \|s_k\|^2\right)^{1/2} = K\prod_{k=1}^{n}\|a_kx_k + s_k\|, \tag{2}$$

where $u_k \geqq 2$ and $1 \geqq \sum_{k=1}^{n} u_k^{-1}$. In (1) we have used a generalization of Hölder's inequality [1, 20], while (2) follows from an application of Jensen's inequality [1, 18].

The remainder of the proof follows from a straightforward application of Zorn's Lemma similar to that in the Hahn-Banach Theorem. (The author thanks the referee for correcting an error in the above proof.)

The generalizations of the usual corollaries of the Hahn-Banach Theorem follow easily and we mention only the following:

COROLLARY. *If $x \neq 0$ and $y \neq 0$ are in the Hilbert spaces X and Y respectively, then there exists a bilinear functional f such that $f(x, y) = \|x\|\,\|y\|$ and $\|f\| = 1$.*

Added in Proof. The conjecture is false [2]. Does the bilinear extension property characterize Hilbert spaces?

TOPOLOGICAL ISOMORPHISM AND CONJUGATE SPACES

JAMES DUEMMEL, Western Washington State College

1. Let X be a Banach space with conjugate X' (also called its normed conjugate or dual [2, p. 185]). Suppose that a second norm is introduced on X' so that the two normed linear spaces on X' are topologically isomorphic or linearly homeomorphic [2, p. 85]. Can X' with this new norm be obtained as the conjugate of X with a suitable norm? The example of this paper shows that this cannot always be done.

2. Let (X, N) be a Banach space with conjugate (X', N'). Suppose M' is a

By the remarks at the close of section 2, we can conclude that (Y'', M'') is *not* the conjugate of Y' with any norm. This gives the example mentioned in the opening paragraph.

4. Another interpretation. In the notation of section 2, let B' denote the closed unit sphere in (X', M'). From (1), the closed unit sphere B in $(X, P_{M'})$ is just the polar in X of B'. Let B^* be the polar in X' of B. From standard results [1, p. 52; 3, p. 244], B^* is the weak* closure of B', and B^* is the unit sphere of $P'_{M'}$. The norms $P'_{M'}$ and M' are the same iff $B^* = B'$, i.e., iff B' is weak* closed.

Thus, we can interpret our example as the construction in Y'' of a set U'' which is balanced, absorbing, bounded, convex, norm closed (also weak closed) but not weak* closed.

5. The identity map on Y'' is a topological isomorphism of (Y'', N'') onto (Y'', M''). In this sense, these spaces are the "same" although (Y'', M'') has lost the very property used to define (Y'', N''). For Banach spaces, it might be argued that congruence or isometric isomorphism [2, p. 84] is a better criterion of "sameness." The author has not been able to determine whether or not there exists a norm P' on Y' such that (Y'', P'') is congruent to (Y'', M'') as defined in the above example.

Acknowledgment. I am indebted to the referee for many helpful suggestions.

NEAR-RINGS WITH TRIVIAL MULTIPLICATIONS

J. J. Malone, Jr., University of Houston and Texas A and M University

In [1] the following question is raised: "Every group may be taken as the additive group of a near-ring. What characterizes the class of near-rings with the property that, if the group operation is taken as the addition of the near-ring, the only possible multiplications are $ab = 0$ or b?" This note answers that question.

A type of multiplication which may be defined on any group $(G, +)$ so that $(G, +, \cdot)$ is a near-ring will be called a trivial multiplication. Thus, a trivial multiplication does not depend upon the structure of $(G, +)$. Obviously, the two multiplications given in the question are trivial. The question is settled by showing that, if the order of G is greater than one, there exist additional trivial multiplications.

Let H be a subset of G such that $0 \notin H$. For $h \in H$ define $h \cdot x = x$, for every $x \in G$. For $g \in G - H$ define $g \cdot x = 0$, for every $x \in G$. Consider the product $x \cdot y \cdot z$ of three elements of G. If x or y is in $G - H$ or $z = 0$, the product is 0 regardless of

the manner of association. If x and y are in H, the product is z regardless of the manner of association. That the left-distributive law holds may be seen by comparing $x\cdot(y+z)$ and $x\cdot y+x\cdot z$ first for $x\in G-H$ and then for $x\in H$. In the first case both expressions reduce to 0 and in the second case both reduce to $y+z$. Thus $(G, +, \cdot)$ is a near-ring.

For each of the multiplications just defined $(G, +, \cdot)$ is a C-ring. These multiplications include the case in which $ab=0$, i.e., H is empty. If we remove the restriction $0\in H$ and take $H=G$, then $(G, +, \cdot)$ is a Z-ring, i.e., $ab=b$.

If G is of finite order n, we see that a minimum of $2^{n-1}+1$ near-rings may be defined on $(G, +)$. For the case in which G is cyclic, Clay [2] has shown, by also considering some nontrivial multiplications, that there are at least $2^{n-1}+n$ near-rings, $n>2$. For the case in which G is cyclic and has prime order, Jacobson [3] has shown that the exact number of near-rings is

$$2+\sum_{k}\left\{\sum_{j=1}^{k} C(k, j)\left(\frac{p-1}{k}\right)^{j}\right\}, \qquad k \mid p-1.$$

Since the group of order two admits only three multiplications (all of which are trivial), we conclude that all trivial multiplications have been described.

A MATHEMATICAL MICROSCOPE

G. T. CARGO, Syracuse University

1. Introduction. Pedagogically speaking, the purpose of this paper is to show that there are still frontiers of science where meaningful problems can be successfully attacked by persons possessing only a modest knowledge of undergraduate mathematics.

2. Recalcitrant microorganisms. The exponential function arises naturally in connection with many processes of change such as cooling of a hot body, damping on a telephone line, continuous compounding of interest, decay of radioactive material, and organic growth. Therefore, it came as no surprise to microbiologists (see [2]) when, time after time, experimental data indicated

the manner of association. If x and y are in H, the product is z regardless of the manner of association. That the left-distributive law holds may be seen by comparing $x\cdot(y+z)$ and $x\cdot y+x\cdot z$ first for $x\in G-H$ and then for $x\in H$. In the first case both expressions reduce to 0 and in the second case both reduce to $y+z$. Thus $(G, +, \cdot)$ is a near-ring.

For each of the multiplications just defined $(G, +, \cdot)$ is a C-ring. These multiplications include the case in which $ab=0$, i.e., H is empty. If we remove the restriction $0\in H$ and take $H=G$, then $(G, +, \cdot)$ is a Z-ring, i.e., $ab=b$.

If G is of finite order n, we see that a minimum of $2^{n-1}+1$ near-rings may be defined on $(G, +)$. For the case in which G is cyclic, Clay [2] has shown, by also considering some nontrivial multiplications, that there are at least $2^{n-1}+n$ near-rings, $n>2$. For the case in which G is cyclic and has prime order, Jacobson [3] has shown that the exact number of near-rings is

$$2+\sum_{k}\left\{\sum_{j=1}^{k} C(k, j)\left(\frac{p-1}{k}\right)^{j}\right\}, \qquad k \mid p-1.$$

Since the group of order two admits only three multiplications (all of which are trivial), we conclude that all trivial multiplications have been described.

A MATHEMATICAL MICROSCOPE

G. T. CARGO, Syracuse University

1. Introduction. Pedagogically speaking, the purpose of this paper is to show that there are still frontiers of science where meaningful problems can be successfully attacked by persons possessing only a modest knowledge of undergraduate mathematics.

2. Recalcitrant microorganisms. The exponential function arises naturally in connection with many processes of change such as cooling of a hot body, damping on a telephone line, continuous compounding of interest, decay of radioactive material, and organic growth. Therefore, it came as no surprise to microbiologists (see [2]) when, time after time, experimental data indicated

that the thermal death of microorganisms obeys first-order kinetics; in other words, if a population of P microorganisms is subjected to heat at a constant temperature, there exists a positive constant κ such that the number of microorganisms still alive at time t is $Pe^{-\kappa t}$. It is easy to understand the interest of applied microbiologists in this matter, for example, in connection with food processing and sterilization.

But Nature sometimes yields her secrets reluctantly. During the last decade, several investigators (see [1]) have reported instances of nonexponential thermal death for certain strains of bacterial spores, e.g., *Bacillus stearothermophilus*, where the deviations were not attributable to experimental errors. In this paper we shall devise a mathematical model which "explains" this phenomenon.

3. The model. A spore may be in one of three mutually exclusive states: activated, nonactivated, or dead. An *activated spore* is one which is capable of colony formation when properly nourished; in other words, it is a germinated spore. A *nonactivated spore* is a dormant spore which is capable of passing to the activated state upon being subjected to appropriate heat conditions.

It is difficult to determine which state a spore is in by means of a microscope. It is possible, however, to count the number of activated spores in a population by simply giving the population suitable nourishment and then counting the colonies which spring up—one colony for each activated spore. Instead of nourishing the whole population, it is often desirable to use an appropriate sampling procedure. Since the spore populations used in experiments are usually of the order of magnitude of 100,000, the use of some sampling technique is almost imperative. Moreover, the use of sampling permits one to continue an experiment, so that if a population is subjected to heat, one can obtain accurate estimates of the activated spore population at various times throughout the experiment.

When a population is heated at a constant temperature, it is customary to speak of the plot of the number of activated spores with respect to time as the *thermal death curve.*

If the initial population consists entirely of activated spores, then the thermal death curve is an exponential die-away curve whose equation is of the form $P(t)=Pe^{-\kappa t}$. If the initial population is a mixture of activated and nonactivated spores, then the thermal death curve usually exhibits an initial lag which is followed by an exponential die-away portion after a certain time delay (evidently, after almost no spores are left in the nonactivated state).

If the nonactivated spores and the activated spores were of equal heat resistance with respect to death and if the rate of activation were quite large, then the exponential die-away portion of the thermal death curve would extrapolate to the initial number of living spores. For certain strains of spores, however, the exponential portion of the death curve extrapolates to a point in excess of the initial number of living spores. There are several alternative hy-

potheses which could conceivably explain this anomaly. We shall incorporate the most reasonable hypothesis in our mathematical model.

In order to construct a mathematical model, we assume that: (a) the spores in a given population are all of a specific strain; (b) when heat is applied to a population, the temperature is held fixed; (c) a nonactivated spore must pass to the activated state before it can die; (d) an activated spore never enters the nonactivated state; (e) given a population of A activated spores, there is a positive number κ, the death-rate constant (which depends on the temperature and on the strain of spore but not on the number A), such that the number of spores which are still alive t units of time after the heating commences is $Ae^{-\kappa t}$; and (f) given a population of N nonactivated spores, there is a positive number α, the activation-rate constant, such that $Ne^{-\alpha t}$ spores are still in the nonactivated state t units of time after heating commences.

Now suppose that heat is applied to a hypothetical population consisting of $N(0)$ nonactivated and $A(0)$ activated spores. Since the population is not being nourished, the total number of spores in all three states remains constant. According to assumption (f), the number of nonactivated spores at time t is

$$N(t) = N(0)e^{-\alpha t} \qquad (0 \leqq t < \infty). \tag{1}$$

We seek an analytic expression for the number $A(t)$ of activated spores at time t. If we denote the number of living spores at time t by $L(t)$, then

$$L(t) = N(t) + A(t) \qquad (0 \leqq t < \infty). \tag{2}$$

In order to discover a differential equation involving $A(t)$, we shall examine the behavior of $A(t)$ over a small interval of time. To this end, let t be a fixed positive number, let h be a positive increment of time, and consider $A(t+h)$. Of the $A(t)$ spores in the activated state at time t, $A(t)e^{-\kappa h}$ are still in the activated state at time $t+h$ according to assumption (e). Of the $N(t)$ nonactivated spores at time t, $N(t)(1-e^{-\alpha h})$ become activated and possibly die by time $t+h$ according to assumption (f). Thus

$$A(t+h) = A(t)e^{-\kappa h} + N(t)(1 - e^{-\alpha h}) - R(t, t+h), \tag{3}$$

where $R(t, t+h)$ denotes the number of spores which are in the nonactivated state at time t but become activated and die in the time interval from t to $t+h$. Even if the $N(t)(1-e^{-\alpha h})$ spores which leave the nonactivated state in the time interval from t to $t+h$ were activated instantaneously at time t, only $N(t)(1-e^{-\alpha h})(1-e^{-\kappa h})$ of them would die by time $t+h$. Consequently,

$$0 \leqq R(t, t+h) \leqq N(t)(1 - e^{-\alpha h})(1 - e^{-\kappa h}). \tag{4}$$

From (4) we see at once that

$$\lim_{h \to 0+} \frac{R(t, t+h)}{h} = 0,$$

and, upon applying this last result to (3), we get

$$\lim_{h\to 0+} \frac{A(t+h)-A(t)}{h} = -\kappa A(t) + \alpha N(t). \tag{5}$$

If we assume that $A(t)$ is differentiable (or merely continuous) on the interval $0 \leqq t < \infty$, then (1) and (5) yield

$$A'(t) + \kappa A(t) = \alpha N(0) e^{-\alpha t}. \tag{6}$$

Depending upon whether $\alpha \neq \kappa$ or $\alpha = \kappa$, the solution of (6) is

$$A(t) = A(0)e^{-\kappa t} + \alpha N(0)\{e^{-\alpha t} - e^{-\kappa t}\}/(\kappa - \alpha) \qquad (\alpha \neq \kappa) \tag{7}$$

or

$$A(t) = \{A(0) + \kappa N(0)t\}e^{-\kappa t} \qquad (\alpha = \kappa). \tag{8}$$

If $N(0)=0$, the expressions for $A(t)$ given by (7) and (8) both reduce to $A(t)=A(0)e^{-\kappa t}$ as, indeed, they should according to assumption (e).

An examination, the details of which are left to the reader, of (7) and (8) shows that $A(t)$ attains a maximum for a positive value of t if and only if $\alpha N(0) > \kappa A(0)$; this accounts for the mysterious "peaks" in the thermal death curves observed by certain investigators.

4. The initial conditions. If, in a specific situation, the constants α, κ, $A(0)$, and $N(0)$ are known, then $A(t)$ is given by (7) or (8). The constant $A(0)$ is readily obtained by the process described in Section 3, but α, κ, and $N(0)$ are more evasive. Since values of $A(t)$ are relatively easy to obtain experimentally, one might substitute several of these values in (7) or (8) and attempt to solve the resulting system of simultaneous equations. We shall use a more sophisticated approach.

From (6) and (7) we see that if $\alpha \neq \kappa$, then

$$(d/dt)\{\log A(t)\} = -\kappa + \alpha N(0)\{A(0)e^{(\alpha-\kappa)t} + \alpha N(0)(1 - e^{(\alpha-\kappa)t})/(\kappa - \alpha)\}^{-1};$$

and, consequently, if $\alpha < \kappa$ and $N(0) \neq 0$, then

$$\lim_{t\to\infty} (d/dt)\{\log A(t)\} = -\alpha \qquad (\alpha < \kappa,\ N(0) \neq 0). \tag{9}$$

A similar argument shows that if $\alpha \geqq \kappa$, then

$$\lim_{t\to\infty} (d/dt)\{\log A(t)\} = -\kappa \qquad (\alpha \geqq \kappa). \tag{10}$$

If $\alpha \geqq \kappa$, then (10) shows that $-\kappa$ is the "limiting slope" as $t \to \infty$ of the graph of $\log A(t)$; in this case, κ can be estimated easily from the experimental data.

In order to obtain $N(0)$, it will suffice to determine $L(0)$ since $N(0)=L(0)-A(0)$ by (2).

From (1), (2), and (6) one easily deduces that $L'(t) = -\kappa A(t)$. Thus, for

complish indirectly with the naked eye things that one cannot easily do with a microscope, e.g., estimate the number of living spores at a given time t. Analogous situations of a qualitative nature are, of course, well known—it is very difficult to differentiate, by the use of a microscope, between the streptococcus of blood poisoning and the *Streptococcus cremoris* which gives the special flavor to sour cream butter, but they are easily distinguished by their biochemical activities.

In conclusion, we note that a mathematician cannot always be indifferent to the source of the differential equations which he undertakes to solve. In our model, the determination of the initial conditions involves as much mathematics as the derivation of the model itself (and we assumed that we knew *a priori* whether or not $\alpha<\kappa$). Some individuals would even go so far as to say that this phenomenon is characteristic of mathematical microbiology.

TWO DEFINITIONS OF SIMPLE CONNECTIVITY

RICHARD JOHNSONBAUGH, University of Oregon

Chevalley [1, p. 44] defines a simply connected topological space X as a space whose only covering spaces are those of the form (X^*, f) where f is a homeomorphism from X^* to X. Hereafter such spaces are called covering-simply-connected. This paper gives two examples contrasting this definition with the more usual definition given in terms of loops. (See, for example, [3] p. 234.) When we say "simply connected" we will be referring to this loop definition.

The following definitions are from [1, pp. 40–44]:

DEFINITION. *Let f be a continuous mapping of a space X^* into a space X. A subset E of X is evenly covered by X^* (with respect to f) if $f^{-1}(E)$ is not empty and every component of $f^{-1}(E)$ is mapped homeomorphically onto E by f.*

DEFINITION. *Let X be a topological space. A covering space (X^*, f) of X is a pair formed by a connected and locally connected space X^* and a continuous mapping f of X^* onto X such that each point of X has a neighborhood which is evenly covered by X^* (with respect to f).*

DEFINITION. *A space X is said to be covering-simply-connected* (c.s.c.) *if it is connected and locally connected and if, given any covering space (X^*, f) of X, f is a homeomorphism.*

TWO DEFINITIONS OF SIMPLE CONNECTIVITY

RICHARD JOHNSONBAUGH, University of Oregon

Chevalley [1, p. 44] defines a simply connected topological space X as a space whose only covering spaces are those of the form (X^*, f) where f is a homeomorphism from X^* to X. Hereafter such spaces are called covering-simply-connected. This paper gives two examples contrasting this definition with the more usual definition given in terms of loops. (See, for example, [3] p. 234.) When we say "simply connected" we will be referring to this loop definition.

The following definitions are from [1, pp. 40–44]:

DEFINITION. *Let f be a continuous mapping of a space X^* into a space X. A subset E of X is evenly covered by X^* (with respect to f) if $f^{-1}(E)$ is not empty and every component of $f^{-1}(E)$ is mapped homeomorphically onto E by f.*

DEFINITION. *Let X be a topological space. A covering space (X^*, f) of X is a pair formed by a connected and locally connected space X^* and a continuous mapping f of X^* onto X such that each point of X has a neighborhood which is evenly covered by X^* (with respect to f).*

DEFINITION. *A space X is said to be covering-simply-connected* (c.s.c.) *if it is connected and locally connected and if, given any covering space (X^*, f) of X, f is a homeomorphism.*

Example of a space which is simply connected but not covering-simply-connected. Let L' denote the set of ordinals less than the first uncountable ordinal. Let $L''=L'\times[0, 1[([0, 1[=\{x|\,0\leqq x<1\})$ with lexicographic order. Adjoin an endpoint to L'' and give the resulting space L the order topology. Identify the first and last points of L and give the resulting space C the quotient topology. C is a generalized circle. Notice that C is path connected. Since any loop f: $[0, 1]\to C$ has a homeomorph of $[0, 1]$ as its range and $[0, 1]$ is simply connected, it follows that C is simply connected.

Let I denote the integers and let $C^*=I\times L''$ with lexicographic order. Define f: $C^*\to C$ by $f(n, x)=x$. Then (C^*, f) is a covering space of C, f is not a homeomorphism, and hence C is not c.s.c.

It can be shown that C^* is c.s.c. and if the fundamental group, π, is defined as the set of homeomorphisms ϕ of C^*, the c.s.c. covering space, such that $f\circ\phi=f$ (see [1] p. 52), then π is isomorphic to the integers under $+$. Of course, the fundamental group given in terms of loops is trivial.

For the second example we require the following results:

LEMMA 1. [1, p. 42]. *Let (X^*, f) be a covering space of X and let Y be a connected and locally connected subspace of X. Let Y^* be any component of $f^{-1}(Y)$. If g is the restriction of f to Y^*, then (Y^*, g) is a covering space of Y.*

A special case of Lemma 1 is:

LEMMA 2. *If (X^*, f) is a covering space of X and Y is a* c.s.c. *subspace of X, then Y is evenly covered by X^*.*

LEMMA 3 [1, p. 57]. *Let (X^*, f) be a covering space of X. Let A and B be two closed, connected, and locally connected subsets of X which are both evenly covered by X^*. If $A\cap B$ is connected and not empty, then $A\cup B$ is evenly covered by X^*.*

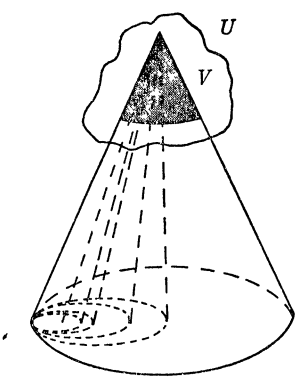

FIG. 1

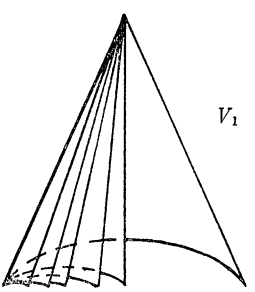

FIG. 2

Example of a space which is covering-simply-connected but not simply connected. Let B be the subset of the plane consisting of all circles with center at $(1/n, 0)$

fundamental group of $X_1 \vee X_2$ is not the free product of the groups of X_1 and X_2, these groups being trivial.

I wish to acknowledge the assistance of Dr. Richard M. Gillette in the preparation of this paper.

A THIRD DEFINITION OF LOCAL COMPACTNESS

J. L. Gross, Dartmouth College

1. Introduction. Two definitions of local compactness were recently discussed in "Classroom Notes," [1]. We rephrase these slightly:

(1.1) Definition. *A space X is locally compact if and only if each point of X has a compact neighborhood.*

(1.2) Definition. *A space X is locally compact if and only if each point of X has a closed compact neighborhood.*

In this paper we consider a third definition for local compactness. In general, if P is a topological property, we define a space X to be a locally-P space if and only if each point of X has a neighborhood basis consisting of P-subsets of X (e.g., local connectedness [2] p. 61). We now make the following definition:

(1.3) Definition. *A space X is locally compact if and only if each point of X has a neighborhood basis consisting of compact subsets of X.*

If we restrict our attention to Hausdorff or regular spaces, we know that (1.1) and (1.2) are equivalent [1]. It is not hard to see that, in such spaces, (1.1) implies (1.3) [2, p. 146]. Since (1.3) implies (1.1) in any space, we observe that in Hausdorff or regular spaces, all three local compactness properties are equivalent. (The terms "compact," "normal," and "regular" in this paper are those of Kelley [2].) This note provides counterexamples to show that, in arbitrary spaces, (1.3) does not imply (1.2), and that neither (1.2) nor compactness implies (1.3).

2. Counterexamples. (2.1) Example of a locally compact: (1.3) space which is not locally compact: (1.2): Let X be the set of real numbers. The open sets will be X, the empty set, and intervals $(-n, n)$ such that n is a positive integer. The set X is evidently the only closed set containing 0. But the open cover $\{(-n, n): n = 1, 2, \cdots\}$ of X has no finite subcover, and so X is not compact. Hence 0 does not have a closed compact neighborhood. Thus X is not locally

fundamental group of $X_1 \vee X_2$ is not the free product of the groups of X_1 and X_2, these groups being trivial.

I wish to acknowledge the assistance of Dr. Richard M. Gillette in the preparation of this paper.

A THIRD DEFINITION OF LOCAL COMPACTNESS

J. L. Gross, Dartmouth College

1. Introduction. Two definitions of local compactness were recently discussed in "Classroom Notes," [1]. We rephrase these slightly:

(1.1) Definition. *A space X is locally compact if and only if each point of X has a compact neighborhood.*

(1.2) Definition. *A space X is locally compact if and only if each point of X has a closed compact neighborhood.*

In this paper we consider a third definition for local compactness. In general, if P is a topological property, we define a space X to be a locally-P space if and only if each point of X has a neighborhood basis consisting of P-subsets of X (e.g., local connectedness [2] p. 61). We now make the following definition:

(1.3) Definition. *A space X is locally compact if and only if each point of X has a neighborhood basis consisting of compact subsets of X.*

If we restrict our attention to Hausdorff or regular spaces, we know that (1.1) and (1.2) are equivalent [1]. It is not hard to see that, in such spaces, (1.1) implies (1.3) [2, p. 146]. Since (1.3) implies (1.1) in any space, we observe that in Hausdorff or regular spaces, all three local compactness properties are equivalent. (The terms "compact," "normal," and "regular" in this paper are those of Kelley [2].) This note provides counterexamples to show that, in arbitrary spaces, (1.3) does not imply (1.2), and that neither (1.2) nor compactness implies (1.3).

2. Counterexamples. (2.1) Example of a locally compact: (1.3) space which is not locally compact: (1.2): Let X be the set of real numbers. The open sets will be X, the empty set, and intervals $(-n, n)$ such that n is a positive integer. The set X is evidently the only closed set containing 0. But the open cover $\{(-n, n): n = 1, 2, \cdots\}$ of X has no finite subcover, and so X is not compact. Hence 0 does not have a closed compact neighborhood. Thus X is not locally

nor in $B(1-1/M, M-1)$. Hence $\mathcal{C}$ does not contain a finite subcover of U and so U is not compact. Thus Y is not locally compact: (1.3).

(2.3) Remark: Notice that the space Y of Example (2.1) is normal but not regular. It is normal because all nonvoid closed subsets of Y contain the point (1, 1). It is not regular because (0, 0) is in every open subset of Y.

A STURMIAN THEOREM FOR POSITIVE MATRICES

KURT KREITH, University of California, Davis

The similarity between many of the concepts of matrix theory and linear differential equations should be a source of interest to the undergraduate student who is exposed to both of these subjects. While a full explanation of the relationship between matrix theory and other linear problems must wait for a course on functional analysis, it does seem worthwhile to point out appropriate similarities even before full explanations can be given.

One subject which is often treated in elementary differential equations but for which matrix analogues are apparently neglected is that of Sturmian theorems. In order to motivate such an analogue it is convenient to state a slightly weakened version of Sturm's theorems as follows. (The positiveness of $a(t)$ and $b(t)$ is not essential except in this formulation.)

Let A and B be formal differential operators defined by

$$\begin{aligned} Ax(t) &= -\frac{1}{a(t)}\frac{d^2}{dt^2}x(t), \\ Bx(t) &= -\frac{1}{b(t)}\frac{d^2}{dt^2}x(t), \end{aligned} \tag{1}$$

where $a(t)$ and $b(t)$ are continuous positive functions. Let $t_1<t_2$ be two arbitrary but fixed real numbers and define the boundary conditions

$$\begin{aligned} \theta x(t_1) - x'(t_1) &= 0, \\ \phi x(t_2) + x'(t_2) &= 0, \end{aligned} \tag{2}$$

where θ and ϕ are real numbers. The notation $\theta=\infty$ $(\phi=\infty)$ will be used to denote the boundary condition $x(t_1)=0$ $(x(t_2)=0)$.

We use the formal operators (1) and the boundary conditions (2) to define differential operators $A_{\theta\phi}(B_{\theta\phi})$ whose domain consists of functions which are twice continuously differentiable and satisfy (2), and which operate on their domains according to the rule (1).

nor in $B(1-1/M, M-1)$. Hence $\mathcal{C}$ does not contain a finite subcover of U and so U is not compact. Thus Y is not locally compact: (1.3).

(2.3) Remark: Notice that the space Y of Example (2.1) is normal but not regular. It is normal because all nonvoid closed subsets of Y contain the point (1, 1). It is not regular because (0, 0) is in every open subset of Y.

$$\begin{aligned} Ax(t) &= -\frac{1}{a(t)}\frac{d^2}{dt^2}x(t), \\ Bx(t) &= -\frac{1}{b(t)}\frac{d^2}{dt^2}x(t), \end{aligned} \tag{1}$$

where $a(t)$ and $b(t)$ are continuous positive functions. Let $t_1<t_2$ be two arbitrary but fixed real numbers and define the boundary conditions

$$\begin{aligned} \theta x(t_1) - x'(t_1) &= 0, \\ \phi x(t_2) + x'(t_2) &= 0, \end{aligned} \tag{2}$$

where θ and ϕ are real numbers. The notation $\theta=\infty$ $(\phi=\infty)$ will be used to denote the boundary condition $x(t_1)=0$ $(x(t_2)=0)$.

We use the formal operators (1) and the boundary conditions (2) to define differential operators $A_{\theta\phi}(B_{\theta\phi})$ whose domain consists of functions which are twice continuously differentiable and satisfy (2), and which operate on their domains according to the rule (1).

satisfies $\beta>1$. By the theorem of Perron and Frobenius, no other eigenvalue of B can have a nonnegative eigenvector. In particular, $B\mathbf{x}=\mathbf{x}$ cannot have a nonnegative solution other than $\mathbf{x}=\mathbf{0}$.

ON THE GEOMETRY OF NUMBERS IN ELEMENTARY NUMBER THEORY

G. E. ANDREWS, Pennsylvania State University

In most elementary texts on number theory, the geometry of numbers is rarely mentioned. This is probably due partly to the feeling that the introduction of convexity, n-dimensional geometry, etc., in an elementary course unnecessarily burdens students; also most of the theorems in the geometry of numbers seem beyond the field of interest of a first course in number theory. The following proof of the theorem on the linear diophantine equation gives the flavor of the geometry of numbers but does not call for any knowledge beyond a little analytic geometry.

We remark that the geometric interpretation of the linear Diophantine equation used here was originally given by H. J. S. Smith [4, p. 147], but Smith's proof is entirely algebraic, depending on the theory of continued fractions. A totally different geometric proof depending on the construction of regular polygons was given by P. Johnson [2].

In the following, $P=(p_1, p_2)$, $Q=(q_1, q_2)$, $\cdots$ will denote points of the plane; $O=(0, 0)$. A lattice point is a point with integral coordinates.

LEMMA. *If there exists no integer $b>1$ such that $b\mid a_1$ and $b\mid a_2$ (where a_1 and a_2 are integers with $a_1>0$, $a_2>0$), then all the lattice points on the line $L_0=\{(x, y); y=a_2x/a_1\}$ are given by (ta_1, ta_2) with $t=0, \pm1, \pm2, \cdots$.*

Proof. Let R be the lattice point with positive coordinates nearest the origin on L_0. Clearly R exists since there are at most a_1a_2 lattice points (x^*, y^*) with $1\leqq x^*\leqq a_1$ and $1\leqq y^*\leqq a_2$. Assume that the n lattice points with positive coordinates on L_0 nearest O are (r_1, r_2), $(2r_1, 2r_2)$, $\cdots$, (nr_1, nr_2). Suppose there is a lattice point P such that $nr_1<p_1<(n+1)r_1$ and $nr_2<p_2<(n+1)r_2$. Then $0<p_1-nr_1<r_1$ and $0<p_2-nr_2<r_2$; hence, (p_1-nr_1, p_2-nr_2) is a lattice point on L_0 nearér to O than R. Hence by mathematical induction (and by the fact that L_0 is symmetric with respect to O), all lattice points on L_0 are given by (tr_1, tr_2) with $t=0, \pm1, \pm2, \cdots$. Thus $(a_1, a_2)=(t_0r_1, t_0r_2)$ for some positive integer t_0. Thus by the hypothesis of the lemma, we must have $t_0=1$. Hence $A=R$.

For further use note that the distance between (ta_1, ta_2) and $((t+1)a_1, (t+1)a_2)$ is given by $(a_1^2+a_2^2)^{1/2}$.

satisfies $\beta>1$. By the theorem of Perron and Frobenius, no other eigenvalue of B can have a nonnegative eigenvector. In particular, $B\mathbf{x}=\mathbf{x}$ cannot have a nonnegative solution other than $\mathbf{x}=\mathbf{0}$.

ON THE GEOMETRY OF NUMBERS IN ELEMENTARY NUMBER THEORY

G. E. ANDREWS, Pennsylvania State University

In most elementary texts on number theory, the geometry of numbers is rarely mentioned. This is probably due partly to the feeling that the introduction of convexity, n-dimensional geometry, etc., in an elementary course unnecessarily burdens students; also most of the theorems in the geometry of numbers seem beyond the field of interest of a first course in number theory. The following proof of the theorem on the linear diophantine equation gives the flavor of the geometry of numbers but does not call for any knowledge beyond a little analytic geometry.

We remark that the geometric interpretation of the linear Diophantine equation used here was originally given by H. J. S. Smith [4, p. 147], but Smith's proof is entirely algebraic, depending on the theory of continued fractions. A totally different geometric proof depending on the construction of regular polygons was given by P. Johnson [2].

In the following, $P=(p_1, p_2)$, $Q=(q_1, q_2)$, $\cdots$ will denote points of the plane; $O=(0, 0)$. A lattice point is a point with integral coordinates.

LEMMA. *If there exists no integer $b>1$ such that $b\mid a_1$ and $b\mid a_2$ (where a_1 and a_2 are integers with $a_1>0$, $a_2>0$), then all the lattice points on the line $L_0=\{(x, y); y=a_2x/a_1\}$ are given by (ta_1, ta_2) with $t=0, \pm1, \pm2, \cdots$.*

Proof. Let R be the lattice point with positive coordinates nearest the origin on L_0. Clearly R exists since there are at most a_1a_2 lattice points (x^*, y^*) with $1\leqq x^*\leqq a_1$ and $1\leqq y^*\leqq a_2$. Assume that the n lattice points with positive coordinates on L_0 nearest O are (r_1, r_2), $(2r_1, 2r_2)$, $\cdots$, (nr_1, nr_2). Suppose there is a lattice point P such that $nr_1<p_1<(n+1)r_1$ and $nr_2<p_2<(n+1)r_2$. Then $0<p_1-nr_1<r_1$ and $0<p_2-nr_2<r_2$; hence, (p_1-nr_1, p_2-nr_2) is a lattice point on L_0 nearér to O than R. Hence by mathematical induction (and by the fact that L_0 is symmetric with respect to O), all lattice points on L_0 are given by (tr_1, tr_2) with $t=0, \pm1, \pm2, \cdots$. Thus $(a_1, a_2)=(t_0r_1, t_0r_2)$ for some positive integer t_0. Thus by the hypothesis of the lemma, we must have $t_0=1$. Hence $A=R$.

For further use note that the distance between (ta_1, ta_2) and $((t+1)a_1, (t+1)a_2)$ is given by $(a_1^2+a_2^2)^{1/2}$.

THEOREM. *If there exists no integer $b>1$ such that $b \mid a_1$ and $b \mid a_2$ (where a_1 and a_2 are integers with $a_1>0$, $a_2>0$), then there exist integers k and m such that $ka_1+ma_2=1$.*

Proof. Consider the set Σ of all lines parallel to $L_0=\{(x, y); y=a_2x/a_1\}$ and containing lattice points. If $L\in\Sigma$, P is a lattice point on L, and $d(L)$ is the distance between L and L_0, then the area of the triangle $\triangle(OAP)$ is $\left|\frac{1}{2}(a_1p_2-a_2p_1)\right| = \frac{1}{2}(a_1^2+a_2^2)^{1/2}d(L)$. Hence $d(L)=n\cdot(a_1^2+a_2^2)^{-1/2}$ where n is an integer. It is easy to verify that the adjacent lines of Σ are all the same distance d apart, for translating a lattice point on one line to a lattice point on another line transforms Σ into itself. Consider the square S of side ρ centered on O with two sides parallel to L_0. There are $\rho^2+O(\rho)$ lattice points inside or on S (a fact easily established by the technique of Gauss which is well described in [1, pp. 29–30]). But there are at most $\rho/d+1$ lines in S containing lattice points and parallel to L_0, and on each such line there are at most $\rho/(a_1^2+a_2^2)^{1/2}+1$ lattice points (by the note following the lemma and by the remarks concerning the translation properties of Σ). Hence

$$\rho^2 + O(\rho) \leqq \rho^2 d^{-1}(a_1^2 + a_2^2)^{-1/2} + \rho d^{-1} + \rho\cdot(a_1^2 + a_2^2)^{-1/2} + 1$$

which is true for all positive ρ only if $d\leqq(a_1^2+a_2^2)^{-1/2}$. Since we have already established that $d\geqq(a_1^2+a_2^2)^{-1/2}$, we obtain $d=(a_1^2+a_2^2)^{-1/2}$. Thus there is a lattice point P on a line a perpendicular distance $(a_1^2+a_2^2)^{-1/2}$ from L_0. Thus the area of the triangle $\triangle(OAP)$ is

$$\tfrac{1}{2}(a_1^2 + a_2^2)^{1/2}(a_1^2 + a_2^2)^{-1/2} = \tfrac{1}{2} = \left|\tfrac{1}{2}(a_1p_2 - a_2p_1)\right| .$$

Hence one of the pairs $(k, m)=(p_2, -p_1)$ or $(-p_2, p_1)$ must fulfill the conclusion of the theorem.

Thus a standard technique from the geometry of numbers yields the essential result needed to develop such properties as unique factorization, etc., [3, Chapter 2]. In conclusion, I should like to express my appreciation to a very helpful referee; in particular, he brought references [1] and [4] to my attention.

INSTITUTIONAL INFLUENCES IN THE GRADUATE TRAINING OF PRODUCTIVE MATHEMATICIANS

B. R. SIEBRING, University of Wisconsin, Milwaukee

Recently the American Council on Education published an evaluation of graduate education [1]. Essentially this evaluation was a compilation of the opinions of experts in the various academic disciplines on the quality of graduate faculties and the effectiveness of graduate programs. This paper is the result of an attempt at another type of evaluation of graduate instruction in mathematics. The criterion of this evaluation is the productivity of the doctoral graduates of the various mathematics departments. Essentially this study compares graduate departments in mathematics in terms of (a) number of productive Ph.D. mathematicians graduated, (b) number of papers published by the Ph.D. graduates, (c) the proportion of Ph.D. graduates who become productive mathematicians, and finally (d) the number of papers published per Ph.D. graduate in mathematics. For the purposes of this investigation a "productive mathematician" is defined as one who has published at least one paper which was reviewed in the *Mathematical Reviews* through the year 1964.

The investigation is limited to mathematicians who received their doctorates in the 1950–59 decade, who were listed in the *Combined Membership List (1963–1964) of the American Mathematical Society, Mathematical Association of America, and Society for Industrial and Applied Mathematics* [2] and whose biographies were found in the 9th or 10th editions of the *American Men of Science* [3].

The top ten institutions in terms of the number of productive mathematicians produced are listed in Table I. Upon comparison of this listing to rankings of the American Council on Education, one notices a high degree of similarity. Eight of the top ten institutions according to the A.C.E. rating on quality of graduate faculty are among the top ten institutions in Table I. Also seven of the top ten institutions according to the A.C.E. rating on effectiveness of the graduate programs are among the top ten institutions in Table I. One institution which stands out more favorably in Table I than in the A.C.E. study is New York University. It should be noted that the top ten institutions in Table I provided the graduate education for over forty percent of the productive mathematicians of this period.

Table II lists the top ten institutions according to the number of papers published by their doctoral graduates in mathematics. Again one notices the high degree of similarity to the A.C.E. rankings. Over 47 percent of the papers published by mathematicians who received their doctorate degrees in the 1950–

1959 decade were written by graduates of the top ten institutions.

One might conclude that the institutions which ranked high in Tables I and II were there because of the large output of Ph.D.'s in mathematics. That is,

TABLE III. Institutions ranked by percent of total output of Ph.D. mathematicians in the 1950–59 decade who became productive mathematicians

[3] The letters A.P. in this column refer to institutions not ranked by the A.C.E. but classed as "Adequate plus."

institutions which produced large numbers of Ph.D.'s in mathematics would naturally be expected to account for a large number of productive mathematicians.

A better evaluation of an institution's productivity might therefore be based upon an institution's total output of Ph.D.'s in mathematics. Tables III and IV present this type of evaluation. Table III ranks institutions according to the percent of the total output of Ph.D. mathematicians in the 1950–59 decade who became productive mathematicians. The total output of Ph.D.'s in mathematics by institution was obtained from the U.S. Office of Education document, *Degrees in the Biological and Physical Sciences, Mathematics, and Engineering* [4]. Table IV ranks the institutions according to the number of publications per

* The A.C.E. study ranked University of California campuses individually.

Ph.D. mathematician graduated in the 1950–59 decade. Upon comparing these rankings with those in the A.C.E. report, one notices an appreciable difference. Only two of the top ten institutions in each of the A.C.E. rankings appear among the top ten in Table III. The top ten institutions in Table IV include five from the top ten institutions in each of the A.C.E. rankings. Tables III and IV show quite clearly that small departments unable to support a program or faculty of national renown are still capable of providing quality education for small numbers of Ph.D. candidates. It is interesting to note that only one institution, Harvard University, maintains a position among the top ten institutions in all four rankings in this study, as well as in the two rankings of the A.C.E. report.

In order that institutions might be compared by geographical location, composite data for each of the major geographical divisions were tabulated. These

TABLE V. Composite data for the major geographical divisions

* These data exclude foreign institutions.

data are presented in Table V.

Although this study presents evaluations which are less subjective than those in the A.C.E. report, it may be criticized on the following grounds:

(1) A study of this nature can never be current. The A.C.E. report has a time lag of only several years, but this study has a time lag of from five to fifteen years. That is, this study evaluates the performance of the departments as they were in the fifties.

(2) Admittedly publication counting is a very narrow measure of research productivity, as the research value of all papers is not uniform. One article may represent as much work as several others.

(3) Whether a productive mathematician is included in this study or not depends on whether his biography appeared in the *American Men of Science*. The reliability of this study depends on the assumption that the proportion of productive mathematicians who submit their biographies to the *American Men of Science* is independent of doctoral origin. Yet it is possible that graduates of some institutions are more likely to submit their biographies than are graduates of other institutions.

In spite of these deficiencies, the writer feels that evaluations of this type should be considered in contemplating the relative merits of departments offering graduate instruction in mathematics.

incorporate such a seemingly mundane feature as specific training for teaching elementary school mathematics? If so, is there a substantial number of prospective elementary teachers who would persevere in the rigorous training necessary to excel both in humanitarian and cultural endeavors as well as in the teaching of mathematics?

Unless such challenges are honestly met, we will continue to develop mathematical neuroses in elementary teachers and their pupils. The details of a teacher preparation program such as that prescribed by CUPM will have to be resolved by each institution according to its own peculiar structure, but its ultimate impact must rely upon a core of college teachers who possess the rare talent of communicating mathematical knowledge and technique to students who are prospective teachers. Professors who serve in such a capacity must be willing to, and be free to, consider teaching their primary function. Will you fight the necessary curriculum battles and the publish or perish deterrents for the privilege of being one of these professors?

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, University of Massachusetts; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before March 31, 1968. ***Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.***

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, University of Massachusetts; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before March 31, 1968. ***Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.***

E 2000 [1967,719] **Correction.** *Proposed by Howard Kleiman, Queensborough Community College, New York*

Let q be any prime number >2. Show that

$$\sum_{n=1}^{q} x^{q-n} \left| \left\{ \sum_{m,n=1}^{q-1} x^{mn} + q - 1 \right\} . \right.$$

E 2031. *Proposed by D. S. Mitrinović, University of Belgrade, Yugoslavia*

a is any real number. Prove the inequality

$$\left|\sqrt[3]{-\frac{a}{2}+\sqrt{\frac{a^2}{4}+\frac{1}{27}}}+\sqrt[3]{-\frac{a}{2}-\sqrt{\frac{a^2}{4}+\frac{1}{27}}}\right|<\sqrt[3]{|a|}.$$

E 2032. *Proposed by D. S. Mitrinović, University of Belgrade, Yugoslavia*

Prove the following inequality

$$\min[(b-c)^2,(c-a)^2,(a-b)^2]\leqq\tfrac{1}{2}(a^2+b^2+c^2),$$

with a, b, c, real numbers.

Study the analogous problem for $\min[(a_k-a_i)^2]$, $k<i$, k, $i=1, 2, \cdots, n$.

E 2033. *Proposed by D. R. Rao, Secunderabad, India*

Show that $p=1093$ simultaneously satisfies

$$2^{(p-1)/2}+1\equiv 0 \pmod{p^2};$$

$$2^j-2^{j-k}+2^{j-2k}-\cdots+1\equiv 0 \pmod{p^2},$$

where $j=\frac{1}{2}[p-(2k+1)]$, $k=2+4s_n$ $(n=0, 1, 2, 3, 4)$, and s_n is the sum of the first n natural numbers.

E 2034. *Proposed by Merrill Barneby, Wisconsin State University*

Show that there exist solutions in positive integers of the system:

$$a+b+c=x+y, \qquad a^3+b^3+c^3=x^3+y^3.$$

In particular, show that there are infinitely many in which a, b, c, form an arithmetic progression.

SOLUTIONS OF ELEMENTARY PROBLEMS

A Polynomial Identity

E 1829 [1965, 1021; 1967, 323]. *Proposed by M. J. Pascual and S. D. Beck, Watervliet Arsenal, N.Y.*

If m is a positive integer and x is arbitrary, establish the following identity:

$$\sum_{k=m}^{2m-1}\binom{2m-1}{k}x^k(1-x)^{2m-1-k}=\sum_{k=m}^{2m-1}\binom{k-1}{m-1}x^m(1-x)^{k-m}.$$

II. *Additional Comments by W. C. Guenther, University of Wyoming.*

(1) The identity is more general than claimed. It should be

$$(*)\qquad \sum_{k=m}^{r}\binom{k-1}{m-1}x^m(1-x)^{k-m}=\sum_{k=m}^{r}\binom{r}{k}x^k(1-x)^{r-k},$$

where m and r are positive integers, $r \geqq m$, which also holds for all x.

(2) An important use of (*) is in evaluating cumulative negative binomial sums in terms of ordinary binomial sums. By using both the Harvard table [2] and the Ordnance Corps Table [7] one can obtain values to at least 5 significant figures for the right hand side of (*) for

$$x = .01(.01)\ .99,\ r = 1(1)\ 150(10)\ 200(20)\ 500(50)\ 1000.$$

This useful fact is apparently not well known although it appears in several texts, e.g. [1].

(3) The literature has many proofs for $0 < x < 1$. See [4] and [5] for bibliography. The earliest paper mentioned is [3], 1933, but the result was probably known earlier. The result is also implied by a paper by Rider [6] appearing in this MONTHLY.

(4) If one is acquainted with the binomial and negative binomial, then the proof is easy by a probability argument. Suppose we set as a goal the obtaining of m successes in a binomial type experiment, with probability of success on a single trial being x, but agree to repeat the experiment no more than r times. Our goal can be achieved in two ways. First, if the mth success is obtained on either the mth, $(m+1)$th, $\cdots$, rth repetition, the goal is accomplished. The probability that this series of events happens is given by the left hand side of (*). The second way to achieve the goal in r repetitions of the experiment is to plan to repeat the experiment r times and obtain m, $m+1$, $\cdots$, or r successes. The probability that the latter series of events happens is given by the right hand side of the identity. Hence for $0 < x < 1$ the identity is established. A well-known theorem of algebra states that if two polynomials of degree r are equal for more than r values, they are equal for all values.

Minimal Subseries—A Class of Convergent Series

E 1836 [1965, 1128]. *Proposed by D. E. Daykin, University of Malaya, Kuala Lumpur*

Given a convergent series $\sum_{i=0}^{\infty} u_i$ of positive terms u_i, find the greatest

lower bound g of $\sum_{i=0}^{\infty} \epsilon_i u_i$ over all sequences $\{\epsilon_i\}$, where ϵ_i is 0 or 1 and $\epsilon_{i-1}+\epsilon_i+\epsilon_{i+1}>0$ for $i \geqq 1$.

Solution by the proposer. If a sequence $\{\epsilon_i\}$ has $\epsilon_{k-1}=\epsilon_k=\epsilon_{k+1}=1$ for some $k \geqq 1$, then $\sum_{i=0}^{\infty} \epsilon_i u_i > \sum_{i=0}^{\infty} \epsilon_i' u_i$ where $\epsilon_i' = \epsilon_i$ for $i \neq k$ but $\epsilon_k' = 0$. Hence we may also assume that $\epsilon_{i-1}+\epsilon_i+\epsilon_{i+1}<3$ for $i \geqq 1$. For $n \geqq 1$ consider all possible nth partial sums $\sum_{i=0}^{n} \epsilon_i u_i$. Let p_n, q_n, r_n and s_n denote the smallest of these sums which end with $(\epsilon_{n-1}, \epsilon_n)$ equal to (0, 0), (1, 0), (0, 1) and (1, 1) respectively. Then the numbers p_n, q_n, r_n, s_n satisfy the recurrence relations

$$p_1 = 0, \qquad q_1 = u_0, \qquad r_1 = u_1, \qquad s_1 = u_0 + u_1,$$

and for $n \geqq 1$,

$$p_{n+1} = q_n, \quad q_{n+1} = \min(r_n, s_n), \quad r_{n+1} = u_{n+1} + \min(p_n, q_n), \quad s_{n+1} = u_{n+1} + r_n.$$

For $n \geqq 1$ let $m_n = \text{minimum } (p_n, q_n, r_n, s_n)$. Then the sequence $\{m_n\}$ is non-decreasing bounded above by $\sum_{i=0}^{\infty} u_i < \infty$, and so has a finite limit h. We wish to show that $h=g$ for then we will have a method for determining g.

Now $h \leqq g$ because $m_n \leqq \sum_{i=0}^{n} \epsilon_i u_i < \sum_{i=0}^{\infty} \epsilon_i u_i$ for all sequences $\{\epsilon_i\}$. Hence it only remains to show that, given $\delta>0$, there is some sequence $\{\epsilon_i\}$ with $\sum_{i=0}^{\infty} \epsilon_i u_i < h+\delta$. For this δ there is an integer G such that $\sum_{i=G+1}^{\infty} u_i < \delta$, and for this G there is a sequence $\{\epsilon_i\}$ such that $\sum_{i=0}^{G} \epsilon_i u_i = m_G < h$, so for this sequence $\sum_{i=0}^{\infty} \epsilon_i u_i = m_G + \sum_{i=G+1}^{\infty} \epsilon_i u_i < h+\delta$ and we are through.

Equivalence Classes of Poker Hands

E 1865 [1966, 309]. *Proposed by E. O. Thorp, New Mexico State University*

(a) How many distinct hands (i.e. of different values) are there in a 5-card draw poker? More precisely, the hands can be grouped into equivalence classes such that the hands in any equivalence class are equal (tie), and such that, given any pair of equivalence classes, all the hands in one equivalence class beat all the hands in the other. The problem is to find how many equivalence classes there are.

(b) Which equivalence class (or classes) determines the median hand?

Solution by D. C. B. Marsh, Colorado School of Mines. By the very nature of five-card draw, this is an ill-defined problem; on the matter of equivalence classes one might be tempted to include "Skip straights" et al.; also, the category full house Kings over Queens would technically beat full house Kings over Jacks, but in practice the winner would be the one with the quicker draw . . . and so it goes.

However, one may compute 7,462 equivalence classes with the median falling between "High card, AKQJ7" and "High card, AKQJ6."

TABULATED:

Name of class	*No. of classes*	*No. of hands per class*	*Total no. of hands*
Straight flush	10	4	40
Four of a kind	156	4	624
Full house	156	24	3,744
Flush	1,277	4	5,108
Straight	10	1,020	10,200
Three of a kind	858	64	54,912
Two pair	858	144	123,552
One pair	2,860	384	1,098,240
High card	1,277	1,020	1,302,540

Also solved by Walter Bluger, John Berslem, Allan Gottleib, Rudolf Ondrejka, Robert Prener, David Tranberg, and J. E. Wilkins, Jr.

Solvers noted that the definition of "equivalence classes" should be more explicit. Do hands below a pair go into one class or should "ace high" and "king high" be in separate classes? Should "four of a kind" be a single class or broken up according to the fifth card? How can "aces full on kings" and "aces full on queens" be compared since they cannot compete in a showdown? Different interpretations lead to different solutions. (Several solvers failed to observe that the median hand does not occur in the median class.

Determinants Related to Pascal's Theorem

E 1870 [1966, 310]. *Proposed by Arun Sanyal, Indian Institute of Technology, Kharagpur*

(1) Prove that the third order determinant (a_{ij}) vanishes identically, where

$$a_{11} = (A + B)DE - (D + E)AB, \quad a_{12} = AB - DE, \quad a_{13} = A + B - D - E,$$
$$a_{21} = (B + C)EF - (E + F)BC, \quad a_{22} = BC - EF, \quad a_{23} = B + C - E - F,$$
$$a_{31} = (C + D)FA - (F + A)CD, \quad a_{32} = CD - FA, \quad a_{33} = C + D - F - A.$$

(2) The same, where

$$a_{11} = \sin(A + B)\cos(D - E) - \sin(D + E)\cos(A - B),$$
$$a_{12} = \cos(A + B)\cos(D - E) - \cos(D + E)\cos(A - B),$$
$$a_{13} = \cos(A + B + D + E), \quad a_{23} = \cos(B + C + E + F),$$
$$a_{33} = \cos(C + D + F + A),^*$$
$$a_{21} = \sin(B + C)\cos(E - F) - \sin(E + F)\cos(B - C),$$
$$a_{22} = \cos(B + C)\cos(E - F) - \cos(E + F)\cos(B - C),$$
$$a_{31} = \sin(C + D)\cos(F - A) - \sin(F + A)\cos(C - D),$$
$$a_{32} = \cos(C + D)\cos(F - A) - \cos(F + A)\cos(C - D).$$

Solution suggested by the proposer. Consider six points P_i chosen on the parabola $y^2 = x$ as follows: $P_1(A^2, A)$, $P_2(B^2, B)$, $P_3(C^2, C)$, $P_4(D^2, D)$, $P_5(E^2, E)$,

$P_6(F^2, F)$. The point of intersection of lines P_1P_2 and P_4P_5 is determined routinely to be

$$\left(\frac{(A+B)DE-(D+E)AB}{D+E-A-B}, \frac{DE-AB}{D+E-A-B}\right).$$

Finding, similarly, the intersections of P_2P_3 with P_5P_6 and of P_3P_4 with P_6P_1, and recalling Pascal's theorem, the determinant which indicates the collinearity of the three points is immediately reduced to (1).

We choose $(\cos 2A, \sin 2A)$, $(\cos 2B, \sin 2B)$, etc., as 6 points on the circle $x^2+y^2=1$, and follow the same procedure with some additional trigonometric reductions. This gives a determinant which agrees with (2) except that the third column (*) should be $a_{13}=\sin(A+B-D-E)$, $a_{23}=\sin(B+C-E-F)$, $a_{33}=\sin(C+D-F-A)$.

Also solved, (1) only, by Michael Goldberg, D. C. B. Marsh, and P. V. Murty (India).

An Increasing Function

E 1880 [1966, 411]. *Proposed by Robert Schlesinger, Washington University, St. Louis, Mo.*

Show that $f(t)=(t-\sin t)(\pi-t-\sin t)$ is an increasing function of t for $0<t<\frac{1}{2}\pi$.

I. *Solution by R. G. Kayel, Grumman Aircraft, Bethpage, N.Y.* Assume that $f'(t)\leqq 0$ for some t, $0<t<\frac{1}{2}\pi$. Then

$$f'(t) = (1-\cos t)(\pi - t - \sin t) - (t - \sin t)(1+\cos t) \leqq 0$$

implies

$$\sin t - t \leqq \frac{1-\cos t}{1+\cos t}\cdot(\sin t + t - \pi) < \sin t + t - \pi,$$

which gives $\pi<2t$ for some t, $0<t<\frac{1}{2}\pi$. This contradiction shows $f'(t)>0$ for all t, $0<t<\frac{1}{2}\pi$.

II. *Solution by L. A. Steen, Saint Olaf College.* We need only show that $f'(t)=\pi-\pi\cos t-2t+\sin 2t$ is positive for $0<t<\frac{1}{2}\pi$. Since $f''(t)=\sin t(\pi-4\sin t)$, f' is strictly increasing on $(0, \sin^{-1}\pi/4)$ and strictly decreasing on $(\sin^{-1}\pi/4, \frac{1}{2}\pi)$. But $f'(0)=f'(\frac{1}{2}\pi)=0$. Therefore $f'>0$ on $(0, \frac{1}{2}\pi)$.

Also solved by Anders Bager (Denmark), Merrill Barnebey R. A. Bell, J. P. Celenza, Yu Chang & Sidney Spital, R. J. Cormier, P. M. Ellis, M. A. Ettrick, H. J. Fletcher, A. S. Langford, Arthur Lieberman, Dan Marcus, D. C. B. Marsh, Renate McLaughlin, Lieselotte Miller, R. E. Moyer, P. V. Murty (India), C. B. A. Peck, Stanton Philipp, R. S. Ray, Simeon Reich (Israel), C. H. Sampson, P. A. Scheinok, Allan Wachs, Mitchell Wand, John Wessner, and the proposer.

A Locus Problem

E 1881 [1966, 411]. *Proposed by Omar Khayyam, Jr., University of California, Berkeley*

Describe the locus of a point P in the Euclidean plane for which there is a function f with the property that the graph of a function g defined on the whole real line is symmetric with respect to P if and only if g commutes with f (i.e., $f(g(x))=g(f(x))$ for all real x).

Solution by Daniel Marcus, Student, Adelphi University. For the point (a, b), $a\neq b$, it is necessary that f (assuming it exists) commute with $g_m(x)=m(x-a)+b$ for all real m, so that $f(g_m(x))=g_m(f(x))$, or

$$f(m(x-a)+b)=m(f(x)-a)+b \tag{1}$$

for all real x and all real m.

First suppose that $x=\alpha\neq a$ and take $m=(\alpha-b)/(\alpha-a)$. Then (1) reduces to $f(\alpha)=\alpha$, $\alpha\neq a$. Now take $x=a+1$ and $m=a-b$, and (1) reduces to $f(a)=a$. This means that f must be the identity function, which commutes with every function, even those without symmetric graphs. Hence if $a\neq b$, there is no f with the desired property.

Now suppose that the graph of $g(x)$ is symmetric about the point (a, a), so that $g(x)=2a-g(2a-x)$ for all real x. Then take $f(x)=2a-x$, which gives $f(g(x))=g(2a-x)=g(f(x))$.

Conversely, suppose that $f(g(x))=g(f(x))$, so that, if $f(x)=2a-x$, we have $2a-g(x)=g(2a-x)$, which implies symmetry. Thus $f(x)=2a-x$ has the desired property for the point (a, a).

The locus of points for which such a function exists is the line $y=x$.

Square Roots of Unit Matrix

E 1882 [1966, 411]. *Proposed by W. C. Beckham, Kirtland Air Force Base*

Let I represent the $n\times n$ unit matrix. A is an $n\times n$ matrix which has only one nonzero entry in each row and column, these nonzero entries being either 1 or -1. If $A^2=I$, determine the number of ways there are of writing A.

I. *Solution by D. P. Roselle, University of Maryland.* Call the matrix $A=(a_{ij})$ *admissible* if it satisfies the conditions stated. It is clear from the row by column rule of multiplication that an admissible matrix is symmetric. Thus, if $\phi(n)$ denotes the number of admissible $n\times n$ matrices, then

$$\phi(n+1)=2\phi(n)+2n\phi(n-1), \qquad n\geq 1,$$

as follows if we first set $a_{11}=\pm 1$ and then $a_{1k}=\pm 1$ $(2\leq k\leq n+1)$.

Using the initial values $\phi(0)=1$, $\phi(1)=2$, we find that

$$\phi(n)=n!\sum 2^k/k!r!$$

where the summation extends over those nonnegative integers k and r which satisfy $k+2r=n$.

II. *Solution by Daniel Marcus, student, Adelphi University.* From the given conditions it is clear that A must be symmetric. Aside from the possibility of either of two nonzero entries, this problem is identical to E 1759 [1966, 413], the solution of which states that there are

$$\sum_{k=0}^{[\frac{1}{2}n]} \binom{n}{2k} \frac{(2k)!}{2^k k!}$$

ways of placing n rooks on an $n \times n$ chessboard so that no rook can take any other, and so that they are placed symmetrically about a given diagonal.

The necessary trivial modification is to multiply each term in the summation by 2^{n-k}, $n-k$ being the number of choices for positive or negative one, when there are $2k$ nonzero entries off the main diagonal. Hence the number of ways of writing A is

$$\sum_{k=0}^{[\frac{1}{2}n]} \binom{n}{2k} \frac{(2k)!2^{n-2k}}{k!}.$$

Also solved by J. C. Abad, J. A. Carpenter & J. D. Fulton, R. B. Eggleton (Australia), Scott Harrod, Donald Jeffords, Erwin Just, E. S. Langford, Norman Locksley, D. C. B. Marsh, Norman Miller, Robert Patenaude (Germany), C. B. A. Peck, Stanton Philipp, B. V. Rao & M. N. Sastry (India), Bernard Rosner, Steven Russ, Sidney Spital, E. T. Wong and the proposer.

Solvers wrote the final formula in a number of different, equivalent ways. Marsh gives it in the form

$$\phi(n) = \frac{d^n}{dx^n}(e^{x^2+2x})\Big]_{x=0}.$$

A Generalization of the μ-function

E 1883 [1966, 411]. *Proposed by A. M. Vaidya, Texas Technological College*

The Möbius function $\mu(n)$ provides a criterion for deciding whether or not a given integer is squarefree. Find a function (in terms of μ) which has different constant values for primes, for composite squarefree integers, and for other integers.

I. *Solution by H. S. Hahn, Pennsylvania State University.* Such a function is given by

$$\phi(n) = \prod_{d|n} \mu(d), \qquad n > 1,$$

which is -1 if n is prime, 0 if n has a squared factor, and $+1$ if n is a squarefree composite. We explain the last part.

Suppose n is a product of $k(>1)$ distinct primes. Then the number of divisors

of n with j primes is $\binom{k}{j}$ and, for each such divisor d, $\mu(d)=(-1)^j$. Thus $\phi(n)=(-1)^{\alpha(k)}=+1$, where

$$\alpha(k)=\sum_{j=1}^{k}\binom{k}{j}j=k\sum_{j=1}^{k}\binom{k-1}{j-1}=k\cdot 2^{k-1},\ \text{which is even.}$$

II. *Solution by R. B. Eggleton, Avondale College, Cooranbong, N.S.W., Australia*

The function defined below meets the requirements. Let $p_1, p_2, \cdots, p_r$ be the distinct primes which do not exceed $\sqrt{n}$. Then

$$\mu(n)=\begin{cases}(-1)^s & \text{if } n \text{ is squarefree and has } s \text{ distinct prime factors}\\ 0 & \text{if } n \text{ is not squarefree.}\end{cases}$$

$$\mu(p_1p_2\cdots p_rn)=\begin{cases}(-1)^{r+1} & \text{if } n \text{ is prime}\\ 0 & \text{if } n \text{ is composite.}\end{cases}$$

Thus $\mu^*(n)\equiv|\mu(n)|+|\mu(p_1p_2\cdots p_rn)|$ is 2 if n is prime, 1 if n is composite and squarefree, and 0 otherwise.

Also solved by Gabriel Bastien, M. G. Greening (Australia), F. T. Howard, Donald Jeffords, Daniel Marcus, D. C. B. Marsh, Lieselotte Miller, and Charles Wells.

Convergence of a series

E 1884 [1966, 411]. *Proposed by A. F. Beardon, University of Maryland*

Prove that the series

$$\sum_{n_1,\cdots,n_k=1}^{\infty}\frac{1}{(n_1^2+\cdots+n_k^2)^p}$$

converges if and only if $p>k/2$.

I. *Solution by Yu Chang and Sidney Spital, California State Polytechnic College.* The sufficiency part of the proof follows almost directly from the arithmetic mean-geometric mean inequality, $n_1^2+\cdots+n_k^2\geqq k(n_1\cdots n_k)^{2/k}$. Hence, denoting the given series by $S(p)$,

$$S(p)<\frac{1}{k}\left(\sum_{n_1=1}^{\infty}n_1^{-2p/k}\right)\cdots\left(\sum_{n_k=1}^{\infty}n_k^{-2p/k}\right).$$

For $2p/k>1$, each factor on the right converges, therefore so too must $S(p)$.

It suffices to demonstrate the necessity part for $p=k/2$. This is begun with $n_1^2+\cdots+n_k^2<(n_1+\cdots+n_k)^2$ and followed by a diagonal rearrangement of the resulting series. Namely,

$$S(k/2)>\sum_{m=k}^{\infty}s(m),\qquad s(m)=\sum_{n_1+\cdots+n_k=m}1/m^k$$

and this is a finite sum. But the number of solutions of $n_1+\cdots+n_k=m$, in positive integers, is $\binom{m-1}{k-1}$. Hence

$$S\left(\frac{k}{2}\right) > \frac{1}{(k-1)!}\sum_{m=k}^{\infty}\left(\frac{m-1}{m}\right)\cdots\left(\frac{m-k+1}{m}\right)\frac{1}{m}.$$

Each of the first $k-1$ factors within the summation tends to one for m large; therefore divergence of $S(k/2)$ follows from a comparison with the harmonic series.

II. *Solution by M. S. Klamkin, Ford Scientific Laboratory.* By the integral test (for m-dimensions) the series will converge or diverge with the integral

$$\int_1^{\infty}\int_1^{\infty}\cdots\int_1^{\infty}\frac{dn_1dn_2\cdots dn_k}{(n_1^2+n_2^2+\cdots+n_k^2)^p}$$

or equivalently (using spherical coordinates) with the integral $\int_c^{\infty}(r^{k-1}dr)/r^{2p}$, which converges if and only if $2p-k+1>1$, or $p>k/2$.

We are assuming p is a constant, otherwise the result is not valid, i.e. $\sum_{n=1}^{\infty} n^{1+1/n}$ diverges.

Also solved by E. S. Langford, J. Lehner, D. E. Nixon, M. Shiba (Japan), and Al Somayajulu.

A Triangle Inequality

E 1887 [1966, 538]. *Proposed by Simeon Reich, Haifa, Israel*

Let I, O, H, M, respectively, denote the incenter, circumcenter, orthocenter, and centroid of an acute-angled triangle ABC. Show that

$$9\frac{AM^2+BM^2+CM^2}{AO^2+BO^2+CO^2}-\frac{AH\cdot BH\cdot CH}{AI\cdot BI\cdot CI}\geqq 8,$$

with equality if and only if the triangle is equilateral.

Solution by Leon Bankoff, Los Angeles, California. The given expression can be transformed into $\Pi\sin^2(\frac{1}{2}A)\leqq 1/64$ by making the following substitutions (see Roger A. Johnson, *Advanced Euclidean Geometry*, pp. 163, 174, 186, 191):

(1) $AO^2+BO^2+CO^2=3R^2$,

(2) $AM^2+BM^2+CM^2=3(R^2-OM^2)$,

(3) $AH\cdot BH\cdot CH=8R^3\Pi\cos A$,

(4) $AI\cdot BI\cdot CI=64R^3\Pi\sin^2(\frac{1}{2}A)$,

(5) $9OM^2=(3OM)^2=OH^2=R^2(1-8\Pi\cos A)$.

Since it is known that $\Pi\sin(\frac{1}{2}A)\leqq 1/8$, with equality only when $A=B=C$, the result follows.

Also solved by A. N. Aheart, M. G. Greening (Australia), J. M. Quoniam (France), K. R. Rajagopalan (India), R. Sivaramakrishnan (India), C. S. Venkataraman (India), and the proposer.

Sum of the Divisors of an Integer

E 1888 [1966, 538]. *Proposed by C. C. Lindner, Coker College, Hartsville, N. C.*

Prove that if $n>2$, then $\sigma(n)\leqq n\sqrt{n}$, where $\sigma(n)$ is the sum of divisors of n.

I *Solution by Anders Bager, Hjørring, Denmark.* Put $f(n)=\sigma(n)/n$. We shall prove that $f(n)<\sqrt{n}$ for all $n\geqq 3$. As the general case follows easily by multiplicativity, we need only consider the following three special cases:

1) $n=2^\alpha$, $\alpha\geqq 2$. $f(n)<2\leqq 2^{\alpha/2}=\sqrt{n}$.
2) $n=p^\alpha$, p odd prime. $f(n)<1/(1-1/n)\leqq 1/(1-1/3)=3/2<\sqrt{3}\leqq\sqrt{n}$.
3) $n=2p^\alpha$, p odd prime. $f(n)<\frac{3}{2}/(1-\frac{1}{3})=\frac{9}{4}<\sqrt{6}\leqq\sqrt{n}$.

II. *Solution by Steven Russ, Rice University.* To be a divisor of n, m can be only one of $n, n/2, n/3, \cdots, n/n$ (and certainly not all of these are integral for $n>2$). So $\sigma(n)\leqq n\sum_{k=1}^{n}1/k<n(1+\log n)$.

For $n>20$, $1+\log n<n^{1/2}$, which proves the problem for $n>20$. For the integers $2<n\leqq 20$, a numerical check is easily made.

By the same method it can be shown for every $\epsilon>0$, there exists a sufficiently large N such that if $n>N$, $\sigma(n)\leqq n^{1+\epsilon}$, namely N is such that $\log N\leqq N^\epsilon$.

Is it possible to find a Hamel basis of the real numbers over the rational numbers which is closed under ordinary multiplication of real numbers?

5539. *Proposed by Robert Breusch, Amherst College*

Find all the continuous, nonnegative-valued, strictly increasing functions f, defined for $x \geqq 0$, such that for all $x \geqq 0$,

$$f(f(x)) = k^2x, \quad \text{with} \quad k > 1.$$

Also solved by J. Aczel, J. P. Celenza, Robert Cohen, G. Di Antonio, E. J. Eckert, Robert Goldstein (England), D. A. Hejhal, H. E. Lahmann (Germany), Dorembus Leonard (Israel), M. D. Mavinkurve (India), Charles McCracken, Jürg Rätz (Switzerland), and the proposers.

Goldstein generalizes by replacing (2) with the condition $f(g(x))=h(f(x))$, where h is bounded above (or below) and the range of g contains an interval of length greater than unity. He also refers to R. P. Boas, *A Primer of Real Functions*, p. 111 for other results of the same nature. For a further generalization, Aczel and Rätz refer to S. Kurepa, *Note on Additive Functions*, Glasnik Mat.-Fiz. Astr., 20 (1965) pp. 75–78. Cohen, with his solution, raises the question as to the possibility of replacing p in (2) by g, an entire transcendental function.

Roots of Transfinite Ordinals

5431 [1966, 1018]. *Proposed by G. F. Schumm, University of Chicago*

Given the ordinal numbers ξ and γ, we call ξ a root of γ if there exists an ordinal number $\alpha>1$ such that $\xi^\alpha=\gamma$. What is the kth smallest transfinite number for which there exists no root of degree >1?

I. *Solution by K. A. Bowen, Princeton University.* We first note the following simple facts: if $1\leqq m<\omega$ and $1<n<\omega$, then $n^m<\omega$ and $n^\omega=\omega$. Moreover, if α is a limit number so is n^α. Hence if $\alpha\geqq\omega$, then $n^\alpha=\omega$ or $n^\alpha=\omega\cdot 2$ according as $\alpha=\omega$ or $\alpha>\omega$.

Finally, if $0\leqq n$, $m<\omega$, $(\omega+m)(\omega+n)\geqq\omega\cdot\omega=\omega^2$. Hence we see that if $1\leqq s<\omega$, $\omega+s$ has no roots of degree >1, while if $1<n<\omega$, n is a root of ω. Thus the kth transfinite "prime" is $\omega+k$.

II. *Additional Comments by Leonard Gillman, University of Rochester.* It is easy to continue the enumeration up to ω^2; but shortly thereafter, it gets complicated. Between ω and ω^2, the only numbers with roots are limit numbers. In general, the transfinite ordinals having roots are precisely those of the form

$$(1)\qquad \omega^\beta\cdot k\ (\beta>0;\ 0<k<\omega)\qquad \text{or}\qquad (2)\qquad \mu^\nu(\mu+m)^n,$$

where

$$(2')\qquad (\mu+m)^n=\mu^n+\mu^{n-1}\cdot m+\cdots+\mu\cdot m+m$$

(μ a limit ordinal, ν a limit ordinal or 0, $n<\omega$, $\nu+n>1$, and $m<\omega$).

The numbers (1) are the powers of finite ordinals: since $k_1^\omega=\omega$ for $1<k_1<\omega$, we have

$$\omega^\beta\cdot k=(k_1^\omega)^\beta\cdot k=k_1^{\omega\beta+k_2}\qquad (k=k_1^{k_2},\ k_1>1,\ k_2\geqq 0).$$

The numbers (2) are the powers of transfinite ordinals: $(\mu+m)^{\nu+n}$ reduces to (2), since $(\mu+m)^\nu=\mu^\nu$; and (2′) is established by induction on n, with the help of the relation $\mu^{n-1}\cdot m+\mu^n=\mu^n$ $(n>0)$. For necessary and sufficient conditions of ξ and γ in order that ξ be a root of γ, see P. W. Carruth, *Roots and Factors of Ordinals*, Proc. Amer. Math. Soc., 1 (1950) 470–480; Math. Reviews, 12 (1951) 166.

Also solved by the proposer.

An Orthogonal Sequence

5433 [1966, 1019]. *Proposed by Benjamin Volk, Yeshiva University*

Let ϕ be a function, continuous on $(0, 1]$ of period 1 and satisfying

$$\sum_{j=1}^{n} \phi\left(x + \frac{j-1}{n}\right) = 0, \qquad n = 1, 2, \cdots.$$

Then the sequence $\{\phi(n!\,x)\}$ is orthogonal on $(0, 1)$. (Cf. 5143 [1964, 1050].)

Solution by L. Carlitz, Duke University. The hypothesis should read $\sum\phi(x+(j-1)/n)=0$, $(n=2, 3, \cdots)$. Let $m<n$ and put $k=n!/m!$. Then

$$\begin{aligned}
\int_0^1 \phi(m!x)\phi(n!x)\,dx &= \frac{1}{n!}\int_0^{n!} \phi\left(\frac{1}{k}\,x\right)\phi(x)\,dx \\
&= \frac{1}{n!}\int_0^1 \phi(x) \sum_{j=0}^{n!-1} \phi\left(\frac{x+j}{k}\right) dx \\
&= \frac{1}{n!}\int_0^1 \phi(x) \sum_{r=0}^{m!-1} \sum_{s=0}^{k-1} \phi\left(\frac{x+rk+s}{k}\right) dx \\
&= \frac{m!}{n!}\int_0^1 \phi(x) \sum_{s=0}^{k-1} \phi\left(\frac{x+s}{k}\right) dx = 0.
\end{aligned}$$

Also solved by M. D. Mavinkurve (India).

Orthogonal Projections from a Normal Matrix

5434 [1966, 1019]. *Proposed by H. Kestleman, University College, London, England*

Let N be a normal $n\times n$ matrix (i.e. N commutes with its Hermitian transpose), $N^k=I$ for some integer $k\geqq 2$, and $N\neq I$. If $M=(1/k)\cdot(I+N+N^2+\cdots+N^{k-1})$ and $M\neq 0$, show that M projects orthogonally on to a subspace of complex-euclidean n-space, and identify this subspace in relation to N. (Note that if $n=k=2$, then N is a reflection and $\frac{1}{2}(I+N)$ is the projection onto the mirror.)

Solution by G. M. Leibowitz, Northwestern University. By the spectral theorem, $N=\sum\lambda_i E_i$ where the λ_i are the distinct eigenvalues of N and the E_i are mutually orthogonal self-adjoint projections. So $p(N)=\sum p(\lambda_i)E_i$ for every complex polynomial p. In particular, $M=p_0(N)$ where

$$p_0(\lambda) = \frac{1}{k}\sum_{j=0}^{k-1}\lambda^j = \begin{cases} 1 & \text{if } \lambda = 1 \\ \dfrac{1}{k}\,\dfrac{1-\lambda^k}{1-\lambda} & \text{if } \lambda \neq 1, \end{cases}$$

so that $M=\sum p_0(\lambda_i)E_i$. Since $N^k=I$, $\lambda_i^k=1$ for each i. If all $\lambda_i\neq 1$, $p_0(\lambda_i)=0$ for all i, so $M=0$. Otherwise, some $\lambda_j=1$ and so $p_0(\lambda_i)=\delta_{ij}$; thus $M=E_j$. In

either case, M is a self-adjoint projection.

We note (i) The assumption of finite dimensionality is unnecessary. For $N=\int\lambda dE(\lambda)$ where the integral extends over the spectrum of N. If $N^k=I$ then $\{1\}=\sigma(I)=\sigma(N^k)=\sigma(N)^k$, so $\sigma(N)$ is contained in the set of kth roots of unity. Thus the measure $E(\cdot)$ is supported on that set, and so $N=\sum\lambda_iE_i$ with the λ_i all the kth roots of unity (some of the projections E_i may be 0).

(ii) The range of M is $\{x: Nx=x\}$, the set of invariant elements for N. For if $Nx=x$, then $N^jx=x$ for each j, so $Mx=(1/k)\sum N^jx=x$. Conversely, $NM=(1/k)\sum_{j=1}^{k-1}N^{j+1}=M$ since $N^k=I$, so if $Mx=x$, $Nx=NMx=Mx=x$.

(iii) We can generalize in the following way: Suppose $p(\lambda)=(\lambda-\lambda_0)q(\lambda)$ with p, q polynomials and $q(\lambda_0)=1$. If N is a normal operator and $p(N)=0$, then $q(N)$ is the projection onto the null space of $N-\lambda_0I$.

Also solved by D. W. Bailey, J. P. Celenza, John de Pillis, D. Ž. Djoković (Yugoslavia), W. G. Dotson, Jr., Harley Flanders, A. S. Householder, C. M. Joiner & S. J. Pierce, C. R. MacCluer, M. D. Mavinkurve (India), G. W. Soules, Art Steger, R. C. Thompson, and the proposer.

Norm of Complex Homomorphisms on a Commutative Banach Algebra

5435 [1966, 1019]. *Proposed by J. P. Williams, University of Michigan*

In the appendix to his book, *Fourier Analysis on Groups*, (Interscience, 1962), W. Rudin asserts that if A is a commutative Banach algebra then each nonzero complex homomorphism on A has norm 1. Is this true in general?

I. *Solution by Chi Song Wong, University of Illinois.* It is not true. Let D be the closed unit disc of the complex plane K and let $A(D)$ be the disc algebra. Consider the Banach subalgebra of $A(D)$:

$$B = \{f \in A(D): f(0) = 0\}.$$

Let t_1, t_2 be any elements in K such that $0<|t_1|<1$, $|t_2|=1$, and take multiplicative linear functionals h_1, h_2 on B such that for any $f\in B$

$$h_i(f) = f(t_i), \qquad i = 1, 2.$$

It is familiar that $\|h_i\|\leqq 1$, $i=1, 2$. For any nonzero f in B, f is not a constant, so by the maximum modulus principle, $|f(t_1)|\neq\|f\|$. Therefore $\|h_1\|<1$. On the other hand, let f be the function on D defined by

$$f(z) = \tfrac{1}{2}z(z + t_2), \qquad z \in D.$$

Then $f\in B$ and $\|f\|=1$. Thus $\|h_2\|\geqq|h_2(f)|=|f(t_2)|=1$ and therefore $\|h_2\|=1$.

II. *Solution by John Rainwater, University of Washington.* The assertion is not generally true. Let A be any normed algebra without a unit, and with norm $x\to\|x\|$. Let K be a real number greater than 1. The mapping $x\to K\|x\|$ is an algebra norm on A for which all multiplicative linear functionals have norm not exceeding $1/K$. This example also proves that a homomorphism of a commutative Banach algebra into a semisimple Banach algebra can have arbitrarily small norm. (See Theorem in D5 of Rudin, *loc. cit.*, p. 263.)

Also solved by G. M. Leibowitz, and the proposer.

A counterexample to Rudin's statement occurs in A. Wilansky's *Functional Analysis*, p. 278, Problems 2 and 3.

Some Trigonometric Integrals

5438 [1966, 1020]. *Proposed by M. L. Glasser, Battelle Memorial Institute*

Express the following integral in terms of Fresnel functions:

$$\int_0^\infty e^{x \sin y} \sin\left\{x \cos y \pm \tfrac{1}{2}(y + n\pi)\right\} dy.$$

Solution by Lowell Schoenfeld, Pennsylvania State University. The integrals as printed diverge. To show this, let λ be $+1$ or -1; then the integrals in question are given by

$$\int_0^\infty e^{x \sin y} \sin\left\{x \cos y + \tfrac{1}{2}\lambda(y + n\pi)\right\} dy. \tag{1}$$

Let $I_m(\alpha, \beta)$ be the integral which results when the integration limits 0 and ∞ are replaced by $2\pi(2m+\alpha)$ and $2\pi(2m+\beta)$ respectively. The divergence of (1) is a consequence of the following fact which we demonstrate: For fixed values of λ, x, n there correspond numbers α, β, η which are independent of m, $0 \leqq \alpha < \beta$ and $\eta > 0$, and are such that for all integers m we have $|I_m(\alpha, \beta)| \geqq \eta$.

On making the substitution $u = (y - 4\pi m)/2\pi$, we obtain, for integral m,

$$I_m(\alpha, \beta) = 2\pi \int_\alpha^\beta f(u) e^{x \sin 2\pi u} du,$$

where $f(u) = \sin(x \cos 2\pi u + \lambda\pi u + \frac{1}{2}\lambda n\pi)$. (Note that $f(u)$ and the last integral are independent of m.) If $x + \frac{1}{2}\lambda n\pi$ is not an integral multiple of π, we define $\alpha = 0$ and find that $f(\alpha) = \sin(x + \frac{1}{2}\lambda n\pi) \neq 0$. If $x + \frac{1}{2}\lambda n\pi = k\pi$, where k is an integer, then we define $\alpha = \frac{1}{2}$ and find that

$$f(\alpha) = f(\tfrac{1}{2}) = \sin\left\{(\lambda n - k)\pi + \tfrac{1}{2}\lambda\pi\right\} = \pm 1 \neq 0.$$

In either case, $f(\alpha) \neq 0$. By continuity, there exists $\beta > \alpha$ such that for all $u \in [\alpha, \beta]$, $f(u)$ has the same sign as $f(\alpha)$, and $|f(u)| \geqq \frac{1}{2}|f(\alpha)|$. Hence

$$\begin{aligned} |I_m(\alpha, \beta)| &= 2\pi \int_\alpha^\beta |f(u)| e^{x \sin 2\pi u} du \\ &\geqq \pi(\beta - \alpha) |f(\alpha)| e^{-|x|} \equiv \eta, \end{aligned}$$

as we set out to prove.

Editorial Note. Through an unfortunate corruption in the typescript, the integrals came through with an infinite limit whereas the proposer intended integrals with finite limits:

$$\int_0^\pi e^{x \sin y} \sin\left\{x \cos y \pm \tfrac{1}{2}(y + n\pi)\right\} dy \tag{2}$$

which are expressible in terms of the Fresnel integrals. Further contributions for the evaluation and representation of the integrals in (2) will be welcomed and are now solicited.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto 5, Canada, Correspondence about reviews is welcomed.

Non-Standard Analysis. By A. Robinson. Edited by L. E. J. Brouwer, A. Heyting. A. Robinson and P. Suppes. North Holland, Amsterdam, 1966. xi+293 pp. $10.00.

Ideas developed in the study of the foundations of mathematics, notably those of set theory, have been applied increasingly in most branches of modern mathematics. Professor Robinson has been a pioneer in a new field: the direct application of the central ideas of metamathematics, the study of proof theory, to algebra. The present work is an application of these ideas to analysis, and also to applied mathematics, and it is even more remarkable; firstly, in view of the lesser role that axiomatics plays in these subjects, in showing that metamathematics is so fruitful a tool in their study, and secondly, in that it combines these very modern methods with a rigorous revival of the use of the oldest method of analysis, that of infinitesimals.

The central idea of the book is a method by which any mathematical system can be imbedded in a larger system in such a way that all statements true in the original system remain true, provided that they are interpreted in a certain manner, in the extended system. When this construction is applied to the real numbers it produces a system containing, in addition to the ordinary real numbers, elements which we would recognize as infinitely large or infinitesimal, though from the point of view of the new system they obey all the laws to which the real numbers are subjected. Because the interpretation of these laws involves certain restrictions on the interpretation of terms such as "set," these systems are called nonstandard models of the real numbers.

The way in which such systems are constructed is described in the central second chapter of the book, which is, unfortunately, by far the most difficult. Some of the difficulty involved is inevitable in the very abstract subject matter, but it is increased by a sparseness of explanation which makes great demands on any reader not acquainted with metamathematical theory on the one hand and on the theory of ultrafilters on the other. These difficulties are further increased by a rather large number of misprints and similar mistakes. The reader qualified to follow this chapter or even to take its results for granted and press on (a feasible method of reading this book, and perhaps to be recommended for the non-logician on his first reading) will find the later chapters considerably easier going and very rewarding. They show in detail how infinitesimals and infinitely large numbers can be applied in the calculus, topology, the theory of groups and linear spaces and in certain parts of applied mathematics, such as boundary layer theory or St. Venant's Principle.

Many of these arguments are on lines which one might more or less expect once one accepts that the use of infinitesimals and infinitely large integers is legitimate, but there are others which indicate that a powerful new method has been added to analysis. In particular one may mention a problem on invariant subspaces of operators, which was

first solved by the methods of nonstandard analysis, and the ingenious applications to the theory of functions of a complex variable.

The last chapter contains observations on the history of the calculus. These have already been reviewed in this MONTHLY (May 1966, p. 608). One need say only that they show the greater flexibility in interpretation of the sometimes elliptical statements of the great mathematicians of the past which is provided by the existence of new mathematical models in terms of which their words can be understood.

This is certainly a most important and pathbreaking work. It is to be hoped that the author will find time to rewrite the second chapter so as to make it accessible to a wider circle of readers. In any case it should prove of value to very many mathematicians by showing them, as practically no other work that I know of can do, the significance to mathematics and the meaning of the concepts of metamathematics.

J. L. B. COOPER, University of Toronto and Chelsea College of Science and Technology, University of London.

Introduction to Algebra. By Sam Perlis. Blaisdell, Waltham, Mass., 1966. xx+440 pp. $9.75.

(A review based on classroom use.)

In the past few years there have appeared a number of abstract algebra texts intended for a first course and containing advanced topics, e.g., the Sylow Theorems and Galois Theory, but only a little linear algebra. Of course, the trend today is toward the introduction of linear algebra into the calculus sequence, but until this is universally done, the effectiveness of these books as first course algebra texts is greatly reduced. Indeed, linear algebra would not be available to motivate and illustrate other algebraic structures and the students would miss the experience of learning to construct proofs in the more concrete situations of linear algebra. Perlis' book, on the other hand, goes in the opposite direction. Many of the advanced topics are omitted in order to leave room for an integrated treatment of linear and abstract algebra, presuming no previous work in algebra.

Perlis' book is intended for a year's course in algebra, but it is flexible enough to be suitable for a semester course in abstract algebra or a semester course in linear algebra. It covers linear algebra, first with n-tuple spaces and later with abstract spaces, and goes through the reduction to diagonal form of real symmetric matrices. More advanced topics, like the Jordan canonical form, are not included. Group theory does not include homomorphisms, except for a few exercises, but homomorphisms, ideals, and residue class rings are studied in ring theory. There is an excellent chapter on divisibility for integers and for polynomials, with principal ideals used as a unifying device. The discussion of polynomials is very detailed and there is a chapter on classical algebra, containing results on multiplicities of roots and irreducibility of polynomials over the rational, real, and complex fields. The chapter on field extensions contains a proof of the impossibility of the trisection of an angle.

In using this book for a year's course, I modified the order to take up group theory and all the linear algebra before covering the material on rings and fields. I found that there is more in the book than can be covered in a year, but this arrangement allowed the class to cover linear algebra thoroughly.The problems are excellent; there are many nonroutine but workable problems that can be assigned to the better students and also enough routine ones for the poorer students. The writing is clear and detailed; many sections are suitable for self-study. There are very few misprints or errors. The only serious source of confusion I found was with formula 14.43 on p. 411, which is true only for symmetric matrices.

In summary, I regard this as an outstanding textbook, well-planned and well-written.

I recommend it, in particular, for a first course in algebra where there has been no previous work in linear algebra.

R. B. REISEL, Loyola University, Chicago

Abstract Theory of Groups. By O. U. Schmidt. Translated from the Russian by Fred Holling and J. B. Roberts. Edited by J. B. Roberts. Freeman, San Francisco, 1966. vi+174 pp. $5.00.

In 1916 when this book was written it admirably fulfilled the purpose of supplying an introductory text in group theory in Russian. However, very few books in mathematics can hope to survive for half a century and the current translation is primarily of historical interest. I would not recommend this book to a beginner in the subject as many things in group theory have been clarified since 1916. The most striking example of this is the concept of a homomorphism, which as defined in the text need not even be a function. Also some of the terminology used here sounds strange to modern ears. For instance "special" is used in place of "nilpotent" and "group union of" in place of "group generated by." (The latter is due to the translators. According to a footnote, Schmidt had used "least common multiple of.") The main impression I received on reading the book is that mathematics progresses and many things that appear difficult to one generation may become elementary for the next.

WALTER FEIT, Yale University

Vector Spaces. By D. A. Raikov. Translated from the Russian by Leo F. Boron, with the assistance of H. R. Stevens and G. F. Votruba. Noordhoff, Groningen, 1965. xii+190 pp. $7.60.

This book is an algebraic introduction to the theory of topological linear spaces, and consists of three chapters: Preliminary information about partially ordered sets and about groups, General theory of vector spaces, L-spaces. The first two chapters take up about two-thirds of the book, and give a masterly account of the general theory of vector spaces. The last section of the second chapter is devoted to a discussion, in algebraic form, of the Hahn-Banach theorem concerning the extension of a linear function. In the final chapter the L-spaces which were first introduced by the author, are considered. These spaces are essentially the algebraic analogues of linear topological spaces. There is a detailed study of the algebraic analogues of many notions from the theory of topological linear spaces. The chapter ends with a study of L-spaces over the fields of real and complex numbers, and the algebraic analogue of the Krein-Milman theorem on extreme points of bicompact convex sets is proved. There is an index. There are no exercises, which is a pity.

DANIEL PEDOE, University of Minnesota

The Foundations of Intuitionistic Mathematics. By S. C. Kleene and R. E. Vesley. North-Holland Publishing Company, Amsterdam, 1965. 206 pp. $7.00.

This monograph on the foundations of intuitionistic mathematics has been long awaited. It reports on research that has been continuing for fifteen years; the research has been reported in various papers, particularly by the senior author, but this is the unified and definitive product of many years of work.

As might be expected, it is written from a formalistic and model-theoretic point of view. This is not as inappropriate as it sounds; even Heyting has formalized a fragment of intuitionist mathematics. As Kleene writes, "The formation rules and postulates help the outsider by separating out for him a relatively small number of concepts he must grasp, and of propositions and methods of inference to which he must assent, in order that in principle nothing else should remain problematical for him in the body of intuitionistic mathematics deducible within the system. (I need hardly add that the outsider often needs just this kind of help.) Furthermore, metamathematical investigations are made

possible, as well as investigations, which we may call model-theoretic or semantical, . . " (p. 6).

The book consists of four chapters. Chapter I, by Kleene (90 pp.), gives a formal system of intuitionistic analysis, and chapter III, by Vesley (40 pp.) extends this to include an intuitionistic theory of the continuum. Chapter II, by Kleene (43 pp.) provides several notions of *realizability*, helpful in developing relations between classical and intuitionistic analysis. (It should be observed that not only are there classical assertions that cannot be proved in intuitionistic systems, but that the converse holds as well: there are intuitionistic assertions that do not hold in classical mathematics.) This chapter is particularly interesting. Chapter IV, also by Kleene (23 pp.), deals with some problems of order in the continuum.

The style of the book is very much like that of Kleene's *Introduction to Metamathematics*, and the content is heavily dependent on that book. Most of the axioms of the formal system developed in the first chapter are to be found written out only in the earlier book. Having to look in a different book for the axioms of the system you are studying in one book would be very inconvenient, except that the ordinary reader will need to have Kleene's earlier book open on his desk the whole time he is reading the present book anyway. (Indeed, this monograph is, among other things, an excellent study work-book for *Introduction to Metamathematics*.) Nevertheless, the book constitutes a rich and accessible study of intuitionistic analysis.

H. E. KYBURG, JR., University of Rochester

Introduction to Linear Algebra. By Marvin Marcus and Henryk Minc. Macmillan, New York. Collier-Macmillan, London, 1965. x+261 pp. $7.95.

Here we have yet another text in linear algebra. Such a book must justify its publication by offering new, or otherwise unusual, material or pedagogical excellence. This text does indeed come up with some new ideas, although it is not entirely satisfactory.

The text is intended, according to the preface, for a one semester course for sophomores or juniors although the prerequisite is only the "successful completion" of a standard course in college algebra. The text belies this preparation in its level of sophistication.

There are three chapters entitled: Vector spaces and linear transformations; Linear equations and determinants; Characteristic roots. The text combines the matrix and linear transformation approach leaning somewhat more heavily on matrices. The material on determinants is fuller than one usually sees; the approach here is not through multilinear functions. The last chapter includes some interesting material on matrix inequalities. Here we find Gershgorin disks, the Courant-Fischer theorem and Cauchy's inequalities for characteristic roots of submatrices.

The style is somewhat thick and there are some confusing and difficult spots. For example: Definition 1.3 on pages 4 and 5, which includes some intercalary remarks, runs to 31 lines of type, almost a full page; bases are defined to be sets but are used as if they were ordered sets; fields are permitted to have 1 element; arbitrary rings sometimes mysteriously acquire identities.

The approach to the problems is the most unusual feature of the book. Each problem section includes true-false questions; solutions to all the problems, of which there are many, are to be found at the end of the text. Whether or not this is the best part of the book, or the worst, is up to the reader.

NEIL GRABOIS, Williams College

Handbook of Nonparametric Statistics, II. By John E. Walsh. Van Nostrand, Princeton, N. J., 1965. xxvi+686 pp. $17.50.

This is Volume II of a three volume set covering nonparametric statistics up to 1958.

Volume III has not yet appeared. The introductory chapter of Volume II states that "the first volume contains procedures for testing the random sample hypothesis, estimates and tests for expected values, estimates and tests for population percentiles, results for distribution-free tolerance regions, and procedures for investigating probability distributions."

Volume II contains seven chapters. Chapter I contains necessary information on how to use the handbook such as: notation, format, interpretation of "nonparametric" and some general remarks on nonparametric procedures. The format discussion needs careful study because in the remainder of the book the presentations of the various tests are written in a very abbreviated way requiring considerable decoding by the reader. Chapters II and III are concerned with the two sample problems for noncategorical and categorical data. Then follow two chapters on the several sample problem. The last two chapters include tests of symmetry and tests for extreme populations and observations. Each chapter and each section of each chapter begins with explanatory and introductory material. These introductions are followed by the highly coded "presentations." Some of the more lengthy "presentations" are so formidable in complexity that one would probably be better off going to the original literature. (A reference is included at the end of each "presentation.") The bibliography at the end of the book includes 339 titles, each one listing the pages on which it is cited in the Handbook. There is also both a very detailed subject index and an extensive table of contents (16 pages).

The handbook represents an enormous amount of work. Many important gaps found in the literature have been filled in by the author of the handbook. The handbook should prove valuable to both applied and mathematical statisticians, about to study a particular area, who wish a comprehensive review of the literature.

H. J. ARNOLD, Oakland University

Orthogonal Families of Analytic Functions. By Bernard Epstein. Macmillan, New York, 1965. viii+80 pp. $2.50 (paperback).

The study of Hilbert spaces whose elements are analytic functions has held the interest of many mathematicians, especially since the appearance of S. Bergman's works on kernel functions and conformal mapping. Some other topics of study have been zeros, interpolation, approximation, boundary behavior, and (more recently) relations between spaces of analytic functions and the general theory of linear operators.

In this monograph the author restricts his attention to the space $A_2(D)$ consisting of all analytic functions f on the bounded domain D in the plane for which $\int_D \int |f(z)|^2 dxdy < \infty$. Brief mention is also made of the Bergman class of antiderivatives of elements of $A_2(D)$ (i.e., all F such that $\int \int |F'(z)|^2 dxdy < \infty$). Omitted entirely are the Hardy class H^2 and the important classes of entire functions which are square integrable with respect to various weight functions. Kernel functions, conformal mapping, and interpolation problems are discussed.

The present work is a very brief introduction to the books of Bergman. Prerequisites are a knowledge of basic complex variables and linear algebra. No acquaintance with Hilbert space theory is required of the reader, and indeed Chapter 2 is a good concrete introduction to the rudiments of that theory. The presentation is pleasant and unhurried, and for the most part rigorous. Unfortunately there is a great deal of handwaving in the geometric parts of the chapter on conformal mapping (but perhaps this is an inherent weakness of the subject itself).

G. M. LEIBOWITZ, Northwestern University

Functional Analysis. By Kosaku Yoshida. Springer-Verlag, Berlin, 1965. xi+458 pp. $16.50.

Like many books with similar titles, the book under review contains a large cross

section of topics that go under the broad heading of functional analysis.

Topics include the basic facts on various topological vector spaces, generalized functions, uniform boundedness, closed graph theorem, interior mapping, Hormander's theorem on hypoelliptic partial differential operator, Hilbert spaces (including orthogonalization, the Riesz representation theorem and the Lax-Milgram theorem), the Hahn-Banach theorem, dual spaces, various topologies on the space of linear maps, strong and weak topologies, strong and weak measureability, vector valued analytic functions, the Gelfand-Mazur theorem, a wide class of results formally to be put under the title of 'distributions,' Fourier series of distributions, Mikusinksi's operational calculus, spectral theory, semigroups of operators (here one finds, perhaps for the first time in a book, an updated version of the theory of semigroups of operators presented by the author, who is a pioneer among students of this field), ergodic theory, integration of the equation of evolution, compact operators, normed rings and spectral representation, and vector lattices.

In the opinion of the reviewer the significant virtues of the book are (1) that a wide variety of topics is presented in a single book, and (2) the theory of semigroups of operators and their applications is given in a more general context than in earlier publications and covers the literature up to 1965. The author's style and presentation are very pleasing. The reader needs to be warned, however, that while the book certainly contains the basic material on spectral theory and also certain topics in topological vector spaces, it makes no claims of being devoted to these. A very exhaustive bibliography enhances the utility of the book. The book will long remain a useful reference and a text in a suitably planned graduate course.

M. S. RAMANUJAN, University of Michigan

Probability and Statistics. By H. Freudenthal. Elsevier, Amsterdam, London, New York, 1965. 139 pp. $5.00.

This book by Hans Freudenthal, Utrecht University, is a translation of the 1957 Dutch edition. It is quite different in format and flavor from the usual probability and statistics books.

The format is one of nine chapters broken up into curt, but precise, sections. The flavor, but not the accompanying wit, is possibly indicated by the following brief summary of Section 1.9.14; the section begins with the statement that it is possible for three stochastics (random variables) to be independent in pairs, but nevertheless interdependent. The example then given of this phenomenon is one of a hall lamp controlled, in a common manner, by a switch upstairs and a switch downstairs such that the lamp is off if both switches are "up" or "down" and on otherwise. The switches are used with equal frequency and the lamp burns half the day. Stochastics relating to the states of the switches and lamp turn out to be pairwise independent, but not fully independent.

The chapters of the book present in turn definitions and descriptions of the elements of probability, limit theorems, the classical distributions, Markov chains, estimation, significance and hypothesis testing, sequential analysis and game theory. There is also a discussion of the philosophical nature of probability. Frequently the chapters are highlighted by amusing illustrations and problems.

A disadvantage that this book may well prove to have with certain readers is that frequently nonstandard terminology is employed and at the same time few references to alternative sources are provided. This latter is especially sad in view of the fact that Freudenthal typically introduces a topic in an arousing manner, but does not develop it in any great detail.

The book would appear to be a good text for mathematics majors having to satisfy a statistics requirement or alternatively a good supplementary text, in a mathematical direction, for statistics students.

D. R. BRILLINGER, London School of Economics

The open mapping and closed graph theorems in topological vector spaces. By Taqdir Husain. Oxford Mathematical Monographs, 1965. x+106 pp. $4.80.

The two theorems named in the title of this monograph are related; they are amongst the most important and powerful results of functional analysis. Let E and F be two topological vector spaces (i.e., vector spaces provided with a topology under which the algebraic operations are continuous). A linear mapping f of E into F is called closed if its graph is closed in $E \times F$; the closed graph theorem asserts that, under certain conditions on E and F, every such closed linear mapping is continuous. One form of the open mapping theorem asserts that, again under suitable conditions on E and F, every closed linear mapping of E onto F is open, i.e., maps open sets onto open sets. First proved by Banach nearly thirty years ago under the hypothesis that E and F were complete metrizable spaces, these two theorems have received successive generalisations by various authors to wider classes of spaces.

The present book aims to collect together recent work on these two theorems and on related topics. In order to make it self-contained, the author has included two chapters of background material, containing a brief thirty-page summary of the theory of topological vector spaces. Then the book goes on to prove Banach's classical forms of the theorems, with some related results involving inductive limits. Chapters 4 and 5 deal with duality theory. The defining properties of several important classes of locally convex spaces can be given in terms of the so-called *ew** topology on the dual space (the finest coinciding with the weak* topology on equicontinuous sets). In particular, a space in whose dual every *ew**-closed subspace is weak*-closed is called B-complete, or fully complete. The important part played by these spaces in the study of the closed graph and open mapping theorems, first noticed by Ptâk, is expounded in these chapters. Finally, in the last two chapters, the author gives the contents of some of his own publications. These comprise the theory of a class of spaces called by the author S-spaces, in the duals of which the *ew** topology coincides with the topology of uniform convergence on precompact sets, and the theory of general classes of spaces which admit the closed graph theorem.

This is undoubtedly a specialist book, likely to be of interest to the reader who has some knowledge of the theory of topological vector spaces. In terminology and notation it follows fairly closely that of Bourbaki's tract. Its merit is that the contents of the author's papers, together with those of many other writers who have contributed to the subject, are available here, with a uniform style and notation, and compressed into about a hundred pages of print. The author offers some historical notes at the end, and there is also a bibliography.

A. P. ROBERTSON, University of Keele, England

Introduction to Algebra. By Donald J. Lewis. Harper and Row, New York, 1965. 318 pp. $8.50.

This is a book suitable for a two-semester course for able undergraduates. No previous acquaintance with abstract algebra is assumed (e.g., the book begins with a chapter on the integers) but the pace is brisk. A student of some ability who studies this book will gain much in mathematical sophistication as well as in knowledge of the basic concepts of algebra.

The number of topics covered is small, but each is treated in sufficient depth to make the concepts meaningful. Groups are studied through the structure of finite abelian groups. Rings, integral domains and fields are studied simultaneously, including some valuation theory and field extensions (but no Galois theory). The last chapter contains a fairly abstract treatment of vector spaces and linear transformations, with little mention of the geometric interpretations.

The author uses examples generously, for both illustration and motivation. For in-

stance, twenty pages are devoted to permutation groups before the study of group theory is begun. Exercises are numerous and varied in difficulty. On the whole, it appears to be a very teachable book.

In the preface, the author states that the original form of the book was a list of definitions, examples and theorems, used in a "prove-it-yourself" course. He states that it was thought that a book in that format would not meet with wide approval. and hence the present form. Perhaps such an "Aufgaben und Lehrsätze aus der Algebra" would not be widely used, but where used it would fill a real need. It is regrettable that this book could not have been made available in its original form as well as in the present form.

H. E. CHRESTENSON, Reed College

Quasilinearization and Nonlinear Boundary-Value Problems, vol 3. By R. E. Bellman and R. E. Kalaba. American Elsevier, New York, 1965. 224 pp. $8.50.

This book is a well written and well motivated introduction to quasilinearization and its applications to nonlinear boundary-value problems. A number of analytical concepts are introduced and illustrated through the use of simple nontrivial examples. The book begins with a discussion of the application of quasilinearization to the study of the Riccati equation. Here quasilinearization results in an explicit analytic representation for the solution in terms of quadratures and a maximum operation. This representation yields simple upper and lower bounds for the solution. In nonlinear two point boundary value problems the authors then show how quasilinearization may lead to a sequence of approximations with quadratic convergence. Chapter 3 examines conditions under which the sequence of approximations converges monotonically. Here the Green's function is encountered and its variation diminishing property emphasized. Chapter 5 deals with higher order equations and systems and develops techniques for using successive approximations without excessive reliance on rapid-access storage. Various methods for overcoming storage problems are discussed. Some nonlinear partial differential equations are dealt with in Chapter 5, and a number of examples are given in Chapter 6 which illustrate ways in which quasilinearization may be applied to treat various descriptive and variational processes. The final chapter illustrates how quasilinearization and dynamic programming may be effectively combined in the treatment of multi-dimensional variational problems, and identification problems. Computer programs for a number of problems are contained in the various appendices.

Each chapter begins with an introductory paragraph which motivates and describes the content of the chapter. The exposition is clear throughout, the references are numerous, and the misprints are few.

L. E. PAYNE, Cornell University

Begründung der euklidischen und nichteuklidischen Geometrien nach F. Klein, von László Rédei. Akadémiai Kiadó, Budapest, 1965. 363 pp. $10.00.

The first 227 pages of the book are devoted to a very careful construction of real projective space out of the Hilbert (nonprojective) axioms of incidence, order, and continuity. This construction uses some remarkable ideas such as construction of a further Desargues configuration from a given one, and a systematic use of central collineations to study the group of projectivities. After a representation of real projective space by homogeneous coordinates is obtained, the space is extended to complex projective geometry by one sentence. No geometric interpretation is offered. This is a pity in two respects. First, it contradicts the spirit of the book and makes questionable its synthetic approach. Second, a modern exposition of von Staudt's theory of conjugate complex elements over a real projective space would serve a great need, since it is carefully eliminated from all contemporary textbooks of projective geometry. Modulo the use of com-

plex numbers, and following Klein very strictly, the construction of the euclidean and noneuclidean groups proceeds in a very lucid way. The last chapter in which this is done can also serve as an illustration to chapter III of F. Bachmann's book (Aufbau der Geometrie aus dem Spiegelungsbegriff, Springer, Berlin, 1959). The formulas of all three geometries are quite complete, including Klein's formula for the euclidean distance as the square root of the product of two cross-ratios involving isotropic lines. As a development of geometry, the reviewer still prefers F. Schilling's book (Projektive und nichteuklidische Geometrie, 2 vols., Teubner, Leipzig und Berlin, 1931), from which he learned non-euclidean geometry.

H. GUGGENHEIMER, University of Minnesota

Principles of Hindu Reckoning. By Kūshyār Ibn Labbān. Translated by Martin Levey and Marvin Petruck. University of Wisconsin Press, Madison, 1965. xii+114 pp. $6.00.

This book will be of interest to persons with three types of concern for the history of mathematics. It will please the serious historical scholar as a careful translation and analysis, accompanied by a photostatic copy of the original manuscript, of a previously little known Arabic work. This may be the earliest work of this type (c. 1000 A.D.) since the only other copy of Kushyar's work is in Hebrew, and the still earlier works of Al Khowarizmi and others have come to us only in Latin translations. In this sense the book is a valuable contribution to the history of mathematics.

The person with a serious interest in the history of mathematics whose concern is more for the development and communication of ideas will also find the book interesting. He will probably feel, however, that it documents and reinforces much that he has known previously and adds little to our fund of knowledge and insights.

The teacher of the history of mathematics may find it a useful teaching device, as the reviewer has. The ideally extensive use which should be made of source materials is largely frustrated by language difficulties and lack of multiple copies of original documents. The reviewer cited this book to his class and asked them to decipher, explain, and interpret two problems copied from it for them. In doing this they "discovered" and finally understood why we write numerals "backward" today (Arabs still write from right to left), that sexagesimal fractions persisted long after the Babylonians, and that operations with them possess many of the advantages and follow the algorithms the students associate with decimals. This latter was especially brought out in the translators' association of Kushyar's rules for determining the place value of sexagesimally expressed products with modern rules for operations with exponents.

On the whole there were few errors, the introductory discussions and explanations were clear and the documentation will lead an interested reader a fine and merry chase.

Marshall Clagett correctly claims in his foreword to the book that "the reader will turn with greater perception to the medieval Latin arithmetics of the high and late Middle Ages."

P. S. JONES, University of Michigan

Algebra

Algebraic Groups and Discontinuous Subgroups. Proceedings of Symposia in Pure Mathematics, Volume IX. American Mathematical Society, 1966. vii+426 pp. $10.20.

" . . . A comprehensive exposition of the arithmetic aspect of algebraic groups." P, L.

The Theory of Spinors. By Elie Cartan. Foreword by Raymond Streater. M.I.T. Press, Cambridge, Mass., 1967. 157 pp. $7.00. A translation, first published in Paris in 1938, of notes on lectures by this great French mathematician. Rotations, reversals, multivectors, tensors, and spinors from a geometrical point of view. S, P, L.

A First Course in Abstract Algebra. By John B. Fraleigh. Addison-Wesley, Reading, Massachusetts, 1967. xvi+447 pp. $9.75. Intended as "a text from which an *average* student of mathematics" can benefit the most in a year course. Groups, rings, and fields are dealt with in forty-nine sections, reaching to such topics as algebraic extensions and homology groups. A subset of starred sections is designed to bring the student to Galois theory in a single semester. T(15—16).

Abstract Algebra. By Andrew O. Lindstrum, Jr. Holden-Day, San Francisco, 1967. xii+211 pp. $9.00. Sets, mappings, laws of composition, natural numbers, semigroups, equivalence relations, rational integers, groups, systems with more than one law of composition, polynomials, factorization, ideals, fields extensions, fields, linear mappings and matrices. Bourbaki terminology and logical symbols are used where appropriate. The book is based on classroom experience with four editions. T(16–17, year course).

Algebra. By Saunders MacLane and Garrett Birkhoff. Macmillan, New York, 1967. xix+598 pp. $11.95. This book is directed to the same audience as the authors' *Survey of Modern Algebra* which revolutionized undergraduate algebra following its publication in 1941. In order to present algebra for undergraduates on the basis of new insights and concepts, such as module, tensor product, category, and morphism, the authors have decided to make a "wholly new start." As in the previous book, abstract notions are developed from particular cases. Chapter headings are: Sets, Functions and Universal Elements, Integers, Groups, Rings, Special Fields, Modules, Vector Spaces, Matrices, Determinants and Tensor Products, Similar Matrices and Finite Abelian Groups, Quadratic Forms, Affine and Projective Spaces, Structure of Groups, Lattices, Categories and Adjoint Functors, Multilinear Algebra. Every textbook becomes obsolete in time, and it is to the credit of these authors that they decided to write a book that may well eliminate the use of their previous one. They even made it easy for us to distinguish the two by reversing the order of their names on the title page. T(15–17), S, P, L.

Varieties of Groups. By Hanna Neumann. Springer-Verlag, New York, 1967. viii+192 pp. $11.50. A "report" on a field that goes back to the 1930's but has developed for the most part since the 50's. P.

Abstract Algebra. By Chih-Han Sah. Academic, New York, 1967. xii+342 pp. $9.75. Preliminaries on set theory, from Peano's axioms to the rationals, groups, rings, integral domains, modules and associated algebras over commutative rings, vector spaces, fields, Galois theory, real and complex numbers. Pitched at a high level of abstraction, e.g. the determinant is defined, without any reference to matrices, in terms of the exterior algebra of a module over a commutative ring. T(16–17).

Applications

Optimal Control Theory, A Course in Automatic Control Theory. By R. Pallu de la Barriere. Translated by Scripta Technica. Edited by B. R. Gelbaum. Saunders, Philadelphia, 1967. xii+412 pp. $8.00. After mathematical prerequisites, the book deals

with linear servo systems, filtering, prediction, anticipation, discrete systems, programming, Markov control systems, minimum-time, and Pontryagin's principle. P.

Magneto-Fluid and Plasma Dynamics. Proceedings of Symposia in Applied Mathematics. Volume XVIII. American Mathematical Society, 1967. xii+294 pp. $6.80.

Seismic Love Waves. Z. S. Andrianova, V. I. Keilis-Borok, A. L. Levshin, and M. G. Neigauz. Translated from Russian by F. M. C. Goodspeed. Consultants Bureau, New York, 1967. xiv+91 pp. $15.00. The title is self-explanatory, but it should be remarked that the first and last authors are women and work at the Institute of Chemical Physics, while the two authors between are men and work at the Institute of Physics of the Earth. (The price is more than 15¢ per page!) P.

Spectral Theory and Wave Processes. Edited by M. Sh. Birman. Vol. I of Topics in Mathematical Physics. Translated from Russian. Consultants Bureau, New York, 1967. vii+114 pp. $15.00. The series is intended for "mathematicians specializing in the fields of mathematical physics, functional analysis, and the theory of differential equations." (The price is more than 13¢ a page!) P.

Applied Group Theory. By G. G. Hall. American Elsevier, New York, 1967. vii+128 pp. $6.00. "Applied" refers to physical applications. The emphasis is on "the theory of algebras" rather than "matrix representations." Topics include group algebra, character of groups, group representations and symmetry-adapted vectors, translation groups, continuous groups, rotation groups, product representations, and an appendix on connectivity. The author misspells Gordan. P.

The Advanced Theory of Language. By Gustav Herdan. Springer-Verlag, New York, 1966. xiii+495 pp. $14.00. A systematic treatise which includes portions of the author's more elementary *Language as Choice and Chance* (1956), now out of print. The author divides the subject of quantitative linguistics into four main branches: statistical linguistics, stylostatistics, optimal systems of language structure, and linguistic duality. The mathematical derivations appear in a systematic way in a final chapter of 75 pages. There are historical comments and bibliographies. This appears to be a significant contribution to a rapidly growing and very interesting field. P, L.

An Introduction to Mathematics for Students of Economics. By J. Parry Lewis. St. Martin's Press, New York, 1966. x+394 pp. $3.95 (paper). This is a paperback reprint of a book first published in 1959. It is slightly shorter and starts at a slightly lower level than *Mathematical Analysis for Economists*, by R. G. D. Allen, also available in paperback from the same publisher for $3.50. Both should be considered as possible textbooks or supplements in courses covering classical analysis. T, S, L.

Essentials of Statistics for Scientists and Technologists. By C. Mack. Plenum Press, New York, 1967. vii+174 pp. $5.95. For a low level service course. T.

Mathematics for the Physical Sciences. By Laurent Schwartz. Addison-Wesley, Reading, Mass., 1966. 358 pp. $14.00. An expanded and revised translation of the French original. After preliminary results in calculus it has chapters on elementary theory of distributions, convolution, Fourier series, the Fourier transform, the Laplace transform, the wave and heat conduction equations, the gamma function, and Bessel functions. There are exercises at the end of each chapter. Prerequisites include some linear algebra and functions of a complex variable. T(16), S, P.

Linear and Convex Programming. By S. I. Zukhovitskiy and L. I. Avadeyeva. Translated by Scripta Technica, edited by B. R. Gelbaum. Saunders, Philadelphia, 1966. viii+286 pp. $8.00. The editor's description, "a happy combination of mathematical

rigor, patient exposition and a wide variety of illustrative material" appears to be justified. Topics include Jordan elimination, the simplex method, the transportation problem, Chebyshev approximation, and convex programming. Though the jacket describes it as suitable for those "interested in advanced programming," the authors do not appear to assume any previous acquaintance with linear programming. T (16–17, if supplemented by exercises, since there are none in this book), S, T, L.

History

Bullettino di bibliografia e di storia delle scienze matematiche e fisiche, Vol. 1–20 (all published), Rome 1868–1887. With general index in volume 20. Reprint by Johnson Reprint Corporation. Cloth bound set $400, paper bound set $375; per volume paper bound $20. This famous serial, also known as "Boncompagni," is indispensable for the history of mathematics and ought to be in every mathematics research library. L.

The Encyclopedia of Philosophy. Edited by Paul Edward. Macmillan, New York, 1967. 8 volumes, app. 4300 pp. This attractive and readable encyclopedia testifies to the close ties between mathematics and philosophy and contains much biographical, historical and expository material of interest to mathematicians and suitable for supplementary reading by students. Among many articles, we mention Theory of Types (Y. Bar-Hillel), Number (S. F. Barker), David Hilbert (P. Bernays), Probability (M. Black), Combinatory Logic (H. Curry), Recursive Function Theory (M. Davis), G. Frege (M. Dummett), Set Theory (A. Fraenkel), Formal Systems and Their Models (L. Henkin), Continuity (S. Korner), Foundations of Mathematics (C. Parsons), History of Logic (A. N. Prior and others), Continuum Problem (R. M. Smullyan), Decision Theory (P. Suppes), Logical Paradoxes (J. van Heijenoort), Gödel's Theorem (ditto), Computing Machines (G. M. Weinberg). The bibliographies are good, but the Glossary of Logical Terms is unreliable. There is an index of 157 pages. S, P, L.

Britannica Book of the Year 1967. Encyclopaedia Britannica, Chicago, 1967. 832 pp. +a statistical supplement of 64 pages. Of interest to mathematicians are a two column article by Irving Kaplansky, which briefly mentions the main achievements of the year 1966, two paragraphs in the article on economics, which describe the triumph of mathematical methods in economic research and in Soviet planning, a description of the increased importance of mathematics in the article on geology, and two paragraphs in the article on philosophy relating to logic and mathematics. S, L.

The Basic Laws of Arithmetic. By Gottlob Frege. Translated and edited with an introduction by Montgomery Furth. University of California Press, Berkeley, 1967. lxiii+143 pp. (paper) $1.95. This is the first paperbound edition of a translation of *Grundgesetze der Arithmetik* (1893). The editor's introduction is a substantial 54 pages. S, L.

Mathematics Dictionary, Spanish-English/English-Spanish. By Mariano Garcia. Hobbs, Dorman, New York, 1965. vii+78 pp. $2.50. This brief dictionary is, as far as we know, the only English-Spanish mathematical dictionary now available. It appears to be up to date and should be useful to both English-speaking and Spanish-speaking mathematicians. P, L.

The Mathematical Papers of Sir William Rowan Hamilton. Vol. III, Algebra. Edited for the Royal Irish Academy by H. Halberstam and R. E. Ingram. Cambridge University Press, New York, 1966. xx+647 pp. $37.50. Vols. I (Optics) and II (Dynamics) appeared in 1931 and 1940. The editors promise a fourth "and final" volume of papers on analysis and geometry "in a few years." There is a facsimile of Hamilton's first notes on quaternions and a nine page introduction. P, L.

Fom Frege to Gödel, a Source Book in Mathematical Logic, 1879–1931. Edited by Jean van Hiejenoort. Harvard, Cambridge, Mass., 1967. xii+660 pp. $18.50. Forty-six papers, originally written in seven languages, are here translated into English and presented in chronological order beginning with Frege's epoch making *Begriffsschrift.* They were selected to depict the main strand of development. The last paper is by Herbrand on the consistency of arithmetic. This is one of a series of source books "of classical papers that have shaped the structure of the various sciences." The series is intended to cover all major sciences from ancient times to the middle of the present century, and several mathematical volumes are in preparation. This volume complements the collection edited by Copi and Gould (See below under Logic.) S, T, L.

The Six-Cornered Snowflake. By Johannes Kepler. Edited and translated by Colin Hardie, with essays by L. L. Whyte and B. F. J. Mason. Oxford, London, 1966. xiv+74 pp. $3.40. The English translation and modernized Latin are printed on facing pages. The essays deal respectively with the modern theory of snow crystals and with Kepler's effort in its historical context. S, P, L.

Mathematics and the Sciences of the Heavens and the Earth. Volume 3 of Science and Civilization in China. By Joseph Needham. Cambridge University Press, 1959. xlvii+878 pp. $30.00. Pages 1–168 deal with Chinese mathematics. The most thorough treatment of its subject, this work has forced the rewriting of ancient and medieval mathematical history. It ought to be in mathematics libraries as well as in reference sections of general libraries. P, L.

Festband zum 70. Geburtstag von Rolf Nevanlinna. Edited by H. P. Kunzi and A. Pluger. Springer-Verlag, Berlin, New York, 1966. 149 pp. 24 DM. Thirteen papers in honor of Nevanlinna's seventieth birthday plus a five-page biographical sketch and a bibliography of his published works. P, L.

The Mathematical Papers of Isaac Newton. Vol. I. 1664–1666. Edited by D. T. Whiteside with the assistance in publication of M. A. Hoskin. Cambridge University Press, 1967. xlvii+590 pp. $40. This magnificent volume is the first of eight in which all the known mathematical papers (many previously unpublished) will appear in an annotated and critical edition in which Latin materials will be printed with opposing English translations. This volume covers Newton's final year at Trinity College and the two following spent at home to escape the plague, during which he laid the basis of the calculus and the theory of light. There is a twenty-one page general introduction to the series and one of equal length for this volume, both written by the editor, who has already devoted a decade at Cambridge to researches related to Newton. P, L (!).

The Mathematical Works of Newton. Volume 1. Assembled with an introduction by Derek T. Whiteside. The Sources of Science, No. 3. Johnson Reprint Corporation, New York, 1964. xix+160 pp. $14.50. This fine volume contains facsimile reproductions of early English translations of three important mathematical works: *Analysis by equations of an infinite number of terms* (1745), *A treatise on the method of fluxions and infinite series* (1737), and *Quadrature of curves* (1710). This and a second planned volume complement *The Mathematical Papers* under the same editor. P, L(!).

Regiomontanus on Triangles. De triangulis omnimodis. By Johann Müller, otherwise known as Regiomontanus, translated by Barnabas Hughes, O.F.M., with an Introduction and Notes. University of Wisconsin Press, Madison, 1967. 298 pp. $10.00. In 1464, Regiomontanus "gathered together the trigonometric knowledge of his predecessors and enriched it with his own improvements." This fine edition of the first treatise on trigonometry gives the original in facsimile with translation on facing

pages. The introduction includes a ten page biography. Congratulations to Father Hughes and to the University of Wisconsin Publications in Medieval Science, edited by Marshall Clagett! S, P, L. Reviewed by D. J. Struik in *Science*, 28 July 1967.

Mathematical and Physical Papers. By George Gabriel Stokes. A reprint of the second edition of 1880–1905 which included annotations, biographical articles by Lord Kelvin and Lord Rayleigh, and portions of the original papers omitted from the first edition. With a new preface by C. Truesdell. No. 33 of The Sources of Science series. Johnson Reprint Corporation, New York, 1966. Five volumes, 360, 366, 421, 385, 402 pp. Cloth $75.00. L.

A Concise History of Mathematics. By Dirk J. Struik. Third edition. Dover, New York, 1967. x+195 pp. (paper) $2.00. The additional material on China, based on the work of Needham and others, makes this new edition of interest even to those who are completely familiar with its predecessors, which have been translated into more languages and been more widely read than any other contemporary history of mathematics. The bibliographies have been extended. T (as an introduction in a history course), S (in any mathematics course!), P, TT, L.

Logic and Foundation

The Undecidability of the Domino Problem. By Robert Berger. Memoirs of the American Mathematical Society, Number 66. American Mathematical Society, 1966. 72 pp. $1.90 (paper). A domino set is a finite number of infinite sets of congruent squares. Whether the infinite plane can be covered by squares chosen from an arbitrary domino set is proved undecidable. P, L.

Set Theory and the Continuum Hypothesis. By Paul J. Cohen. Benjamin, New York, 1966. 154 pp. $8.00. These notes on a course given at Harvard in 1965 are intended to give a self-contained exposition of the author's proof of the independence of the continuum hypothesis, for which he received a Fields Medal in 1966. Cohen addresses himself to the nonspecialist, avoids a formalistic style, and gives background material on logic, set theory, the consistency of the continuum hypothesis, formal systems, undecidable statements and recursive functions—all of which may be omitted by "the reader who has had an introductory course in logic." The author and publisher are to be congratulated for publishing these notes rather than waiting for the more polished version that doubtless will be forthcoming in due time. By so doing they afford the mathematical public a direct view of an exciting and significant sector of contemporary research in the foundations. S (17), P, L.

Contemporary Readings in Logical Theory. By Irving M. Copi and James A. Gould Macmillan, New York, 1967. 342 pp. $4.50 (paper). This is a book of readings for supplementary use in courses in symbolic logic. The essays are grouped in nine parts history of logic (Lewis, Langford, Kneale), the formal approach (Wang, Myhill, Nagel, Newman), meaning and reference (Frege, Russell, Strawson), theory of types (Russell, Fitch), logic and ontology (Quine, Carnap, Church, Goodman), logic and ordinary language (Ryle, Strawson, Quine, Geach), modal logic (Lewis, Quine, Fitch, Marcus), deontic logic (Wright, Anderson, O. K. Moore), and many valued logics (Rosser, Turquette). S, P, L.

Juristische Logik. By Ulrich Klug. Third enlarged and revised edition. Springer-Verlag, New York, 1966. xv+189 pp. Topics include the concept of juridical logic, pure logic and logic applied to the law, special arguments of legal logic, computers and the law, axiomatization of the law. Of interest to both logicians and jurists, this book is a candidate for translation. S, P.

theory and a one semester undergraduate course in general topology, the book introduces "as painlessly as possible" 2-dimensional manifolds, the fundamental group, and covering spaces, plus the group theory needed in these topics. Homology theory is intentionally not included. This is part of a series edited by Salomon Bochner and W. G. Lister, who in their foreword advocate more short, single-topic books to permit greater flexibility in college teaching—an idea that seems to be taking hold and deserves encouragement. T (16–17), P. L.

The Four-Color Problem. By Oystein Ore. Academic Press, New York, 1967. xv +259 pp. $12.00. This comprehensive study is certainly *the* book on its subject. It is an analysis of the entire literature, including important related studies in graph theory and map coloration problems. It combines history, exposition, analysis, and contributions—the latter via revision of many proofs. Pointing out that "one often sees in the history of mathematics, a fresh and comprehensive review of a subject has been the starting point for strong progress by the younger generation of mathematicians," the author expresses the hope that his work will have "some influence of this kind." It should be equally useful as a summary of achievements or a starting point for new departures. S, P, L.

Lecture Notes on Elementary Topology and Geometry. By I. M. Singer and John A. Thorpe. Scott, Foresman, Glenview, Ill., 1967. 220 pp., $6.25 paper. These notes are motivated by a desire to break up the compartmentalization of undergraduate education "at least in topology-geometry." "What the student has learned in algebra and advanced calculus is used to prove some fairly deep results relating geometry, topology, and group theory." The idea for such a course was conceived during the first author's "tour of duty for the Committee on the Undergraduate Program in Mathematics." Topics include the fundamental group, covering spaces, simplicial complexes, manifolds, homology theory, the De Rham theory, intrinsic Riemannian geometry of surfaces, and imbedded manifolds in R^3. T(16–17), S, T, L. The price of less than 3¢ a page compares very favorably with some books selling for more than three times this rate.

Connectivity in Graphs. By W. T. Tutte. University of Toronto Press, Toronto, 1966. ix+145 pp. $6.00. For those interested in research in the field. P.

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor Charles Hayes, University of California, Davis, represented the Association at the Dedication of Sonoma State College on May 27, 1967.

University of Hawaii: Miss Dorothy I. Koehler and Mr. J. K. M. Siu have been promoted to Assistant Professors; Assistant Professor Z. Z. Yeh has been promoted to Associate Professor; Assistant Professor W. J. Leahey has been promoted to Associ-

PERSONAL ITEMS

Professor Charles Hayes, University of California, Davis, represented the Association at the Dedication of Sonoma State College on May 27, 1967.

University of Hawaii: Miss Dorothy I. Koehler and Mr. J. K. M. Siu have been promoted to Assistant Professors; Assistant Professor Z. Z. Yeh has been promoted to Associate Professor; Assistant Professor W. J. Leahey has been promoted to Associ-

ate Professor and appointed Chairman of the Mathematics Department; Associate Professor E. H. Mookini has been promoted to Professor.

University of Illinois: Assistant Professors K. I. Appel, Hyman Gabai and P. M. Weichsel have been promoted to Associate Professors; Associate Professor R. W. Carroll has been promoted to Professor; Professor K. T. Chen, SUNY at Buffalo, and Dr. J. L. Selfridge, Pennsylvania State University, have been appointed Professors; Associate Professor H. S. Leonard, Jr., Carnegie Institute of Technology, has been appointed Visiting Associate Professor; Mr. H. E. Benzinger, Jr., Syracuse University, Mr. D. K. Friesen, Dartmouth College, and Mr. D. G. McRae, University of Washington, have been appointed Assistant Professors.

Montana State University: Dr. L. C. Barrett, Clarkson College of Technology, has been appointed Head of the Mathematics Department; Dr. B. L. McAllister, South Dakota School of Mines and Technology, has been appointed Associate Professor; Doctors N. H. Eggert, Colorado State College, Vinnie H. Miller, Brigham Young University, G. H. Ryder, Clarkson College of Technology, and K. J. Tiahrt, Oklahoma State University, have been appointed Assistant Professors.

Wesleyan University: Dr. J. F. Berglund, Tulane University, has been appointed Assistant Professor; Mr. E. M. Coven, Yale University, has been appointed Assistant Professor; Professor W. W. Comfort, University of Massachusetts, has been appointed Professor.

Dr. D. C. Bossard, Dartmouth College, has accepted a position with Daniel H. Wagner Associates.

Professor H. L. Dorwart, Trinity College, has been appointed Dean of the College.

Dr. E. J. Eckert has been appointed Chairman of the Department of Mathematics at California State College at Los Angeles.

Dr. J. B. Goebel, Pacific Northwest Laboratory, has been appointed Professor and Head of the Department of Mathematics at the Montana School of Mines.

Assistant Professor Dagmar Henney, The George Washington University, has been promoted to Associate Professor.

Mr. R. R. Holbert, Bob Jones University, has accepted a position with the IBM Corporation in the Systems Development Division.

Associate Professor Taqdir Husain, McMaster University, has been promoted to Professor and appointed Acting Chairman of the Mathematics Department.

Professor J. S. Mac Nerney, University of North Carolina at Chapel Hill, has been appointed Professor at the University of Houston.

Professor A. O. Boatman, Carthage College, died on January 19, 1967. He was a member of the Association for twenty-eight years.

Professor Emeritus P. P. Boyd, University of Kentucky, died on December 19, 1966. He was a Charter Member of the Association.

Professor Emeritus R. D. Carmichael, University of Illinois, died on May 2, 1967 at the age of 88. He was for many years dean of the graduate school of the University of Illinois. He was a Charter Member of the Association. He served as President in 1923, Vice President in 1921–22, Member of the Committee on the Official Journal 1916–18, and was an elected member of the Board of Governors in 1920, 1924–29, and 1939–41.

Professor Emeritus Mabel M. Heren, Knox College, died on February 19, 1967. She was a member of the Association for forty-seven years.

Instructor Emeritus W. W. Johnson, Cleveland State University, died on November 1, 1966. He was a Charter Member of the Association.

Professor Emeritus G. W. Spenceley, Miami University, died on March 6, 1967. He was a member of the Association for forty-six years.

CONFERENCE ON COMMUNICATION PROBLEMS IN THE MATHEMATICAL SCIENCES

The American Mathematical Society will hold a Conference on Communication Problems in the Mathematical Sciences on December 5, 6, and 7, 1967, in Providence, Rhode Island. The scientific sessions will take place at the Sheraton-Biltmore Hotel, and the program will include the official opening of the new AMS headquarters office building in Providence.

The purpose of the Conference is to consider improved means of retrieval, categorization, distribution, and collection of mathematical material. The Conference will encourage cooperation among organizations in the mathematical community in the development of new guidelines for an integrated, balanced information system. The participation of distinguished scientists in other disciplines and from other countries will insure an overall perspective of communication problems.

All interested mathematicians and scientists are invited to attend the Conference. Information concerning accommodations and a complete Conference program may be obtained from the American Mathematical Society, P. O. Box 6248, Providence, Rhode Island 02904.

THE UNIVERSITY OF TEXAS—SIXTH ANNUAL SYMPOSIUM ON BIOMATHEMATICS AND COMPUTER SCIENCE IN THE LIFE SCIENCES

The University of Texas Graduate School of Biomedical Sciences at Houston, Division of Continuing Education, is pleased to announce the Sixth Annual Symposium on Biomathematics and Computer Science in the Life Sciences, which will be held at the Shamrock Hilton Hotel in Houston, Texas, on March 14–16, 1968. The theme of the symposium is MAN, MACHINES, MATHEMATICS, AND MEDICINE. The topics for the sessions of the symposium are: 'Quantitative and Theoretical Biology,' 'Mathematical and Applied Statistical Problems in Biomedical Research,' 'Experimental Design in the Biomedical Sciences', 'Bioengineering,' 'Information Management: Storage and Retrieval,' 'Computer Applications in the Biomedical Sciences,' and 'The Man-Machine Interface.'

Papers of an interdisciplinary nature will be particularly welcomed by the Program Committee, as will appropriate papers on education. Those interested in submitting abstracts should contact the Office of the Dean, The University of Texas Graduate School of Biomedical Sciences at Houston, Division of Continuing Education, P. O. Box 20367, Houston, Texas 77025. *Abstracts will not be reviewed for inclusion in the program after December 15, 1967.*

FELLOWSHIP AND RESEARCH OPPORTUNITIES IN MATHEMATICS

The Division of Mathematical Sciences of the National Research Council calls attention to a number of fellowships and other support for research in the mathematical sciences at both the predoctoral and postdoctoral levels to be awarded during the year 1967–68. Copies of the complete announcement are available from: Division of Mathematical Sciences, National Research Council, 2101 Constitution Avenue, N. W., Washington, D. C. 20418.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

THE FORTY-EIGHTH SUMMER MEETING OF THE ASSOCIATION

The Forty-eighth Summer Meeting of the Mathematical Association of America was held at the University of Toronto, Toronto, Ontario, Canada, from Monday, August 28, to Wednesday, August 30, 1967, in conjunction with meetings of the American Mathematical Society, the Canadian Mathematical Congress, the Society for Industrial and Applied Mathematics, the Econometric Society, the Pi Mu Epsilon Fraternity, and Mu Alpha Theta. The lectures by Professors Coxeter and Lehner on Monday and by Professor Samuel on Tuesday were joint sessions with the Canadian Mathematical Congress. The last lecture on Wednesday afternoon was a joint session with the Econometric Society. There were registered 2250 persons, including 850 members of the Association.

Sessions of the Association were held on Monday morning and afternoon, on Tuesday morning, and on Wednesday afternoon. All sessions were held in Convocation Hall of the University of Toronto. Presiding officers at the three Earle Raymond Hedrick Lectures were President E. E. Moise, First Vice-President G. S. Young, and Second Vice-President R. J. Walker; at the presidential address to the Canadian Mathematical Congress by Professor Coxeter, Professor A. W. Tucker; at the lecture by Professor Lehner, Professor Maurice L'Abbe; at the panel discussion on Monday afternoon, Professor V. L. Klee; at the lecture by Professor Samuel on Tuesday morning, Professor G. de B. Robinson; at the panel discussion on Wednesday afternoon, Professor P. D. Lax; and at the joint session with the Econometric Society, Professor Daniel McFadden. The sixteenth series of Earle Raymond Hedrick Lectures was delivered by Professor Gian-Carlo Rota of the Massachusetts Institute of Technology and the Rockefeller University. The Program Committee consisted of G. de B. Robinson, Chairman; T. E. Hull, P. D. Lax, A. H. Stone, and W. T. Tutte.

FIRST SESSION OF THE ASSOCIATION

Welcome on behalf of the University by Professor G. de B. Robinson, Vice-President, University of Toronto, and response by Professor E. E. Moise, President of the Association.

The Earle Raymond Hedrick Lectures: *Combinatorial Analysis as a Theory*, Lecture I, by Professor Gian-Carlo Rota, Massachusetts Institute of Technology and the Rockefeller University.

The Problem of Apollonius, Presidential Address to the Canadian Mathematical Congress, by Professor H. S. M. Coxeter, University of Toronto.

In the real inversive plane, three nonintersecting circles may be either Apollonian (so that exactly eight circles touch them all) or "nested" (so that no circle touches them all). Any two nonintersecting circles have a unique "mid-circle" which inverts each of them into the other. The three mid-circles of an Apollonian triad are coaxal. Any two nonintersecting circles have an "inversive distance," which is the logarithm of the ratio of the radii of two concentric circles into which the given circles can be inverted. Let a, b, c be the inversive distances between pairs of circles in an Apollonian triad. Among the eight circles that touch the three, two are nonintersecting if and only if each of the three numbers $\cosh \frac{1}{2}a$, $\cosh \frac{1}{2}b$, $\cosh \frac{1}{2}c$ is less than the sum of the other two

The Picard Theorems, by Professor Joseph Lehner, University of Maryland.

The theorems are: (1) a nonconstant entire function assumes every complex value with one possible exception; (2) in every neighborhood of an isolated essential singularity a holomorphic function has the same property. In graduate courses (1) is commonly proved by the elliptic modular function, but (2) is then established by the so-called "elementary" (Landau-Schottky) approach.

Here it is shown that once the modular function has been developed, (2) can be proved without much additional work. The modular function can also be used to prove Landau's and Schottky's theorems and to derive the exact values for the constants therein.

SECOND SESSION OF THE ASSOCIATION

Hedrick Lecture II, by Professor Rota.

Panel Discussion on Geometry in the University, by Professor Walter Prenowitz, Brooklyn College, Professor Seymour Schuster, University of Minnesota, and Professor F. A. Sherk, University of Toronto, with Professor V. L. Klee, University of Washington, as moderator.

Professor Schuster described the College Geometry Project at the University of Minnesota, including its aims and accomplishments. While this project is primarily concerned with the education of prospective secondary teachers, the work of the project has considerable bearing on, and non-trivial implications for, the geometry courses for mathematics majors. These implications were elucidated.

Professor Sherk outlined and discussed the undergraduate geometry courses given at the University of Toronto.

Professor Prenowitz's theme was that n-dimensional (linear) geometry can be successfully studied by employing intrinsic methods without assuming the existence of coordinates or vectorial representations. The principal illustrations given were the join theoretic methods that appear in the speaker's Slaught Memorial Paper (this MONTHLY, Vol. 68 No. 1, January 1961). Specific topics considered were the generation of convex sets and linear spaces, properties of half-spaces, separation theorems and the theory of linear independence and dimension. Much of the treatment described is not merely coordinate-free but dimension-free as well.

Professor Klee then listed and discussed six desiderata for undergraduate geometry courses and explained how the geometry of convex bodies can be presented so as to include all six desirable features. An article based on this presentation will appear in the MONTHLY.

General Discussion by the Panel and the Audience

THIRD SESSION OF THE ASSOCIATION

Hedrick Lecture III, by Professor Rota.

Business Meeting of the Association; presentation of L. R. Ford Awards.

Unique Factorization, by Professor Pierre Samuel, University of Paris.

Arithmetic and geometric characterizations of unique factorization in commutative rings were discussed, in particular, the methods used for proving that a ring is factorial; relations of factorial rings with more general (e.g. Krull) rings and more special classes of rings (e.g. principal or Euclidean rings); the behaviour of factorial rings under various ring-theoretic operations (rings of quotients, polynomials, power-series, rings of invariants). Some deeper properties, related with Grothendieck's theory of schemes, were stated.

FOURTH SESSION OF THE ASSOCIATION

Panel Discussion on What to Do Till the Computer Scientist Comes, by Professor G. E. Forsythe, Stanford University, Professor T. E. Hull, University of Toronto, and Professor Marvin Minsky, Massachusetts Institute of Technology, with Professor P. D. Lax, New York University, as moderator.

Professor Forsythe defined computer science and discussed its many applications, its relation to mathematics, and the activities of the approximately 35 existing computer science departments. He gave the following answers to the question of the title: (1) get a little bit acquainted with computing by programming, and by reading some books from a recommended list; (2) study how computing intersects mathematics and keep this in mind as you teach; (3) help the computer scientist feel welcome when he comes but expect a big blast of computing activity; (4) (optional) tackle a mathematical research problem that would help computer science and your publication list (sample problem areas were given).

Professor Hull felt that much of what is now being taught about computing to freshmen and sophomores will soon be available in most high schools. About one in ten Ontario high schools now offers a two-year option in Computer Science, and the number is increasing rapidly. This development can have a very beneficial effect on existing courses in mathematics, by reinforcing the concepts of sets, functions, the nature of proof, etc., and by introducing the concept of an algorithm in a fundamental and meaningful way.

Professor Minsky suggested that one should first ask how to tell when Computer Science has arrived. This will be true when the graduate students know more than the undergraduates. The most serious problems center around the lack of realistic mathematical models for Computation, and young mathematicians should be encouraged to work on: theory of reciprocity between memory-size and number of computation-steps; reciprocity between local and global methods of pattern-recognition (to shed more light on the relation between serial vs. parallel algorithms); finding methods for establishing lower bounds for what is necessary for particular algorithms, as in numerical, sorting, and algebraic-manipulation problems. These are much more important than most workers realize, and good results that seem special and *ad hoc* at first may lead to large new theories.

The worldly demands of Computation Science will bring heavy pressure on Mathematics Departments to become more "Applied." The priceless integrity of Pure Mathematics must be protected by expansion rather than dilution, for Computation is, he believes, to become the largest and most powerful of our technological and intellectual disciplines.

JOINT SESSION WITH THE ECONOMETRIC SOCIETY

Numerical Representation of Preference Orderings, with an Application to Infinite Consumption Sequences, by Professor T. C. Koopmans, Cowles Foundation for Research in Economics, Yale University.

The speaker started with a set of axioms about a preference ordering on a space of infinite sequences of future consumption vectors. He constructed a numerical representation of such a preference ordering by a discounted sum of future utilities. A slight weakening of one axiom permits a wider class of representations in which the discount rate for constant consumption sequences varies with the utility of the consumption vector in question.

SPECIAL SESSIONS OF THE ASSOCIATION

Film showings were held in Concert Hall of the Edward Johnson Building as follows:

Sunday, 7:00–7:47 P.M. MEASURES AND SET THEORY: A Lecture by Stanislaw Ulam (A CEM Individual Lectures film in b & w).

8:00–9:03 P.M. NIM AND OTHER ORIENTED GRAPH GAMES: A Lecture by Andrew M. Gleason (A CEM Individual Lectures film in b & w).

Films of the College Geometry Project of the University of Minnesota (in color).

Monday, 7:00–7:12 P.M. ORTHOGONAL PROJECTION by Daniel Pedoe; 7:13–7:23 P.M. CENTRAL SIMILARITIES by Daniel Pedoe; 7:24–7:36 P.M. DIHEDRAL KALEIDOSCOPES by H. S. M. Coxeter; 7:37–7:54 P.M. GEOMETRIC VECTORS by Wm. O. J. Moser and S. Schuster; 8:05–8:18 P.M. INVERSION by Daniel Pedoe; 8:19–8:35 P.M. CURVES OF CONSTANT WIDTH by J. D. E. Konhauser; 8:36–8:49 P.M. CENTRAL PERSPECTIVITIES by S. Schuster.

CEM Animated Calculus Films (in color).

9:00–9:15 P.M. THE DEFINITE INTEGRAL by Charles E. Rickart; 9:16–9:24 P.M. VOLUME BY SHELLS by George F. Leger; 9:25–9:39 P.M. FUNDAMENTAL THEOREM OF THE CALCULUS by Morris Schreiber; 9:40–9:50 P.M. THE THEOREM OF THE MEAN by Felix P. Welch;

Tuesday, 7:00–8:03 P.M. JOHN VON NEUMANN (A CEM Individual Lectures film in b & w).

CEM Animated Level I Films (in color).

8:15–8:29 P.M. WHAT IS A SET? 8:29–8:39 P.M. ONE-TO-ONE CORRESPONDENCE; 8:39—8:48 P.M. COUNTING, 8:48–8:56 P.M. UNION AND INTERSECTION; 8:56–9:04 P.M.

ADDITION AND SUBTRACTION.

9:20–10:20 P.M. WHO KILLED DETERMINANTS: A Lecture by Kenneth O. May (A CEM Individual Lectures film in b & w).

10:22–10:30 P.M. MULTIPLICATION AND DIVISION. (A CEM Animated Level I film in color).

MEETING OF THE BOARD OF GOVERNORS

The Board of Governors of the Association met on Sunday at 10:00 A.M. in Room 134 of the McLennan Laboratories at the University of Toronto, with thirty-eight members present. Among the items of business transacted were the following:

The Board elected Professor A. B. Willcox of Amherst College as Executive Director of the Association for a term beginning on or about August 1, 1968.

The Board elected Professor C. J. A. Halberg, Jr. of the University of California, Riverside, as Governor from the Southern California Section to fill the unexpired part of the term ending June 30, 1968, of Professor R. C. James, who has moved from the Southern California Section.

The Board voted to invite Professor Hyman Bass of Columbia University to deliver the seventeenth series of Earle Raymond Hedrick Lectures at the 1968 Summer Meeting.

In accordance with a petition submitted by 34 members of the Association residing in Florida and upon the recommendation of the Committee on Sections, the Board voted to authorize the establishment of a Florida Section as of September 1, 1967, with the exact territory to be covered by the Section to be determined at a later date. The Board then elected Professor D. B. Goodner of Florida State University as the first Governor from the Florida Section for a term ending June 30, 1968, with the possibility that the Section can re-elect him for a full three-year term if it so desires.

Upon the recommendation of the Finance Committee, the Board set the annual dues for academic members at $50, beginning with 1968.

The Executive Director reported the membership of the Association as 17,596 individual members, 3 corporate members, and 245 academic members.

Upon the recommendation of the Executive and Finance Committees, the Board approved a proposal, originally made in a slightly different form by Professor Grosswald, for additional awards to be made to high ranking participants in the Putnam Competition as follows:

(a) The Board encourages the Sections to offer free one-year memberships in the MAA to participants in the Putnam Mathematical Competition who have achieved high scores, to be financed, wherever possible, from funds available to the Sections.

(b) The national office shall offer (in addition to the present prizes) five free one-year memberships in the MAA to the five students who scored individually highest in the Putnam Mathematical Competition, regardless of the success of their respective teams.

(c) Sections whose resources might be severely strained by offering two free one-year memberships in the Association might wish to apply for funds from the annual appropriation of $500 available to the Committee on Sections for worthwhile projects of the Sections.

The Board passed a resolution of thanks to the Du Pont Company for its contribution of $5000 toward printing and distributing the brochure YOU'LL NEED MATH.

The Board of Governors authorized the Secretary to send a letter of appreciation and thanks to the National Science Foundation recognizing their valuable support in mathematical education and research; copies of this letter are to be sent to the appropriate congressional committees and to officers of the National Science Foundation.

BUSINESS MEETING OF THE ASSOCIATION

A business meeting of the Association was held on Tuesday morning with President Moise presiding.

The third set of L. R. Ford Awards were presented by President Moise to authors of expository articles published in the MONTHLY and the MATHEMATICS MAGAZINE in 1966. The Awards, in the amount of $100 each, were presented for five articles (for

further details on these Awards, see the August–September issue of this MONTHLY, page 908).

The Secretary then reported on some of the actions taken by the Board on Sunday. He announced that, in accordance with the recommendation of the Committee on the Future Administrative Structure of the Association, the Association has decided to move its central office to Washington, D.C. The reasons for the decision to move to Washington are best expressed in a resolution adopted by the Executive and Finance Committees at their meeting in Washington, D.C. on July 9. He then read the resolution which appears on page 1176 of this issue of the MONTHLY.

This resolution has been sent to the presidents and secretaries of all the major organizations in the mathematical sciences. Expressions of interest in cooperation have already been received from many of these organizations.

The Secretary reported the receipt of a grant of $716,495 from the National Science Foundation for the support of the Committee on the Undergraduate Program in Mathematics. He stressed the Association's gratitude to the Foundation for this grant and the confidence which it expresses in the Association's past work in improving undergraduate instruction in mathematics.

The Secretary also reported the receipt of $5000 from an anonymous donor to support certain activities of the Committee on Educational Media which were not provided for in the grant from the National Science Foundation.

The Secretary announced that copies of the second edition of the GUIDEBOOK TO DEPARTMENTS IN THE MATHEMATICAL SCIENCES IN THE UNITED STATES AND CANADA are available from the Buffalo Office of the Association for 50 cents per copy. This book provides in summary form information about the location, size, staff, library facilities, course offerings, and special features of departments in the mathematical sciences in 1200 four-year colleges and universities in the United States and Canada.

He also announced that the seventh edition of PROFESSIONAL OPPORTUNITIES IN MATHEMATICS has just been published and is available from the Buffalo office of the Association for 25 cents per copy. To be published early in 1968 are: MAA STUDIES No. 5: Studies in Modern Topology, edited by Peter Hilton and CARUS MONOGRAPH No. 15, Non-Commutative Rings, by I. N. Herstein.

He announced the appointment of a Committee on Assistance to Negro Colleges, which is to consider various possibilities in which the Association might be able to assist Negro colleges. This Committee consists of George Springer, Chairman; R. D. Anderson, Murray Braden, L. L. Clarkson, C. O. Oakley, B. E. Rhoades, M. B. Smith, Jr., and F. M. Stewart.

The Secretary expressed the gratitude of the Association to the University of Toronto for having made their excellent facilities available for this meeting and ascribed the success of this meeting to the careful and energetic planning of the local Committee on Arrangements under the chairmanship of Professor Chandler Davis. He expressed special appreciation also to Professor F. A. Sherk for his imaginative handling of the publicity for this meeting.

He announced the following schedule of future meetings: San Francisco, California, January 25–27, 1968; University of Wisconsin, Madison, August 26–28, 1968; New Orleans, Louisiana, January, 1969; University of Oregon, August 25–27, 1969; Miami, Florida, January, 1970.

A motion to amend Article V of the By-Laws of the Association, as it appears on pages 624–25 of this MONTHLY, was then approved.

MEETING OF SECTION OFFICERS

The meeting of representatives of the Sections was held on Monday evening in Room 102 of the McLennan Laboratories. Professor L. E. Mehlenbacher, Chairman of the

Committee on Sections, presided. Fifty-three persons were present, representing twenty-six of the twenty-seven Sections of the Association.

President Moise reported on the visits he has made to the Sections. Of all the activities connected with the presidency, he considered his visits to the sections the most pleasant. While we meet nationally—or internationally—twice a year, the work of the Association is carried out in the Sections; for most of the members most of the year, the Sections are the Association. The work of CUPM, for example, could not be carried out successfully without the assistance of the Sections. He wished luck and success to the Sections in their future work.

Sister Mary Paul Buser, Chairman of the Kansas Section, reported on the special awards for the Putnam Mathematical Competition made by the Kansas Section. In addition to a one-year membership in the MAA, each of the top five students in the State receives a monetary award, which is made at the luncheon of the spring meeting of the Section.

Professor C. T. Long, Chairman of the Pacific Northwest Section, gave a report on efforts on the Pacific Northwest Section to reach junior college personnel. Discussion with junior college teachers revealed that they felt a need for special programs at Section meetings for teachers at this level as well as possible representation on the Executive Committee of the Section. Such programs, stressing the teaching of mathematics at the appropriate level, were arranged for the 1966 and 1967 meetings. These sessions were well attended, and continued efforts along these lines are expected to receive support. At the 1967 Section meeting, the By-Laws of the Section were amended to create the position of Second Vice-Chairman, who will represent the two-year college personnel on the Executive Committee, arrange the program for the two-year college sessions at the annual Section meetings, and preside at these sessions. Professor Long noted that the Section has an MAA representative at almost all of the two-year colleges, and that the Section was making an effort to attract members from these colleges.

Professor Dale Maness presented the report of the Texas Section Committee on "A General Curriculum in Mathematics for Colleges" (GCMC). The report concludes that "the evaluation committee feels that GCMC is a valuable contribution from CUPM even though its outline may not be specifically followed in many schools. It points out areas of the curriculum that will be of increasing importance . . . "

In answer to a question as to what disposition will be made of these reports by Sections on the GCMC report, Professor Alder reported that CUPM is planning to publish a representative compilation or synthesis of such reports when additional reports have been received from the Sections who have not as yet sent in their evaluations.

Professor D. T. Finkbeiner reported that the Ohio Section plans a special meeting this fall on collegiate mathematics and that they have had excellent support from CUPM and the officers of the Association in providing good speakers; this program has generated a considerable amount of enthusiasm in the Section.

Dr. Richard Balomenos reported on trends in the National Science Foundation, specifically, (1) the decision to discontinue the Visiting Scientist Program for Secondary Schools, (2) the construction of mathematical problems for use with secondary students; and (3) the new Office of Computing Activities.

As regards (1), NSF was confronted with a relatively level budget for support of science and mathematics in the pre-college area. Faced with the problem of providing for the continuing support of programs designed to meet longstanding needs in science and mathematics education, the Foundation has recently failed to meet its responsibility for providing support for new ideas. As a result, a program entitled "Special Projects in Science Education" was established and additional support was given to the Cooperative College-School Science Program for teacher training activities in the context of the needs of school systems. To provide for part of the increased support of these programs, it was necessary to discontinue the Visiting Scientist Program. It is hoped that as a re-

sult of the encouragement from NSF such visits to the secondary schools can continue with support from local sources.

In reference to (2), NSF has received numerous requests for support of projects to construct sets of mathematical problems for use by groups involved in talent search or mathematical contest activities. NSF has supported some of these projects. However, funds and talent are not available to provide for all the local requests. Hence, the question by NSF, "Is there need for a national or regional project to construct problem sets and assist local groups?"

Concerning (3), NSF has established an Office of Computing Activities under Dr. Milton Rose. One of the major aims of the office is to develop the potential of computers in the educational process at all levels. The comments and views from individual mathematicians or groups, such as the MAA, as well as specific proposals, will aid the office in establishing priorities for its activities.

President Moise, in commenting on the Visiting Scientist Program for Secondary Schools, felt that one of its main values was the impact made on students' attitudes toward mathematics when they realize that there are such people as mathematicians. One of the problems is to present mathematics as a live field. A way of demonstrating this is to present an example of one of the human beings who is an active worker in this field. He felt that the program is so important that he would like to see it continued on a voluntary basis. The impact a mathematician makes when spending an afternoon visiting a school will be well worth the effort. Dr. Balomenos also emphasized that discontinuance of NSF support should not mean the end of the program. He reported that in some areas the program is being supported by industry and others.

In the absence of Professor H. M. MacNeille, Director of the Calculus Film Project, a letter was read from him announcing that the films produced by the Calculus Film Project are now available from Modern Learning Aids.

Professor C. T. Salkind, Chairman of the Committee on High School Contests, reported on some changes in the Contest. He requested that the Section officers be familiar with, and make known through appropriate means, the following changes in the Annual High School Mathematics Contest for 1968:

(a) The number of questions is being reduced from forty to thirty-five with the maximum score remaining at 150.

(b) Problem subdivision into four parts is replacing the present three: Part I, consisting of ten "very easy problems," 3 credits each, Part II, with ten "easy" problems, 4 credits each, Part III, with ten "medium" problems, 5 credits each, and Part IV, with five "hard" problems, 6 credits each.

This revision (or one very similar to it) will be tried for a period of two years. If it receives general acceptance, and, nevertheless, maintains discriminatory power on various levels, it will be retained.

He also announced certain revisions in the composition of the ten regions in which the United States and Canada have been divided for the purposes of the Contest. He announced that the 1968 Contest would be held on Tuesday, March 12, 1968, and not on a Thursday as has been previously the case.

Professor R. E. Gaskell, Chairman of the Committee on Visiting Lecturers, discussed the history of this program from its initiation in 1954. He remarked that the number of day-visits is receding from a high in 1964–65, and the Committee seeks to extend the program to schools which have not previously been visited. The Committee proposes to contact Section Chairmen, asking for the names of schools in this category within the various Sections.

Professor R. D. Boswell, Jr., a member of the Committee, reported on the efforts made by the Committee to find out which lectures have been successful. They are usually asked to continue. This year, there will be 65 lecturers, of which approximately 25 will be new lecturers in the region in which they will make their visits.

Professor J. H. McKay, Director of the Putnam Mathematical Competition, re-

There was a party with dancing held at Casa Loma Castle on Tuesday at 9:00 P.M. SIAM conducted a beer party on Wednesday at 9:30 P.M. in Hart House. The University offered the participants a free concert on Thursday at 8:30 P.M. in Concert Hall. The artists were Lorand Fenyves, violinist, and Bela Siki, pianist. All-day bus tours to Niagara left on Wednesday and Thursday from Sidney Smith Hall at 9:40 A.M. on both days and returned at approximately 7:45 P.M. In addition, there were a number of local tours to points of interest in the Toronto area.

HENRY L. ALDER, *Secretary*

ACADEMIC MEMBERS ELECTED INTO THE ASSOCIATION

In accordance with the amendment adopted at the business meeting of the Association at Stillwater on August 30, 1961, the Board of Governors at its meeting in Toronto, Canada, on August 27, 1967, elected to membership the twelfth set of applicants for academic membership (for election of the other eleven sets, see the April and November issues for 1962–67). Approval for election was given to the following 9 applicants for academic membership:

Brock University, St. Catharines, Ontario, Canada
College of Artesia, Artesia, New Mexico
College of St. Thomas, St. Paul, Minnesota
Holy Trinity High School, Hicksville, New York
Inter American University, Puerto Rico
Miami Dade Jr. College, Miami, Florida
Mt. Hood Community College, Gresham, Oregon
Northern Virginia Community College, Bailey's Crossroads, Virginia
Pacific Lutheran University, Tacoma, Washington

In addition, the Board elected the American Mathematical Society as a corporate member.

HENRY L. ALDER, *Secretary*

MOVE OF MAA CENTRAL OFFICE TO WASHINGTON

The following resolution was approved by the Executive and Finance Committees of the Association on July 9, 1967, in Washington, D.C.:

"The Mathematical Association of America has decided to move its headquarters office to Washington, D.C., late in 1968. The decision was made at a meeting of the Executive and Finance Committees of the Association which was held in Washington on July 8, 1967.

The Mathematical Association of America takes this opportunity to invite other organizations in the mathematical sciences to join it in locating their headquarters in Washington, so that we all can realize, to the fullest extent, the advantages of a common location and the special advantages of Washington.

We believe that the work of the learned societies, in the mathematical sciences and in general, will become easier and more effective if informed day-to-day communication among them is made convenient. For this reason, in the long run, the learned societies should have their headquarters in some one city. And the city on which the learned societies have tended to agree is Washington because all these societies need to communicate not only with one another but also with the federal government.

In attempting to facilitate communication within the scientific community, the Mathematical Association of America is concerned primarily with the problems of scientific and educational policy. We hope, however, that if other organizations in the mathematical sciences also estab-

lish headquarters in Washington, then cooperative arrangements can be made for more economical handling of such operations as the editing of journals, publication of books, maintenance of membership lists, collection of dues, and so on."

HENRY L. ALDER, *Secretary*

RETIRED MATHEMATICIANS

The next issue of the List of Retired Mathematicians Available for Employment will be published in January 1968 by the Mathematical Sciences Employment Register. Besides being distributed to academic and industrial employers, who request the list from the Register office, copies will be available when the Register is open at the annual meeting in San Francisco, California, January 24–26, 1968. Retired mathematicians who are interested in being included in the list may either request a form from the Register office or send the following information: name, date of birth, highest degree earned and where it was obtained, most recent employment, present address, date available, references, preference for academic or industrial employment, and geographic location preferred. The deadline for receipt of either the completed form or the above information is January 1, 1968.

SUMMER EMPLOYMENT OPPORTUNITIES

The List of Opportunities for Summer Employment for Mathematicians and College Mathematics Students is being compiled and will be issued in January 1968. The list will be available free of charge at the annual meeting in San Francisco, California, in January and upon request from the Register office. Institutions and industrial concerns that have summer openings and would welcome applications from mathematicians and students of mathematics may request forms for listing from the Register office. The deadline for receipt of the completed forms is January 1, 1968.

THE EMPLOYMENT REGISTER

During the annual meeting in San Francisco, California, the Mathematical Sciences Employment Register will be open for the scheduling of interviews between applicants and employers. The Employment Register which is sponsored by the American Mathematical Society, the Mathematical Association of America, and the Society for Industrial and Applied Mathematics, will be located in the Imperial Ballroom of the San Francisco Hilton Hotel, and will be open from Wednesday, January 24, through Friday, January 26, from 9:00 A.M. to 5:00 P.M. on each of the three days. Registration for the Employment Register is *separate and apart* from meeting registration, and it is, therefore, most important that both applicants and employers sign in at the Employment Register Desk as early as they can on Wednesday morning. A separate visual index will be maintained for Employment Register use only. Appointments may be requested only with applicants and employers who have actually signed in at the Register.

There is no charge for registration except when the late registration fee of $5.00 is applicable. Provision will be made for anonymity of applicants upon payment of $5.00 to defray the cost involved in handling such a listing.

Applicants and employers who wish to be listed should write to the Mathematical Sciences Employment Register, Post Office Box 6248, Providence, Rhode Island 02904, for applicant qualification forms or position description forms. These forms must be completed and returned to the Employment Register not later than December 15, 1967, in order to be included in the January lists. Those forms which arrive too late to be included in the printed lists are taken to the meeting where they may be seen by applicants and/or employers who are interested in them. The printed lists will be mailed to sub-

scribers during the first week in January. Lists can be ordered from the Employment Register office in Providence. They will also be available at the meeting.

A subscription to the lists, which includes three issues (January, May, and August) of both the applicants list and the positions list is available for $25.00 a year. The individual issues of both lists may be purchased in January, May, and August for $12.50. A subscription to the applicants list alone or single copies of that list are not available. Copies of the positions list only may be purchased for $3.00. Checks should be made payable to the American Mathematical Society and sent to the address given above.

MARCH MEETING OF THE LOUISIANA-MISSISSIPPI SECTION

The forty-fourth annual meeting of the Louisiana-Mississippi Section of the MAA was held in the Jung Hotel, New Orleans, Louisiana, on March 3, 1967, in conjunction with a place of site meeting of the NCTM. There were 144 persons registered at the MAA sectional meeting, including 112 members of the Association.

The following officers were elected: N. A. Childress, University of Mississippi, Chairman; Patrick Ford, McNeese State College, Louisiana, Vice Chairman; Z. T. Gallion, Mississippi State College for Women, Mississippi, Vice Chairman; L. Virginia Carlton, Centenary College, Secretary-Treasurer.

The following papers were presented:

1. *Partially ordered Abelian groups*, by Robert Pendleton, Louisiana State University.

2. *Uniqueness theorems for a class of second-order differential equations*, by J. B. Garner, Louisiana Polytechnic Institute.

THEOREM 1. Let $f(x, y, z) \in C$ in $[a, b]XR^2$ and let $\beta_1, \beta_2 \in R$ and $a \leqq \alpha_1 \leqq \alpha_2 \leqq b$. If $f(x, y, z)$ is nonincreasing in y and nondecreasing in z for each fixed $x \in [a, \alpha_1]$, nondecreasing in y and z for each fixed $x \in [\alpha_1, \alpha_2]$, and nonincreasing in y and z for each fixed $x \in [\alpha_2, b]$, then there exists at most one solution of (1) $y'' = f(x, y, y')$ satisfying either (2) $y(\alpha_1) = \beta_1$, $y'(\alpha_2) = \beta_2$, or (3) $y(\alpha_1) = \beta_1$, $y(\alpha_2) = \beta_2$, $\alpha_1 \neq \alpha_2$.

THEOREM 2: Suppose the conditions of Theorem 1 hold except that for each fixed $x \in [\alpha_1, \alpha_2]$, $f(x, y, z)$ is nondecreasing in y and nonincreasing in z. Then there exists at most one solution of (1), (4) $y'(\alpha_1) = \beta_1$, $y(\alpha_2) = \beta_2$.

3. *Concerning the maximal convex subsets of a non-convex set of functions*, by C. R. Smith, Northeast Louisiana State College.

The author has shown that in any linear space the convex kernel of a nonconvex set is the intersection of the maximal convex subsets of the nonconvex set (to appear, this MONTHLY). In the space of real functions defined on the unit interval I, the class of functions defined by $D = \{f \mid f(I) \subset I, f(0) = 0, f$ discontinuous at $x_i \in I, 0 < i < N\}$, is a nonconvex set and has as its convex kernel the set, $ckD = \{f \in D \mid f$ is discontinuous at $x = 0\}$ (this MONTHLY, 73, 1966, 927). Interesting situations which arise when one attempts to find some maximal convex subsets of D and a possible relationship between this example and the unsolved problems of the dimension of convex kernels were discussed.

4. *Concerning absolute continuity*, by W. L. Bynum, Louisiana State University.

5. *A combinatorial problem from a design viewpoint*, by Lonnie T. Bennett, Northeast Louisiana State College.

A method of solving the combinatorial problem of generating Partially Balanced Incomplete Block Designs was given. The construction method replaces each treatment of a given Balanced or Partially Balanced Incomplete Block Design with an entire Balanced or Partially Balanced Incomplete Block Design. A principal result is that such a composition of a design having g associate classes with one having f classes yields a Partially Balanced Incomplete Block Design having at most $g+f+gf$ classes.

6. *A discussion of Robinson's non-standard model of the reals*, by J. B. Deeds, Louisiana State University.

7. *A simple method for evaluating the determinant of a square matrix*, by J. O. Koehl, University of Southwestern Louisiana.

The method proposed for the evaluation of a square determinant is a simple means which eliminates the expansion into minor determinants and permits the user to quickly obtain the answer. The method and proof are elementary and can easily be done in an introduction to determinants.

8. *Congruence without measure*, by D. R. Hester, Nicholls State College.

Congruence of two line segments is taken as a primitive notion and is characterized by postulates. Continuity of a line is postulated and several basic theorems concerning betweenness of points are assumed. A two term order relation for line segments is defined such that if AB and CD are two line segments, and if there is a point Q between points C and D such that segment AB is congruent to segment CQ, then segment AB is said to be less than segment CD. It is then shown that: (1) a segment is never less than itself, (2) given a point B between points A and C, then segment AB is less than segment AC, (3) if a first segment is congruent to a second segment, and the second segment is less than a third segment, then the first segment is less than the third, and (4) if a point B lies between points A and C, and if segment AC is congruent to segment $A'C'$, then there is a point B' such that segment AB is congruent to segment $A'B'$, and point B' lies between points A' and C'.

9. *Report on International Congress of Mathematicians, Moscow, August, 1966*, by Margaret M. LaSalle, University of Southwestern Louisiana.

This report included a synopsis of the outstanding mathematical work done by the Award Winners for discovery and generalization of meta-mathematical and algebro-geometric theorems. The Congress and trips to Moscow and Leningrad were outstanding events with excellent balance provided in intellectual, social, and cultural pursuits.

L. VIRGINIA CARLTON, *Secretary-Treasurer*

MARCH MEETING OF THE OKLAHOMA-ARKANSAS SECTION

The annual spring meeting of the Oklahoma-Arkansas Section of the MAA was held on March 31 and April 1, 1967 at Northeastern State College, Tahlequah, Oklahoma. There were 114 persons registered, of whom 76 were members of the Association.

Dr. James Scroggs of the University of Arkansas presided at the business session on Saturday morning. Dr. James Nickel reported that approximately 3800 high school students from the Oklahoma-Arkansas section participated in the MAA High School Contest. The section went on record expressing its appreciation to Dr. Nickel for his work with the high school contest.

Dr. R. B. Deal, representative on the Board of Governors, gave a report on the activities of the Board. Dr. James Scroggs reported on the Sectional Officers meeting held in August at Rutgers University.

A resolution, offered by Dr. Gene Levy, commending the National Science Foundation for its institute programs and urging their continuance was passed without dissent.

The meeting in 1968 will be at the Federal Aviation Agency in Oklahoma City, and the 1969 meeting will be at Arkansas State University at Jonesboro.

Officers elected for 1967–68 were: Chairman, Herbert Monks of Northeastern State College; Vice-Chairman, John Reiger of Federal Aviation Agency; Secretary-Treasurer, Harold Huneke of The University of Oklahoma.

The Saturday session was devoted to the following invited papers:

1. *A computer simulation of atrial fibrillation*, by Thomas Cairns, University of Tulsa.

6. *A discussion of Robinson's non-standard model of the reals*, by J. B. Deeds, Louisiana State University.

7. *A simple method for evaluating the determinant of a square matrix*, by J. O. Koehl, University of Southwestern Louisiana.

The method proposed for the evaluation of a square determinant is a simple means which eliminates the expansion into minor determinants and permits the user to quickly obtain the answer. The method and proof are elementary and can easily be done in an introduction to determinants.

8. *Congruence without measure*, by D. R. Hester, Nicholls State College.

Congruence of two line segments is taken as a primitive notion and is characterized by postulates. Continuity of a line is postulated and several basic theorems concerning betweenness of points are assumed. A two term order relation for line segments is defined such that if AB and CD are two line segments, and if there is a point Q between points C and D such that segment AB is congruent to segment CQ, then segment AB is said to be less than segment CD. It is then shown that: (1) a segment is never less than itself, (2) given a point B between points A and C, then segment AB is less than segment AC, (3) if a first segment is congruent to a second segment, and the second segment is less than a third segment, then the first segment is less than the third, and (4) if a point B lies between points A and C, and if segment AC is congruent to segment $A'C'$, then there is a point B' such that segment AB is congruent to segment $A'B'$, and point B' lies between points A' and C'.

9. *Report on International Congress of Mathematicians, Moscow, August, 1966*, by Margaret M. LaSalle, University of Southwestern Louisiana.

This report included a synopsis of the outstanding mathematical work done by the Award Winners for discovery and generalization of meta-mathematical and algebro-geometric theorems. The Congress and trips to Moscow and Leningrad were outstanding events with excellent balance provided in intellectual, social, and cultural pursuits.

L. VIRGINIA CARLTON, *Secretary-Treasurer*

MARCH MEETING OF THE OKLAHOMA-ARKANSAS SECTION

The annual spring meeting of the Oklahoma-Arkansas Section of the MAA was held on March 31 and April 1, 1967 at Northeastern State College, Tahlequah, Oklahoma. There were 114 persons registered, of whom 76 were members of the Association.

Dr. James Scroggs of the University of Arkansas presided at the business session on Saturday morning. Dr. James Nickel reported that approximately 3800 high school students from the Oklahoma-Arkansas section participated in the MAA High School Contest. The section went on record expressing its appreciation to Dr. Nickel for his work with the high school contest.

Dr. R. B. Deal, representative on the Board of Governors, gave a report on the activities of the Board. Dr. James Scroggs reported on the Sectional Officers meeting held in August at Rutgers University.

A resolution, offered by Dr. Gene Levy, commending the National Science Foundation for its institute programs and urging their continuance was passed without dissent.

The meeting in 1968 will be at the Federal Aviation Agency in Oklahoma City, and the 1969 meeting will be at Arkansas State University at Jonesboro.

Officers elected for 1967–68 were: Chairman, Herbert Monks of Northeastern State College; Vice-Chairman, John Reiger of Federal Aviation Agency; Secretary-Treasurer, Harold Huneke of The University of Oklahoma.

The Saturday session was devoted to the following invited papers:

1. *A computer simulation of atrial fibrillation*, by Thomas Cairns, University of Tulsa.

contributions to the theory of coloring maps. It treats several related areas such as the coloring of maps on surfaces of higher genus, Tait's conjecture and Petersen's theorem.

8. *On some definite integrals involving trigonometrical functions*, by Tetsundo Sekiguchi and Naoki Kimura, University of Arkansas, Fayetteville.

We shall deal with the integral $\int_0^\infty [(\sin^m x \cos^n x)/x^p]dx$ and generalizations to several directions by making use of only elementary methods.

9. *On ordered sets with some finitary conditions*, by Naoki Kimura, University of Arkansas, Fayetteville.

Relations between ordered sets and projective semilattice generated by them will be settled.

10. *Time-optimal controls of the equation of evolution in a separable and reflexive Banach space*, by J. K. Cole, University of Oklahoma, Norman.

11. *An oscillation theorem for a nonlinear second order differential equation*, by John Hooker, University of Oklahoma, Norman.

H. V. HUNEKE, *Secretary-Treasurer*

MAY MEETING OF THE MINNESOTA SECTION

The spring meeting of the Minnesota Section of the MAA was held at St. John's University in Collegeville, on May 6, 1967. There were 110 persons in attendance, including 92 members of the Association. Professor J. E. Lange of St. John's University presided over the morning session; Professor Dale Varberg of Hamline University presided over the afternoon session. The sessions were held in the Science Center.

At the business meeting, R. J. Dowling of the University of Manitoba was elected Chairman; Rev. Walbert Kalinowski of St. John's University was elected Secretary-Treasurer; Sylvan Burgstahler of the University of Minnesota, Duluth, and D. A. Storvick of the University of Minnesota, Minneapolis, were elected to the Executive Committee. A report was given on the Minnesota High School examination contest. This was followed by a report on the Putnam examination. Finally, the report of the Committee which had examined the CUPM recommendations for the college curriculum was given by the chairman Murray Braden. The report was accepted by the section.

The program of the sessions was as follows:

1. *Biorthogonal polynomials suggested by the Laguerre polynomial*, by Joseph Konhauser, University of Minnesota, Minneapolis.

2. *Some a priori estimates for the Riemann mapping function for a star shaped domain with a cone property*, by J. R. Cannon, Carleton College.

3. *A differential equation in life contingencies*, by F. C. Smith of George V. Stennes and Associates.

4. *Mnemonics for curvature and Christoffel symbols*, by L. E. Bragg, University of Minnesota, Minneapolis.

5. *Another solution of the Morley triangle problem*, by C. N. Mills, Sioux Falls College (Charter Member of MAA).

6. *Some new applications of generating series*, by Leo Moser, University of Alberta (by invitation).

7. *Generalization of the Cauchy integral test*, by Eugene Hobbs, St. Olaf College (introduced by O. E. Stanaitis).

8. *Remarks on theorems of Fort and Schuster*, by G. U. Brauer, University of Minnesota, Minneapolis.

9. *Reaction of the Minnesota Section to the CUPM Report*, by Murray Braden, Macalester College.

WALBERT KALINOWSKI, *Secretary-Treasurer*

MAY MEETING OF THE WISCONSIN SECTION

The annual meeting of the Wisconsin Section of the MAA was held at St. Norbert College in West DePere, on May 6, 1967. Chairman Sister Madeleine Sophie of Alverno College, Milwaukee, presided. Approximately 150 persons attended. The morning session was devoted to a short business meeting and the presentation of several short papers.

During the business meeting, Professor E. F. Wilde of Beloit College, Beloit, was elected Chairman, Dr. J. A. Raab of Wisconsin State University, Oshkosh, was elected Vice-Chairman, and Dr. R. W. Christensen of Wisconsin State University, La Crosse, was elected Secretary-Treasurer.

The remainder of the morning session was devoted to the presentation of the following papers:

1. *Variations on the Dance Problem*, by R. A. Brualdi, University of Wisconsin, Madison.

The following "dance problem" was formulated and solved many years ago: Suppose m boys and m girls attend a dance and that each boy knows exactly k girls and each girl knows exactly k boys. Without making further introductions, is it possible to pair the boys and girls so that each person dances with an acquaintance? Not only is the answer affirmative, but in precisely k dances it is possible for each person to have danced with everyone of his or her acquaintances. When no restrictions are placed on the number of acquaintances of each person, the maximal number of dances possible so that no person dances with an acquaintance more than once is known. (Assuming there are no wallflowers at any dance.) What if the dance hall is small and only r couples can dance at a time? This question is treated and results analogous to the "uncrowded" dance hall are obtained.

2. *Some properties of the algebra of functions vanishing at infinity*, by R. E. Mullins, Marquette University, Milwaukee.

Let $\overline{X}$ denote a σ-compact, locally compact Hausdorff space, $B(X)$ the algebra of bounded complex-valued continuous functions on $\overline{X}$ and $C_0(\overline{X})$ the algebra of functions in $B(\overline{X})$ vanishing at infinity. An algebra A is said to satisfy (P) if $\{x \in \overline{X} : f(x) = 1\}$ is compact for all f in A. It is shown that every closed algebra of real-valued functions satisfying (P) must be contained in $C_0(\overline{X})$. An example is given to show this is not true for complex-valued functions. A Zorn's lemma argument shows there can be many algebras other than $C_0(\overline{X})$ maximal with respect to (P). The distinguishing property of $C_0(\overline{X})$ is that it is the *unique* closed sub-algebra of $B(\overline{X})$ maximal with respect to (P).

3. *Some thoughts on prime numbers*, by Merrill Barnebey, Wisconsin State University, La Crosse.

A brief historical presentation of prime number theory, punctuated with a few suggestions of how to regard prime numbers, is given. The expectation of orderly arrangement of the primes may be due more to psychology than to mathematics. To look for much structure on the set of primes is a little like trying to study the laws of combustion by poking around in the ashes. Even so, some limited pattern is seen.

4. *On a property of the quaternion group*, by C. P. Seguin, Beloit College, Beloit.

In the quaternion group the cosets modulo the center Z, excluding the coset consisting of the center itself, are precisely the conjugate classes consisting of more than one element. The speaker proved the following:

Let G' denote the commutator subgroup of a group G, $C(X)$ the centralizer of the element x, $|C(x)|$ the order of the centralizer and $(G:Z)$ the index of the center. A group G has the property mentioned above if and only if $G' = Z$ and $|C(x)| = (G:Z)$ for each element $x \notin Z$; furthermore, any such group is a p-group.

5. *A convergence theorem for continued fractions*, by W. A. Sanders, Wisconsin State University, Platteville.

In this paper, a rough sketch of the parabola theorem by H. S. Wall was given. This theorem characterizes completely all convergence sets for the continued fraction $1/1+ a_2/1+ a_3/1+ \cdots$ which are symmetric with respect to the real axis. The theorem which was proved was the following: A set of points, S, in the complex plane, which is symmetrical with respect to the real axis, is a convergence set for the continued fraction $1/1+ a_2/1+ a_3/1+ \cdots$ if, and only if, S is a bounded set contained in the parabolic domain $|Z| - R|Z| \leq 1/2$.

6. *The Bayesian approach to statistics*, by D. R. Lund, Wisconsin State University, Eau Claire.

A few of the salient features of the Bayesian approach to statistical inference are pointed out. Under this approach, which is based on the well-known theorem of Thomas Bayes, parameters in a probability model are themselves allowed to have probability distributions. This makes it possible for an experimenter to inject his opinions about the parameters into an analysis through a prior distribution, and inferences about the parameters are then made from a posterior distribution. Two examples are utilized to illustrate the approach.

The afternoon session began with the viewing of the MAA films "Let's Teach Guessing," by George Polya and "Predicting at Random" by David Blackwell. It concluded with a panel discussion with Creighton Buck on the CUPM publication, "A General Curriculum in Mathematics for Colleges."

R. W. CHRISTENSEN, *Secretary-Treasurer*

INCREASES IN MAA CHARGES

At the Houston meeting in January of this year, the bylaws of the Association were amended to provide that dues of individual members be increased to $8 effective with 1968 dues. As was explained in the announcement of the proposed amendment, the need for the increase arose in part from the general economic inflation and in part from the increased cost of providing additional services required by the expansion in Association activities.

At the Toronto meeting and earlier, the Finance Committee and the Board of Governors took appropriate action to increase other charges so that the Association might derive additional income from sources other than members dues. Some of these increased charges are as follows:

Prices of volumes of Carus Monographs and MAA Studies were increased from $2 to $3 for members and from $4 to $6 for nonmembers on July 1, 1967.

Effective January 1, 1968, subscriptions to the AMERICAN MATHEMATICAL MONTHLY will be increased from $10 to $15, and subscriptions to MATHEMATICS MAGAZINE will be increased from $3 for one year to $4 for one year, $7 for two years and $10 for three years. At the same time, the special subscription rate to MATHEMATICS MAGAZINE for MAA members and members of Mu Alpha Theta will be increased from $5 to $6 for a two-year subscription.

Annual dues of academic members will be increased from $25 to $50 also effective with 1968 dues.

Effective July 1, 1968, the price of back numbers of the MONTHLY including Slaught Memorial Papers, the Dunkel Problem Book, and the Fiftieth Anniversary Issue will be increased from $1.50 to $2.00 per copy, with a special rate of $1.50 each for purchases of five or more Slaught Papers.

Increases in advertising rates for the MONTHLY and MATHEMATICS MAGAZINE will not be made this year since these rates were increased in the summer of 1966. It is expected that these rates will be increased again in the summer of 1968.

In brief, those responsible for the finances of the Association have taken actions to increase income so that the dues of individual members may be kept as low as possible.

HARRY M. GEHMAN, *Treasurer*

CALENDAR OF FUTURE MEETINGS

Fifty-first Annual Meeting, San Francisco Hilton, California, January 25–27, 1968.

Forty-ninth Summer Meeting, University of Wisconsin, Madison, Wisconsin, August 26–28, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, Indiana University of Pennsylvania, Indiana, April 27, 1968.

FLORIDA, Miami Dade Junior College, South Campus, Miami, March 22–23, 1968.

ILLINOIS, Southern Illinois University, Edwardsville Campus, May 10–11, 1968.

INDIANA

IOWA, Wartburg College, Waverly, April 19, 1968.

KANSAS, Marymount College, Salina, Spring 1968.

KENTUCKY, University of Kentucky, Lexington, Spring 1968.

LOUISIANA-MISSISSIPPI, Broadwater Beach Hotel, Biloxi, Mississippi, February 16–17, 1968.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA, Morgan State College, Baltimore, December 9, 1967.

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA

MISSOURI, Lindenwood College, St. Charles, April 27, 1968.

NEBRASKA, Nebraska Center for Continuing Education, Lincoln, April 26–27, 1968.

A SURVEY OF MATHEMATICS
Elementary Concepts and Their Historical Development

VIVIAN SHAW GROZA, Sacramento City College

Designed for students with little or no background in mathematics, this text uses a historical framework to introduce the various branches of mathematics and to develop an appreciation and understanding of the relationship of mathematics to the modern world.

March 1968 352 pp. $7.95 (tent.)

INTRODUCTION TO COLLEGE MATHEMATICS

VINCENT H. HAAG and DONALD W. WESTERN, both of Franklin and Marshall College

Providing a solid background for courses in calculus, linear or abstract algebra, and finite mathematics, this text establishes a natural progression of mathematical ideas rather than a succession of isolated topics. Logic, sets, and mappings are used as a basis for analyzing the different branches of mathematics and the structures that underlie them.

March 1968 640 pp. $8.95 (tent.)

INTRODUCTION TO THE THEORY OF ABSTRACT ALGEBRAS

RICHARD S. PIERCE, New Mexico State University

This new graduate text provides a thorough treatment of modern set theory, the basic definitions of abstract algebra theory, and the major theorems of universal algebra. Emphasizing applications of the theory, the author also presents some of the fundamental representation theorems of Boolean algebras, distributive lattices, and lattice-ordered groups and rings. (**Athena** Series)

May 1968 160 pp. $6.95 (tent.)

MATRICES AND LINEAR ALGEBRA

HANS SCHNEIDER and GEORGE P. BARKER, both of the University of Wisconsin, Madison

Intended for students of mathematics as well as of other disciplines, this book combines concrete aspects of the subject with more abstract facets to provide a balance not found in other texts. While matrices are emphasized, a chapter is devoted to linear transformations.

February 1968 352 pp. $7.00 (tent.)

Holt, Rinehart and Winston, Inc.
383 Madison Avenue, New York, N.Y. 10017

The January, 1967 issue of *The American Mathematical Monthly* reprinted Professor Nura D. Turner's paper entitled "National Aspects of the MAA-SA Contest in the Development of Talent," which was originally presented at the International Congress of Mathematicians in Moscow in 1966. One of the conclusions that Professor Turner drew after a study of the academic and professional progress of 117 outstanding mathematics students was: "There is a weakness in teaching mathematics at the calculus level, both elementary and advanced. Too many mathematics students are turning to other fields at this point. Students have been frank in saying this has been where they have lost interest."

Although numerous calculus texts appear on the market each year, they generally accept a more or less standard course content, and either rearrange the order of topics or offer some improvements on the way the topics are presented.

In the preface of his recently published text POLYNOMIALS, POWER SERIES, AND CALCULUS, Professor Howard Levi of Hunter College of The City University of New York has this to say about the problem: "The whole situation suggests that the course itself is at fault and that no text for it can be satisfactory. This text is designed for a *new* course in analysis, covering the calculus of functions of one variable, but having a mathematical base which differs from the traditional. Specifically, it builds the course around the notion of *best approximating polynomials, deemphasizes limits of functions and derivatives,* and *omits the Riemann integral entirely* (obtaining all its usual applications in the other ways)."

POLYNOMIALS, POWER SERIES, AND CALCULUS

For a logical approach to computing–

COMPUTERS: Introduction to Computers and Applied Computing Concepts

By CHARLES H. DAVIDSON *and* ELDO C. KOENIG, *both of the University of Wisconsin.*

This unique survey, requiring only high school mathematics, provides broad but intensive coverage of computers. The authors employ a gradual, logical approach to the subject, explaining clearly what computers are, what their uses are, how to "talk" to computers, and the extent of their social and economic implications.

Elementary FORTRAN programming is introduced at an early point, after which various areas of application are illustrated by developing simple FORTRAN programs. The methods of handling basic computer problems in areas such as mathematics, control systems, sorting, and inventory management are discussed in detail. *1967. 596 pages. $10.95.*

BASIC PROGRAMMING

By JOHN G. KEMENY *and* THOMAS E. KURTZ, *both of Dartmouth College.*

An introduction to computer programming employing BASIC—the new computer language which enables the novice to learn programming quickly and easily.

Part I contains an elementary BASIC programming course. Part II applies programming to a variety of fields. Mathematical areas range from high school mathematics and elementary number theory to simulation and games, calculus, elementary statistics, vectors and matrices. Unique features are over 100 BASIC programs and coverage of the new time-sharing computer system. *1967. 122 pages. $4.95.*

DIFFERENTIAL EQUATIONS

This solid text stresses broad outlook rather than specifics: mathematical understanding rather than the acquisition of many techniques. Starting with linear equations, the text proceeds through numerical methods, Picard's Existence Theorems, operational techniques, and ends with a chapter on physical applications.

By MARTINUS ESSER of University of Dayton. About 225 pages. Illus. About $8.00. *Ready January, 1968*

Heider & Simpson *New*

THEORETICAL ANALYSIS

This text for undergraduate courses in real variables incorporates the recommendations of the CUPM and lucidly presents such topics as: real numbers, complex numbers, set theory, metric spaces, euclidian spaces, continuity, differentiation and the Riemann-Stieltjes integral. The authors first emphasize fundamentals and the construction of proofs to lead the student from his earlier understanding of computational techniques to a deeper understanding of theory. They then take up advanced topics, including Lebesgue integration and the spaces, R^n, L^p and $C(X)$.

By the late L. J. HEIDER, formerly of Marquette Univ., and J. E. SIMPSON of the Univ. of Kentucky. 379 pages. Illus. $8.50. *Published July, 1967*

PROBLEMS IN PROBABILITY, STATISTICS & RANDOM VARIABLES

Here is an outstanding collection of problems emphasizing many modern applications: automatic control, processing of experimental data, etc. Each section is introduced by a synopsis of the theory necessary to solve the problems which follow. Instructive exercises are included in the areas of *random events, entropy and information, limit theorems* and *Markov processes.* These are followed by answers and when needed, by helpfully detailed solutions.

By A. A. SVESHNIKOV. About 630 pages. About $12.00. *Ready February, 1968*

Owen *New*

GAME THEORY

Providing extensive coverage of game theory, this superb new book offers a systematic exposition of two-person games with their methods of solution, as well as solution concepts for n-person games. You will find clear descriptions and sharp analyses of—*differential games —the bargaining set—games for a continuum of players—games without side payments—games in partition function form.*

Multi-stage, two-person games, usually ignored in other texts, are lucidly described. N-person games which seldom receive more than cursory treatment are given detailed coverage in this volume.

Although the author approaches the subject from the point of view of a mathematician, he has not ignored the implications for the social scientist: heuristic justifications are given wherever possible.

By GUILLERMO OWEN of Fordham Univ. About 210 pages. Illus. About $9.00. *Ready January, 1968*

Modern Texts for Modern Courses

MATHEMATICS FROM McGRAW-HILL

FOUNDATIONS OF CONSTRUCTIVE ANALYSIS. By ERRETT BISHOP, University of California, San Diego.
McGraw-Hill Series in Higher Mathematics

This forward-looking, graduate-level book can be recommended for several pedagogical uses: as a text in constructive mathematics; as supplemental material in courses in logic and philosophy; as a text in courses in functional analysis, abstract analysis, combined real and complex analysis. All ranks of mathematicians desiring a new approach will find this book of essential interest.

The book aims to revitalize the constructionist approach, in which every theorem shows how certain computations within the set of integers will produce certain results. This is a relatively new field, in that most current math does not interest itself in definable results of finitely performable operations. Having made its premise, the greater part of this text gives it validity by developing abstract analysis according to the constructive precepts expressed.

384 pp., $12.00

THEORY OF RECURSIVE FUNCTIONS AND EFFECTIVE COMPUTABILITY. By HARTLEY ROGERS, JR., M.I.T.
McGraw-Hill Series in Higher Mathematics

Using an informal, intuitive approach, this book presents the theory of the most "effective" (mechanically computable) mathematical procedure. It is especially useful in one- and two-semester courses in *Recursive Functions, Turning Machine Capability, Topics in Mathematical Logic, Advanced Logic, Foundations of Mathematics, Theory of Heirarchies,* at the graduate or upper class level, in Departments of Mathematics, Philosophy, or Computer Science.

Much of the material gathered here and unified in treatment exists otherwise only in scattered mathematical journals, where they vary widely in approach, terminology and notation. The author points out that, "It is possible for one who possesses a good grasp of the simple, primitive ideas of our theory to do research just as it is possible for a student of elementary algebra in school to do research in the theory of natural numbers."

More than 650 exercises are graded for difficulty, cross-referenced with the texts and contain a variety of additional, substantial material. **Off Press**

INTEGRALS AND OPERATORS. By IRVING E. SEGAL, M.I.T.; RAY A. KUNZE, Washington University.
McGraw-Hill Series in Higher Mathematics

This text takes a contemporary approach explaining the origin and general scientific significance of the subjects treated. In particular, it does not merely train the student in doing certain kinds of exercises, or load him up with useful theorems; it is designed to help him feel that he understands what integration theory is *all about.*

INTEGRALS AND OPERATORS is a graduate level text, eminently suitable for a first course in real analysis focused on integration theory. Such a course might be entitled *Measure and Integration, Measure Theory,* or *Advanced Analysis.* The student should be familiar with the elementary aspects of set theory, general topology, and algebra, and should have some training in rigorous analysis.

The book leads the student rather rapidly, but not at all abruptly through one of the most central (and previously considered most difficult) areas of modern functional analysis—the spectral theory of operators in Hilbert space.

Both the general theory and many examples and illustrative exercises are provided. In addition, each major subject is introduced with much general orientation in relation to modern mathematics. **Winter**

ANNOUNCING 1967-1968 Texts

From Allyn and Bacon, Inc.

470 Atlantic Avenue, Boston, Massachusetts 02210

INTRODUCTION TO COMPLEX ANALYSIS, Revised Edition

By Zeev Nehari, Carnegie Institute of Technology. Nov. 1967. Designed for a one-semester advanced undergraduate course. Again featuring the clear and precise style and the careful balance of theory and technique of the first edition, this revision comprises three major changes: 1. New exercises, 2. Complete revision of the material on Gauchy's theorem, 3. Proof of the Riemann mapping theorem. Est. 288 pp.

INTRODUCTORY CALCULUS AND ANALYTIC GEOMETRY

By John A. Tierney, U. S. Naval Academy. Feb. 1968. "The author feels that the majority of present texts . . . make little attempt to promote basic understanding of fundamental concepts . . . they are written at a highly sophisticated mathematical level which discourages all but the most brilliant students. . . . This is an attempt to produce a book which has a mathematical flavor but which is not at the same time a text on advanced calculus and functions of a real variable." From the Preface. Est. 650 pp.

INTRODUCTION TO MODERN ALGEBRA, Revised Edition

By Neal H. McCoy, Smith College. March, 1968. Important algebraic systems are introduced slowly and carefully with special attention to points which might cause difficulty in senior or graduate level courses. The text proceeds from rings to integral domains to fields, with numerous illustrations of each concept as it is introduced. Est. 384 pp.

BASIC COLLEGE ALGEBRA, Second Edition

By Julian D. Mancill and Mario O. Gonzalez, both of the University of Alabama. April, 1968. The central theme of the first edition, mathematical completeness and directness with a reasonable level of rigor, is maintained. Essentially this text: 1. develops the real and complex number systems; 2. reviews elementary algebra; and 3. treats the conventional mathematical applications of elementary algebra.

Future 1968 Publications:

COLLEGE AND UNIVERSITY MATHEMATICS: A FUNCTIONAL APPROACH; by Donald R. Barr, U. S. Naval Postgraduate School; and Lloyd E. Willmore, Wisconsin State University at Oshkosh.

LINEAR ALGEBRA: AN INTRODUCTORY APPROACH, Second Edition; by Charles W. Curtis, University of Oregon.

INTRODUCTORY MATHEMATICAL ANALYSIS, Third Edition; by Edgar D. Eaves, University of Tennessee; and Robert L. Wilson, Ohio Wesleyan University.

CALCULUS WITH ANALYTIC GEOMETRY, Fourth Edition; by Richard E. Johnson, University of New Hampshire; and Fred L. Kiokemeister, Mt. Holyoke College.

Major New Texts from Macmillan

MODERN CALCULUS WITH ANALYTIC GEOMETRY
Volumes I and II
By A. W. Goodman, University of South Florida

Mathematical rigor, clarity of expression, and lively, imaginative language make this an excellent text for the calculus sequence. All important theorems are proved—without embellishment and with ample discussion to make each step clear. Outstanding features include the author's treatment of real numbers, and emphasis on vectors, and an excellent series of appendices. Volume I covers single-variable calculus and Volume II covers multi-variable calculus, linear algebra, and differential equations.

Volume I: 1967, 808 pages, $10.95
Volume II: 1968, approx. 512 pages, prob. $9.95

ALGEBRA
By Saunders Mac Lane, The University of Chicago, and
Garrett Birkhoff, Harvard University

A fresh presentation of algebra for undergraduate or graduate courses, and the first to make full and effective use of the new concepts of category, functor, and "universal elements" for functors. The standard material on the integers, groups, rings, and fields, is thus treated in uniform fashion. The basic concept of a module is used to develop linear and multilinear algebra through eigenvalues, rational and Jordan canonical forms, and tensor and exterior algebra. Special topics include affine geometry, lattice theory, and the notion of an adjoint functor, which dominates so much of current developments in algebra.

1967, 598 pages, $11.95

TRIGONOMETRY: An Analytic Approach
By Irving Drooyan and Walter Hadel, both of Los Angeles
Pierce College

Concepts and notations as well as a review of the real number system are presented in the first chapter of this thoroughly modern text. Each of the chapters contains graded exercises designated "A," "B," and "C," to permit greater instructional flexibility. A second color is used functionally throughout. Available gratis are a Teacher's Supplement, and Solutions Manual. Progress Tests are also available.

1967, 308 pages, $5.50

MATHEMATICS FOR ELEMENTARY SCHOOL TEACHERS
By Helen L. Garstens and Stanley B. Jackson, both of the
University of Maryland

Written for the practicing and prospective elementary school teacher, this textbook presents a sound exposition of the basic concepts of elementary school mathematics—number and measure. A great number of pedagogical aids that stress the deductive nature of mathematics make the book quite teachable. A Teacher's Manual is also available.

1967, 500 pages, $9.95

MODERN PLANE GEOMETRY FOR COLLEGE STUDENTS
By Herman R. Hyatt and Charles C. Carico, both of
Los Angeles Pierce College

This modern text for one semester courses meets the needs of both the terminal student and the student who will proceed to further mathematical studies. A careful distinction is made between geometric entities and their measures and the concept of "proof" is given special attention. "A" or "A" and "B" sets of problems permit the instructor to use the text effectively in either three or five semester-hour courses. A second color is used to illustrate ideas. Answers to odd-numbered problems appear in the appendix, and a Solutions Manual is available, gratis.

1967, 414 pages, $7.95

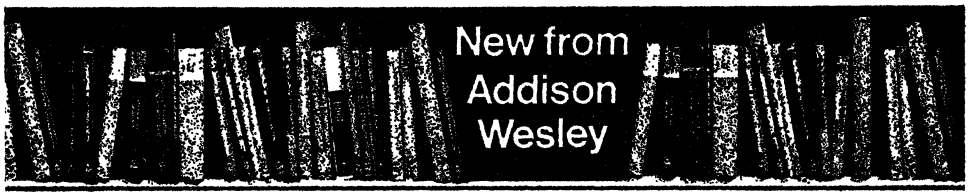
important new math books from *Harper & Row*

THE CALCULUS with Analytic Geometry

LOUIS LEITHOLD



THE CALCULUS with Analytic Geometry is a full treatment of elementary calculus which presents the theory in a well-motivated and rigorous fashion without overlooking the computational aspects of the subject. The author has written this text with a respect for the needs of the student. Throughout the development, complete rigor is maintained, but rigor that is tempered by lucid textual commentary and motivation, which is further amplified by specially chosen examples. It is also the author's concern that the student see, and master, the computational aspects of calculus which are of great importance in other work. Exercises contain not only drill on the computational processes developed, but also more theoretically oriented problems designed to bring out still more the significance of the results obtained. *Coming January.*

INTRODUCTION TO CALCULUS

DONALD GREENSPAN

For a first course in calculus, this revolutionary text, which develops calculus with the same rigor accorded to other mathematical subjects, reflects the vast impact which modern physics and modern high speed computing have had on all the scientific disciplines. Discrete geometrical and physical concepts are studied with an awareness of high speed computer capabilities. Continuous geometrical and physical concepts are developed by applying limiting procedures to discrete ones. Thus the author not only covers the usual material on limits, derivatives, integrals, series, and first and second order differential equations, but also develops—with equal emphasis—theory, techniques, and applications relating to discrete functions, difference quotients, finite sums, and nonlinear difference equations. Such vital concepts and topics as quantized time and motion, discrete model theory, and interval arithmetic are developed and applied for the first time in any calculus text. Illustrative examples; end-of-chapter exercises. *Coming January.*

CALCULUS OF ONE VARIABLE

by

JOSEPH W. KITCHEN, JR.

Duke University

Intended for a first-year honors course in calculus, this book covers the calculus of functions of a single real variable, also treating analytic geometry and infinite series. The book follows CUPM recommendations for such a course, in spirit if not in specific detail.

The author's objective is to provide a richly textured, flexible text with a great variety of attractive options in addition to a solid core of standard material. The book's starting point is the characterization of the real numbers as a complete ordered field; the development of calculus which then follows is quite rigorous. The basic topics of limits and inequalities also receive an unusually thorough treatment. The rigor maintained throughout does not, however, slight the importance of intuition and heuristic reasoning. Illustrative examples and figures abound, and problems of all types and at all levels of difficulty are provided.

CONTENTS: Preliminaries. Analytic geometry of straight lines and circles. Limits. The technique of differentiation. Completeness of the real numbers. Mean value theorems and their applications. Antidifferentiation and its applications. The Riemann integral. Transcendental functions. Technique of integration. Higher order mean value theorems. Plane curves. Infinite series.

REPORTS AND ANNOUNCEMENTS OF THE ASSOCIATION AND ITS SECTIONS

MEETINGS AND ANNOUNCEMENTS OF THE ASSOCIATION

Academic members elected into the Association, H. L. ALDER, 476, 1176.
Announcement of L. R. Ford Awards, H. L. ALDER, 908.
Employment register, 625, 1177.
Fiftieth annual meeting of the Association, H. L. ALDER, 466–473.
Forty-eighth summer meeting of the Association, H. L. ALDER, 1168–1176.
Increases in MAA charges, 1183.
MAA publications, 482–483.
Move of MAA Central Office to Washington, 1176.
New Sectional Governors of the Association, 893.
Officers and Committees as of February 1, 1967, 476–481.
Professional Opportunities in Mathematics: New edition, 909.
Proposed Amendment to the By-Laws of the MAA, H. L. ALDER, 624–625.
Qualifications for a College Faculty in Mathematics, 908–909.
Reciprocity agreement with Société Mathématique de Belgique, 113.
Report of the Treasurer for the year 1966, 483.
Resolutions voted by Board of Governors, 473–475.
Retired mathematicians, 1177.
Summer dues payments, 769.
Summer employment opportunities, 1177.
The 1967 William Lowell Putnam Mathematical Competitions, 908.
Zipcoding of addresses, 113.

MEETINGS OF ITS SECTIONS

Allegheny Mountain, May 1967, BERTHA W. MATHER, 1039–1042.
Illinois, May 1967, ARNOLD WENDT, 1042–1944.
Indiana, November 1966, GEORGE PEDRICK, 350–351. May 1967, GEORGE PEDRICK, 1044.
Iowa, April 1967, B. E. GILLAM, 1035–1037.
Kansas, April 1967, HELEN KRIEGSMAN, 1037–1038.
Kentucky, April 1967, J. C. EAVES, 1038–1039.
Louisiana-Mississippi, March 1967, L. VIRGINIA CARLTON, 1178–1179.
Maryland-District of Columbia-Virginia, April 1966, G. N. TRYTTEN, 111–112. December 1966, G. N. TRYTTEN, 621–623. April 1967, G. N. TRYTTEN, 894–895.
Metropolitan New York, April 1966, MARY HAGEN, 112. March 1967, THERESA J. BARZ, 1290.
Michigan, March 1967, L. H. SERIER, 893–894.
Minnesota, April 1966, W. C. KALINOWSKI, 481–482. October 1966, W. C. KALINOWSKI, 621. May 1967, W. C. KALINOWSKI, 1181–1182.
Missouri, April 1966, C. A. JOHNSON, 350. April 1967, E. C. PRINGLE, 896.
Nebraska, May 1967, H. M. COX, 1044–1046.
New Jersey, November 1966, F. A. VARRICHIO, 482. May 1967, F. A. VARRICHIO, 1046.
Northeastern, November 1966, G. W. BEST, 351. June 1967, G. W. BEST, 1290.
Northern California, February 1967, G. L. ALEXANDERSON, 623–624.
Ohio, April 1967, FOSTER BROOKS, 896–898.
Oklahoma-Arkansas, March 1967, H. V. HUNEKE, 1179–1181.
Pacific Northwest, June 1967, E. A. MAIER, 1291.

Philadelphia, November 1966, V. V. LATSHAW, 351.
Rocky Mountain, May 1966, W. N. SMITH, 225–228.
Southeastern, April 1967, HENRY SHARP, JR., 898–904.
Southern California, March 1967, R. B. HERRERA, 768–769.
Southwestern, April 1966, E. L. WALTER, 112–113. March 1967, S. T. KAO, 1034–1035.
Texas, April 1967, B. T. GOLDBECK, JR., 904–907.
Upper New York State, May 1967, N. G. GUNDERSON, 1046–1047.
Wisconsin, May 1967, R. W. CHRISTENSEN, 1182–1183.

PERSONAL INFORMATION

The following persons presented papers at meetings of the Association and its Sections:

EDITORIAL CORRESPONDENCE should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with det $[a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are \$6.00 (\$8.00 in 1968). For nonmembers the subscription price is \$10.00 (\$15.00 in 1968).

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

PROJECTIVE PLANES AND ISOTOPIC TERNARY RINGS

G. E. MARTIN, State University of New York at Albany

1. Introduction and summary. This article concerns itself with a certain coordinatization of a projective plane, the ternary systems induced by this coordinatization, and isotopism, an equivalence relation on such algebraic structures. The remainder of this section is a brief summary. All the necessary definitions are included in the text. The article is self-contained.

Two distinct points A and A' are picked in a projective plane. The points not on the special line $l=AA'$ are given coordinates in the standard fashion. Essentially, such a point corresponds to the ordered pair of lines through A and A' which pass through the point. Let l' be a line distinct from l which passes through A. Coordinates are now assigned to the lines not through the special point A in a fashion dual to that for the points. Essentially, such a line corresponds to the ordered pair of points on l and l' which lie on the line.

The incidence relation between the points and the lines of the projective plane determines a ternary system which is not, in general, a Hall ternary ring (HTR). We shall call such a ternary system an intermediate ternary ring (ITR). A planar ternary ring (PTR) is a ternary system which has the same axioms as a HTR without those concerning a zero or unity. Structurally, the ITR lie between the PTR and the HTR. Right and left zeros are defined in the expected way. An ITR has a right zero if and only if it has a left zero, although they may be distinct. Isotopism is defined for ternary systems in the general sense as a composite of four arbitrary permutations on the elements. It turns out that the ITR are exactly the isotopes, in this general sense, of the HTR.

For a summary of related material, *Contributions to Geometry*, Number 4 of the Slaught Memorial Papers of this MONTHLY, is an excellent reference. Other references on projective planes as well as ternary rings include Artzy [2], Blumenthal [3], and Chapter 20 of Hall [4]. Pickert [7] is the standard advanced reference.

2. A coordinatization of a projective plane. A *projective plane* consists of a set whose elements are called points and another set whose elements are called lines together with an incidence relation between the points and lines such that (using the familiar language of geometry to designate the incidence relation): (i) Two points lie on exactly one line. (ii) Two lines intersect in exactly one point. (iii) There exist four points such that no three are collinear. From these axioms it easily follows that there are four lines such that no three are concurrent. This is the dual of the third axiom. The second is the dual of the first. Thus we may assume that the axioms are symmetric with respect to "point" and "line."

From the axioms of a projective plane, it follows that the number of points on any line is equal to the number of lines through any point. If this number is $n+1$, then n is called the *order* of the plane.

We shall give a coordinatization to a projective plane of order n. Let S be any set of cardinality n. Let ∞ be any element which is not in S. We pick two distinct points A and A' in the plane. Let $l=AA'$, the line through A and A'. Let l' be any line through A different from l. Our coordinatization depends on these choices.

To the line l we assign coordinate $[\infty]$. To each line, different from l, through A we assign a coordinate $[x]$ where x is in S. To each line, different from l, through A' we assign a coordinate $[y]'$ where y is in S. In each case the correspondence between the lines and the elements of S is one-to-one and onto. Then to every point P off l we assign coordinates (x, y) if and only if PA is $[x]$ and PA' is $[y]'$.

We shall now dualize the above construction in the following sense. To the point A we assign the coordinate (∞). To each point, different from A, on l we assign a coordinate (m) where m is in S. To each point, different from A, on l' we assign a coordinate $(b)'$ where b is in S. In each case the correspondence between the points and the elements of S is one-to-one and onto. Then to every line t off A we assign coordinates $[m, b]$ if and only if t and l intersect in (m) and t intersects l' in $(b)'$.

Thus every point and line has been associated with at least one type of coordinate. Only the points different from A on l' and the lines different from l through A' have two types of coordinates. Note that the points off l on a line through A all have the same first coordinate, the points off l on a line through A' all have the same second coordinate, the lines off A concurrent on l all have the same first coordinate, and the lines off A concurrent on l' all have the same second coordinate.

3. Planar ternary rings. A *ternary system* $R=(S, \langle\ \rangle)$ is a nonempty set S together with a ternary operation defined on S, i.e., for every ordered triple $\langle abc\rangle$ of elements of S there corresponds a unique element $d=\langle abc\rangle$ of S. A *planar ternary ring* or PTR is a ternary system $(S, \langle\ \rangle)$ such that S has at least two distinct elements and such that for all a, b, c, d in S:

I. $\langle abx\rangle=c$ has a unique solution x in S.

II. $\langle xab\rangle=\langle xcd\rangle$, $a\neq c$, has a unique solution x.

III. $\langle axy\rangle=b$, $\langle cxy\rangle=d$, $a\neq c$, has a solution x and y.

THEOREM 1. *Let a projective plane be coordinatized as above by elements from a set S. Define a ternary operation by $y=\langle xmb\rangle$ if and only if (x, y) is on $[m, b]$. Then $(S, \langle\ \rangle)$ is a PTR.*

Proof. The proof is straightforward. One has only to check I, II, and III in turn.

THEOREM 2. *Let $(S, \langle\ \rangle)$ be a PTR. Then $(S, \langle\ \rangle)$ defines a projective plane as ollows. Points: (x, y), (m), (∞) for every x, y, m in S, ∞ not in S. Lines: $[m, b]$, $[c]$, $[\infty]$ for every m, b, c in S. Incidence: $[\infty]$ contains exactly (∞) and (m) for*

all m in S. $[c]$ *contains exactly* (∞) *and all points* (c, y) *for every* y *in* S. $[m, b]$ *contains exactly* (m) *and all points* (x, y) *for which* $y = \langle xmb \rangle$.

Proof. Again the proof is straightforward. One has only to check the three axioms for a projective plane. The plane in the theorem is called the *plane induced by* $(S, \langle\ \rangle)$.

THEOREM 3. *A solution in* III *is unique.*

Proof. Suppose $\langle axy \rangle = b = \langle auv \rangle$ and $\langle cxy \rangle = d = \langle cuv \rangle$ with $a \neq c$. If $x \neq u$, then $z = a$ and $z = c$ are both solutions of $\langle zxy \rangle = \langle zuv \rangle$, contradicting II. If $x = u$, then $y = v$ by I.

If $R = (S, \langle\ \rangle)$ is a finite PTR, meaning S is a finite set, the "unique" may be omitted from I since the mapping x into $\langle abx \rangle$ is one-to-one if it is onto. Also if R is finite, then III may be omitted from the list as it is implied by I and II. In fact:

THEOREM 4. (Hughes) *If R is a finite ternary system which satisfies* I, *then R satisfies* II *if and only if R satisfies* III *with unique solutions.*

Proof. See Hughes [6].

A *Hall ternary ring* or HTR is a planar ternary ring $(S, \langle\ \rangle)$ with elements 0 and e in S such that for all a, c in S

$$\langle a0c \rangle = \langle 0ac \rangle = c, \qquad \langle ae0 \rangle = \langle ea0 \rangle = a.$$

It must be pointed out that in the literature a HTR is frequently called a "planar ternary ring." The HTR were first studied by M. Hall [5]. D. R. Hughes seems to be the first to have studied the PTR. A proof of the following theorem may be found in Hughes [6].

THEOREM 5. (Hughes) *Let $(S, \langle\ \rangle)$ be a PTR. Let T be a finite subset of S containing at least two distinct elements such that $(T, \langle\ \rangle)$ is a ternary system. Then $(T, \langle\ \rangle)$ is a PTR. Further, if $(S, \langle\ \rangle)$ is a HTR, then so is $(T, \langle\ \rangle)$.*

4. Intermediate ternary rings. Given a PTR$(S, \langle\ \rangle)$ and the projective plane induced by $(S, \langle\ \rangle)$, we have a coordinatization given by Theorem 2 which, in general, may have undesirable properties. We would prefer that points with the same second coordinate be collinear. That is, (a, d) and (c, d) on $[m, b]$ with $a \neq c$ implies (x, d) on $[m, b]$ for all x in S or, equivalently,

IV. $\langle amb \rangle = \langle cmb \rangle = d$, $a \neq c$, implies $\langle xmb \rangle = d$ for all x in S.

We would also prefer that lines with the same second coordinate be concurrent or, equivalently,

V. $\langle mad \rangle = \langle mcd \rangle = b$, $a \neq c$, implies $\langle mxd \rangle = b$ for all x in S.

We shall define an *intermediate ternary ring* or ITR to be a PTR $(S, \langle\ \rangle)$ such that IV and V hold.

The following examples illustrate the independence of the axioms IV and V.

Example 1. $S=\{r, s, t\}$. The tables below give the ternary product $y=\langle xmb\rangle$ on S.

$x = r$

m \ b	r	s	t
r	r	t	s
s	r	t	s
t	r	s	t

$x = s$

m \ b	r	s	t
r	r	t	s
s	s	r	t
t	t	r	s

$x = t$

m \ b	r	s	t
r	r	s	t
s	s	t	r
t	t	s	r

$(S, \langle\ \rangle)$ is a PTR such that both IV and V fail since $\langle rrt\rangle=\langle srt\rangle=s$ but $\langle trt\rangle=t$ and $\langle rrt\rangle=\langle rst\rangle=s$ but $\langle rtt\rangle=t$.

Example 2. $S=\{r, s, t\}$. The entries in the tables above are replaced by:

r t s	r t s	r t s
r t s	s r t	t s r
r s t	t r s	s t r.

$(S, \langle\ \rangle)$ is a PTR such that IV holds. V does not hold since $\langle rrt\rangle=\langle rst\rangle=s$ but $\langle rtt\rangle=t$.

Example 3. $S=\{r, s, t\}$. The entries in the tables above are replaced by:

r t s	r t s	r s t
r t s	s r t	s t r
r t s	t s r	t r s.

$(S, \langle\ \rangle)$ is a PTR such that V holds. IV does not hold since $\langle rrt\rangle=\langle srt\rangle=s$ but $\langle trt\rangle=t$.

Example 4. Let v and w be two distinct elements of a field. Define a ternary operation on S, the set of elements of the field, in terms of the field operations by:

$$\langle xyz\rangle = (x - v)(y - w) + z. \qquad (S, \langle\ \rangle) \text{ is an ITR.}$$

We have seen that in order that the plane induced by a PTR have a coordinatization consistent with that of Section 2, it is necessary that the PTR be an ITR. The question of sufficiency is answered by the next theorem.

THEOREM 6. *Let a projective plane be coordinatized, as in Section 2, by the elements from a set S. Define a ternary operation by $y=\langle xmb\rangle$ if and only if (x, y) on $[m, b]$. Then $(S, \langle\ \rangle)$ is an ITR. Conversely, the plane induced by an ITR has such a coordinatization.*

Proof. At this point we need only prove the second statement. In particular we must recapture A' and l'. $A=(\infty)$ and $l=[\infty]$.

Let $(S, \langle\ \rangle)$ be an ITR, and let b be any element of S. By IV all points with second coordinate b are collinear, say on $[c, d]$. Suppose (s, t) is also on $[c, d]$.

Then $t=\langle scd\rangle$. But $b=\langle scd\rangle$ since, in particular, (s, b) is on $[c, d]$. Hence $t=b$, and we may now say $[c, d]$ is $[b]'$. Likewise for any $g\neq b$, let $[g]'$ be the line containing all points with second coordinate g. So $[b]'$ and $[g]'$ intersect on $[\infty]$ as otherwise they would intersect in a point (x, y) with $y=b=g$. This point of intersection determines $A'=(c)$ uniquely.

Again let b be any element of S. By V all lines with second coordinate b intersect in some point, say (f, d). If $[s, t]$ also passes through (f, d) then $d=\langle fst\rangle$. But $d=\langle fsb\rangle$ as, in particular, $[s, b]$ passes through (f, d). Hence $t=b$ by I. So it is exactly $[f]$ and those lines with second coordinate b which pass through (f, d). Hence (f, d) is $(b)'$. Likewise for any $g\neq b$, all lines with second coordinate g intersect in a point $(g)'$. Thus the line through $(b)'$ and $(g)'$ must pass through A, as otherwise it would have a set of coordinates $[x, y]$ with $y=b=g$. This line determines $l'=[f]$ uniquely.

5. The dual of a ternary system. Two planes π and π' are said to be *dual* if there exists a one-to-one mapping of the points of π onto the lines of π' and a one-to-one mapping of the lines of π onto the points of π' such that a point and line in π are incident if and only if their images are incident in π'.

As we remarked in Section 2, the axioms for a projective plane π are symmetric in "point" and "line." Thus, by interchanging these, we define a plane π' which is dual to π. Let π be the projective plane induced by the PTR $(S, \langle\ \rangle)$. Then it is easy to check that the natural duality is given by:

π	π'	π	π'
(x, y)	$\rightarrow [x, y]$	$[m, b]$	$\rightarrow (m, b)$
(m)	$\rightarrow [m]$	$[a]$	$\rightarrow (a)$
(∞)	$\rightarrow [\infty]$	$[\infty]$	$\rightarrow (\infty)$

However, π' also defines a PTR$(S, \{\ \})$ by (m, b) on $[x, y]$ if and only if $y=\langle xmb\rangle$ if and only if $b=\{mxy\}$. Thus we are led to the following definition.

$(S, \{\ \})$ is said to be the *dual ternary system* of the PTR$(S, \langle\ \rangle)$ if $y=\langle xm\{mxy\}\rangle$ or equivalently $y=\{xm\langle mxy\rangle\}$. It is easy to check that the dual is well defined for any ternary system which satisfies I.

THEOREM 7. *The dual of a PTR is a PTR. The planes induced by a PTR and its dual are dual.*

Proof. The theorem is a direct consequence of the definition and the remarks above.

THEOREM 8. *Let R be a PTR and T its dual. If R satisfies* IV, *then T satisfies* V. *If R satisfies* V, *then T satisfies* IV.

Proof. The selection of the symbols in IV and V has been chosen such that each is the dual of the other.

COROLLARY. *The dual of an ITR is an ITR.*

6. Ternary rings and isotopism. Suppose we have a projective plane coordinatized, as in Section 2, by $(S, \langle\ \rangle)$ where (x, y) on $[m, b]$ if and only if $y = \langle xmb \rangle$. Let α, ρ, σ, and τ be arbitrary permutations on S. If lines $[x]$ through A are renamed $[x^\rho]$ and lines $[y]'$ through A' are renamed $[y^\alpha]'$, then the points (x, y) are renamed (x^ρ, y^α). If the points (m) on l are renamed (m^σ) and the points $(b)'$ on l' are renamed $(b^\tau)'$, then the lines $[m, b]$ are renamed $[m^\sigma, b^\tau]$. Now the new coordinates define a new PTR$(S, \{\ \})$ by (x^ρ, y^α) on $[m^\sigma, b^\tau]$ if and only if $y^\alpha = \{x^\rho m^\sigma b^\tau\}$.

If two ternary systems have the same cardinality, we may assume, without loss of generality, that they are defined on the same set. The remarks in the last paragraph lead us to the following definition. If $(S, \{\ \})$ is a ternary system and α, ρ, σ, τ are arbitrary permutations on S, then the ternary system $(S, \langle\ \rangle)$ defined by

$$\langle xmb \rangle^\alpha = \{x^\rho m^\sigma b^\tau\}$$

for all x, m, b in S is called an *isotope* of $(S, \{\ \})$. The composite of the mappings is called the *isotopism* $(\alpha, \rho, \sigma, \tau)$. If α is the identity permutation, then $(S, \langle\ \rangle)$ is called a *principal isotope*. If $\alpha = \rho = \sigma = \tau$, then the isotopism is called an *isomorphism*.

If $(\alpha, \rho, \sigma, \tau)$ is an isotopism from ternary system R_1 onto R_2 and $(\alpha', \rho', \sigma', \tau')$ is an isotopism from R_2 onto R_3, then $(\alpha\alpha', \rho\rho', \sigma\sigma', \tau\tau')$ is the composite isotopism from R_1 onto R_3. It follows that isotopism and principal isotopism are equivalence relations. An isotopism of a ternary system onto itself is called an *autotopism*. The autotopisms of a ternary system form a group under composition.

THEOREM 9. *Every isotope of a ternary system is isomorphic to a principal isotope.*

Proof. Let $(S, \langle\ \rangle)$ be an isotope of $(S, \{\ \})$ given by $\langle xyz \rangle^\alpha = \{x^\rho y^\sigma z^\tau\}$. Define $(S, [\])$ by $[x^\alpha\ y^\alpha\ z^\alpha] = \{x^\rho y^\sigma z^\tau\}$. Then $(S, [\])$ is a principal isotope of $(S, \{\ \})$ and is isomorphic to $(S, \langle\ \rangle)$.

THEOREM 10. *An isotope of a PTR is a PTR. An isotope of an ITR is an ITR.*

The proof of this last theorem is immediate. Note that it is not true that every PTR is isotopic to some ITR.

THEOREM 11. *If two PTR are isotopic, then the projective planes which they induce are isomorphic.*

Proof. The theorem follows for ITR by the remarks at the beginning of this section. However the correspondences given there, (x, y) corresponds to (x^ρ, y^α) etc., also determine an isomorphism between two planes coordinatized by isotopic PTR.

7. Zeros in a ternary ring. Let $(S, \langle\ \rangle)$ be a ternary system. We shall say z is a *right zero* if $b = \langle xzb \rangle$ for all x, b in S, and we shall say v is a *left zero* if $b = \langle vxb \rangle$

for all x, b in S. z is a *zero* if z is both a right zero and a left zero.

The following properties are immediate in a PTR. A left zero is unique if it exists. z is a right zero if and only if z is a left zero in the dual PTR. A right zero is unique if it exists.

Examples 1, 2, and 3 in Section 4 have neither right zeros nor left zeros. Example 4 has right zero w and left zero v. Let $S=\{r, s, t\}$. Let τ be the permutation on S which interchanges s and t. Define $[xyz]=\langle xyz^{\tau}\rangle$ for x, y, z in S. If $(S, \langle\ \rangle)$ is Example 2, then $(S, [\])$ is a PTR with right zero r but no left zero. If $(S, \langle\ \rangle)$ is Example 3, then $(S, [\])$ is a PTR with left zero r but no right zero.

THEOREM 12. *An ITR has a right zero if and only if it has a left zero.*

Proof. Consider the projective plane induced by the ITR$(S, \langle\ \rangle)$. Then the following statements are each in turn equivalent: z is a right zero. $b=\langle xzb\rangle$ for all x, b. (x, b) on $[z, b]$ for all x, b. $[b]'$ is $[z, b]$ for every b. $(b)'$ is on $[b]'$ for every b where $A'=(z)$ and $l'=[v]$. $(b)'$ is (v, b) for every b. $[m, b]$ through (v, b) for every m, b. $b=\langle vmb\rangle$ for every m, b. v is a left zero.

THEOREM 13. *Let $(S, \langle\ \rangle)$ be an ITR. Let z and v be arbitrary elements of S. Then $(S, \langle\ \rangle)$ has an isotope for which z is a right zero and v is a left zero. Taking $z=v$, the isotope has a zero.*

Proof. Consider the projective plane induced by the ITR$(S, \langle\ \rangle)$. Let σ be any permutation on S which renames points on l such that A' has coordinate (z). Let ρ be any permutation on S which renames the lines through A such that l' has coordinate $[v]$. Let τ be the permutation on S which renames the points on l' such that $(b)'$ is on $[b]'$ for all b. Then, from the proof of the previous theorem, $(S, \{\ \})$ defined by $\langle abc\rangle=\{a^{\rho}b^{\sigma}c^{\tau}\}$ is the required isotope.

THEOREM 14. *Let $R=(S, \langle\ \rangle)$ be a PTR. If R has a right zero z, then $\langle xab\rangle=d$, $a\neq z$, has a unique solution x. If R has a left zero v, then $\langle axd\rangle=b$, $a\neq v$, has a unique solution x.*

Proof. The first result follows from II with $c=z$. The second result follows from III with $c=v$.

COROLLARY. *A ternary system is isotopic to a PTR with a zero if and only if it is an ITR.*

Proof. By Theorem 13, it is sufficient to show that a PTR with a zero is an ITR. In a PTR, a right zero implies IV and a left zero implies V, by Theorem 14. Thus a PTR with a zero is an ITR.

THEOREM 15. *Let $(S, \langle\ \rangle)$ be a PTR with zero 0. Then $(S^*, \cdot)$, where S^* is the set of nonzero elements of S and $\cdot$ is the binary operation defined on S^* by $a\cdot b=\langle ab0\rangle$, is a quasiloop. Also $\langle ab0\rangle=0$ if and only if $a=0$ or $b=0$.*

Proof. Take $z=v=0$ in Theorem 14.

THEOREM 16. *Let* $(S, \langle\ \rangle)$ *be a PTR with a zero. Then any isotope with a zero is isomorphic to an isotope* $(S, \{\ \})$ *defined by*

$$\langle abc\rangle = \{a^\rho b^\sigma c\},$$

where ρ *and* σ *are permutations on* S. *If* $(S, \langle\ \rangle)$ *has zero* 0, *then* $(S, \{\ \})$ *has zero* $0^\rho = 0^\sigma$.

Proof. Let $(S, \langle\ \rangle)$ be a PTR with zero 0. By Theorem 9, any isotope of $(S, \langle\ \rangle)$ is isomorphic to a principal isotope $(S, \{\ \})$ given by $\langle abc\rangle = \{a^\rho b^\sigma c^\tau\}$. In particular, for every x, y, z in S,

$$\{x^\rho 0^\sigma c^\tau\} = \langle x0c\rangle = c = \langle 0yc\rangle = \{0^\rho y^\sigma c^\tau\}.$$

Now $(S, \{\ \})$ has a zero. Setting $y=0$, we have 0^σ is a right zero. Setting $x=0$, we have 0^ρ is a left zero. So the zero of $(S, \{\ \})$ is $z=0^\rho=0^\sigma$. Hence τ is the identity permutation, since $c^\tau = c$ for all c in S.

COROLLARY. *Let* $(S, \langle\ \rangle)$ *be a PTR with zero* 0. *Then any isotope with a zero is isomorphic to an isotope* $(S, [\])$ *with zero* 0 *defined by*

$$\langle abc\rangle^\alpha = [a^\beta b^\gamma c^\alpha],$$

where $\alpha, \beta,$ *and* γ *are permutations on* S *such that* $0^\beta = 0^\gamma = 0$.

Proof. Let α be any permutation on S such that $z^\alpha = 0$, where z is the zero of the isotope $(S, \{\ \})$ given in the proof of the theorem. Let $[a^\beta b^\gamma c^\alpha] = \{a^\rho b^\sigma c\}^\alpha$ where $\beta = \rho\alpha$ and $\gamma = \sigma\alpha$.

Suppose we are given a PTR which is not an ITR and we wish to find an ITR which induces the same projective plane. We have already seen that the two algebraic systems are not isotopic. This problem has been neatly solved by J. R. Wesson. For the proof of the following theorem, see Wesson [9].

THEOREM 17. (Wesson) *Let* $(S, \langle\ \rangle)$ *be a PTR and let* 0 *be any fixed element of* S. *Define* $(S, \{\ \})$ *by*

$$\langle ba\{abc\}\rangle = \langle b0c\rangle$$

and $(S, [\])$ *by*

$$\{ba[abc]\} = \{b0c\}.$$

Then $(S, [\])$ *is a PTR with zero* 0. *The projective planes induced by* $(S, \langle\ \rangle)$ *and* $(S, [\])$ *are isomorphic, and they are dual to the projective plane induced by the PTR* $(S, \{\ \})$.

8. Isotopes of Hall ternary rings. Let $(S, \langle\ \rangle)$ be a PTR with zero 0. We say e is a *left unity* if $\langle ex0\rangle = x$ for all x in S. We say f is a *right unity* if $\langle xf0\rangle = x$ for all x in S. e is a *unity* if e is both a right unity and a left unity. Clearly, if it exists, a left unity or a right unity is unique and different from the zero. Recall that a HTR is a PTR with a zero and a unity.

The following propositions will give us a proof of the fact that a PTR is isotopic to a HTR if and only if it is an ITR.

PROPOSITION 1. *Let R be a PTR with zero 0. Let e be any nonzero element of R. Then R is isotopic to a PTR with zero 0 and left unity e.*

Proof. Let $R=(S, \langle\ \rangle)$. Let σ be the permutation on S defined by $\langle ey0\rangle = y^\sigma$. Define $\{ab^\sigma c\} = \langle abc\rangle$. Then $(S, \{\ \})$ is a PTR with zero 0 and left unity e, since $\{eb^\sigma 0\} = \langle eb0\rangle = b^\sigma$ for all b. (Geometrically σ renames the points of AA' such that the line joining (0, 0) and (e, y) intersects AA' in (y).)

PROPOSITION 2. *Let R be a PTR with zero 0. Let e be any nonzero element of R. Then R is isotopic to a PTR with zero 0 and right unity e.*

Proof. Let $R=(S, \{\ \})$. Let ρ be the permutation on S defined by $\{xe0\} = x^\rho$. Define $[a^\rho bc] = \{abc\}$. Then $(S, [\])$ is a PTR with zero 0 and right unity e, since $[a^\rho e0] = \{ae0\} = a^\rho$ for all a. (Geometrically ρ renames the lines through A in such a way that the line containing (0, 0) and (e) contains all the points (x, x) with x in S.)

PROPOSITION 3. *A PTR with a zero is isotopic to a HTR.*

Proof. Let $(S, \langle\ \rangle)$ be a PTR with zero 0. Let $(S, \{\ \})$ be the isotope given in the proof of Proposition 1, with zero 0 and left unity e. Let $(S, [\])$ be the isotope of $(S, \{\ \})$ given in the proof of Proposition 2, with zero 0 and right unity e. If is sufficient to prove that e is also a left unity of $(S, [\])$. Since $e = \{ee0\} = e^\rho$, we have $[ex0] = [e^\rho x0] = \{ex0\} = x$ for all x in S.

THEOREM 18. *A ternary system is isotopic to a HTR if and only if it is an ITR.*

Proof. The theorem follows from Proposition 3 and the Corollary to Theorem 14.

The next theorem is motivated by the standard construction of introducing a unity into an algebra without divisors of zero. See, for example, Albert [1] where isotopy for division rings is discussed.

THEOREM 19. *Let $(S, \langle\ \rangle)$ be a PTR with a zero. Let g and h be any nonzero elements of S. Let z be any arbitrary element of S. Let $e=\langle ghz\rangle$. Define permutations ρ and σ on S by*

$$x^\rho = \langle xhz\rangle \qquad \text{and} \qquad y^\sigma = \langle gyz\rangle.$$

Then $(S, \{\ \})$ defined by $\langle abc\rangle = \{a^\rho b^\sigma c\}$ is a HTR with zero z and unity e.

Conversely, let $(S, \langle\ \rangle)$ be a PTR with a zero. Then any HTR isotopic to $(S, \langle\ \rangle)$ is isomorphic to a HTR constructed this way.

Proof. First note that, since $(S, \langle\ \rangle)$ is a PTR with a zero, ρ and σ are indeed permutations on S by Theorem 14. Since $(S, \{\ \})$ is an isotope of an ITR, it is at least an ITR. Suppose $(S, \langle\ \rangle)$ has zero 0. Then $0^\rho = z = 0^\sigma$ is a zero of $(S, \{\ \})$.

LATTICE POINTS AND POLYGONAL AREA

IVAN NIVEN, University of Oregon, and H. S. ZUCKERMAN, University of Washington

1. By a simple polygon is meant a polygon that is topologically equivalent to a circle. By lattice points in the plane we mean those points with integral coordinates. H. Steinhaus [1, p. 76] states the result that the area of a simple polygon all of whose vertices are lattice points is equal to the number of interior lattice points, plus half the number of lattice points on the boundary, minus one. Steinhaus offers so brief a sketch of the proof that it is not easy to formulate a complete argument. Because of this, and because this elegant theorem deserves to be known more widely, we offer here a full proof that we feel may also be of interest for its own sake.

2. Triangles.

THEOREM 1. *Let* (a, b) *and* (c, d) *be lattice points such that* (a, b), (c, d) *and the origin are not collinear. Let* T *denote the triangle with vertices* $(0, 0)$, (a, b), (c, d). *Then* T *has area* $\frac{1}{2}$ *if and only if*

(I) T *contains no lattice points other than its three vertices.*

Proof. The proof we give is not the shortest one possible but it is interesting

LATTICE POINTS AND POLYGONAL AREA

IVAN NIVEN, University of Oregon, and H. S. ZUCKERMAN, University of Washington

1. By a simple polygon is meant a polygon that is topologically equivalent to a circle. By lattice points in the plane we mean those points with integral coordinates. H. Steinhaus [1, p. 76] states the result that the area of a simple polygon all of whose vertices are lattice points is equal to the number of interior lattice points, plus half the number of lattice points on the boundary, minus one. Steinhaus offers so brief a sketch of the proof that it is not easy to formulate a complete argument. Because of this, and because this elegant theorem deserves to be known more widely, we offer here a full proof that we feel may also be of interest for its own sake.

2. Triangles.

THEOREM 1. *Let* (a, b) *and* (c, d) *be lattice points such that* (a, b), (c, d) *and the origin are not collinear. Let* T *denote the triangle with vertices* $(0, 0)$, (a, b), (c, d). *Then* T *has area* $\frac{1}{2}$ *if and only if*

(I) T *contains no lattice points other than its three vertices.*

Proof. The proof we give is not the shortest one possible but it is interesting

because of the various ideas that it combines. Let P be the parallelogram having vertices $(0, 0)$, (a, b), $(a+c, b+d)$, (c, d). First we prove that (I) is equivalent to:

(II) *P contains no lattice points other than its four vertices.*

It is obvious that (II) implies (I). To prove the converse suppose that P contains a lattice point (e, f) different from its vertices. If (e, f) is not in the triangle (a, b), $(a+c, b+d)$, (c, d) then it is in T and (I) is false. Therefore we can suppose that (e, f) is in that triangle. Translating P by the amount $-a-c$ in the x direction, $-b-d$ in the y direction, we see that $(e-a-c, f-b-d)$ is a lattice point in the triangle $(-c, -d)$, $(0, 0)$, $(-a, -b)$. Reflecting through the origin we find that $(-e+a+c, -f+b+d)$ is a lattice point in T, and hence (I) is false. Therefore (I) and (II) are equivalent.

Now the entire plane can be covered by replicas of P, each replica being P translated by the amount $ma+nc$ in the x direction, $mb+nd$ in the y direction, $m=0, \pm1, \pm2, \cdots, n=0, \pm1, \pm2, \cdots$. The edges of the parallelograms join to create a network N of lines, one set of lines parallel to the side $(0, 0)$ (a, b) of T, the other set parallel to $(0, 0)$ (c, d). Call the points at which these lines intersect, the vertices of N. The vertices of N are just the vertices of the replicas of P. They are all lattice points. If some lattice point is not a vertex of N it will lie in some replica of P and be distinct from the vertices of the replica of P. Translating, we would then have a lattice point in P, not a vertex of P. Thus we see that (II) is equivalent to:

(III) *All lattice points are vertices of N.*

We now get an algebraic statement equivalent to (III). It is clear that the vertices of N are just the points $(ma+nc, mb+nd)$. Therefore (III) is equivalent to

(IV) *For each pair of integers u, v there is a pair of integers m, n such that $am+cn=u$, $bm+dn=v$.*

But the solution of the equations in (IV) is

$$m = (du - cv)/\Delta, \qquad n = (av - bu)/\Delta, \qquad \Delta = ad - bc.$$

The fact that $(0, 0)$, (a, b), (c, d) are not collinear ensures that $\Delta \neq 0$. Obviously $\Delta = \pm 1$ implies (IV). Conversely (IV) implies that Δ divides both $du-cv$ and $av-bu$ for all pairs of integers u, v. In particular, taking first $u=1$, $v=0$, and then $u=0$, $v=1$, we have that (IV) implies that Δ divides each of d, b, c, a, hence Δ^2 divides $ad-bc=\Delta$. Since if Δ^2 divides Δ then $\Delta = \pm 1$, we see that (IV) is equivalent to $\Delta = \pm 1$.

Finally, it is a well-known, and easily proved, fact that the area of T is $\frac{1}{2}|\Delta|$. Therefore the theorem is proved.

3. Polygons. In order to extend the result of Section 2 we now define a certain set S. We let S consist of all simple polygons having all vertices at lattice points. Thus if U belongs to S then U is a polygon that consists of a single piece, has no holes, has all its vertices at lattice points, and is such that its boundary is a simple closed polygonal curve. If U and V belong to S and are such that the sets have in common a single connected part of the boundary of each, not just a single point, and no other points, then the union of the sets U and V forms a polygon of S. We denote this polygon by $U+V$. Notice that $U+V$ is not defined for all pairs U, V of S, but just for certain pairs.

Let $f(U)$ be a real valued function defined for all U of S. If $f(U)+f(V)=f(U+V)$ for all U, V for which $U+V$ is defined, then we say that $f(U)$ is an additive function.

THEOREM 2. *Let $I(U)$ denote the number of lattice points that are in the interior of U, not on the boundary. Let $B(U)$ denote the number of lattice points on the boundary of U. Let $f(U)=\alpha I(U)+\beta B(U)+\gamma$. Then $f(U)$ is additive if and only if $\beta=\alpha/2$, $\gamma=-\alpha$.*

Proof. Suppose that $f(U)$ is additive. Let U be the square (0, 0), (1, 0), (1, 1), (0, 1), V the square (1, 0), (2, 0), (2, 1), (1, 1), and W the rectangle (0, -1), (2, -1), (2, 0), (0, 0). Then both $U+V$ and $(U+V)+W$ are defined. Also $I(U)=0$, $B(U)=4$, $f(U)=4\beta+\gamma$. Similarly $f(V)=4\beta+\gamma$, $f(U+V)=6\beta+\gamma$, $f(W)=6\beta+\gamma$, $f((U+V)+W)=\alpha+8\beta+\gamma$. Therefore $8\beta+2\gamma=6\beta+\gamma$ and $12\beta+2\gamma=\alpha+8\beta+\gamma$, from which we find $\beta=\alpha/2$, $\gamma=-\alpha$.

Conversely, suppose that $\beta=\alpha/2$, $\gamma=-\alpha$ and that U and V are members of S such that $U+V$ is defined. Now U and V have in common just a part of the boundary of each. Let C denote the common boundary, and k the number of lattice points on C. Since C is more than just a point it contains at least two lattice points, the ends of C. Any lattice point on C other than the two endpoints is an interior point of $U+V$. Interior points of U and of V are interior points of $U+V$. We find $I(U+V)=I(U)+I(V)+k-2$. Similarly

$$B(U+V)=B(U)-k+B(V)-k+2=B(U)+B(V)-2k+2,$$

hence

$$\begin{aligned} f(U+V) &= \alpha I(U)+\beta B(U)+\alpha I(V)+\beta B(V)+\alpha(k-2)-2\beta(k-1)+\gamma \\ &= f(U)+f(V)+\alpha(k-2)-2\beta(k-1)-\gamma \\ &= f(U)+f(V) \end{aligned}$$

since $2\beta=\alpha$, $\gamma=-\alpha$. This completes the proof of the theorem.

The function $A(U)$, defined as the area of U, is also an additive function. Suppose that V is a triangle having no lattice points except its vertices. A translation by integral amounts will move V into a position with one vertex at the origin. The functions $A(U)$, $I(U)$ and $B(U)$ are invariant under such a transformation. Therefore the translated V is a T of section 2 and we have $A(V)=\frac{1}{2}$.

Also if V is any triangle in S having area $\frac{1}{2}$, then V contains no lattice points other than its three vertices.

THEOREM 3. *If W is any triangle in S then $A(W)=I(W)+\frac{1}{2}B(W)-1$.*

Proof. If $A(W)=\frac{1}{2}$ then we have just seen that $I(W)=0$, $B(W)=3$, and we see that the theorem holds in this case. For a general triangle W in S, let the vertices be (x_1, y_1), (x_2, y_2), (x_3, y_3), then

$$A(W) = \tfrac{1}{2}\left| (x_2 - x_1)(y_3 - y_1) - (y_2 - y_1)(x_3 - x_1) \right|$$

which is one half an integer. Therefore the theorem will follow by induction on the size of $A(W)$ if we show that any W can be expressed in the form $W=W_1+W_2$ or $W=W_1+W_2+W_3$ where the W_i are triangles of S having area less than $A(W)$. But this is easy. If there is a lattice point, other than a vertex, on a side of W, we break W into two triangles by means of a line from that point to the opposite vertex. If W contains an interior lattice point, we connect that point to the three vertices and break W into three triangles.

COROLLARY. *If C is a convex polygon in S then $A(C)=I(C)+\frac{1}{2}B(C)-1$.*

Proof. The polygon C can be broken into pieces, each a triangle of S. Then we use additivity and the preceding theorem.

THEOREM 4. *If P is any polygon in S then $A(P)=I(P)+\frac{1}{2}B(P)-1$.*

REMARK. The proof of the preceding corollary depends on the obvious fact that a convex polygon can be dissected into suitable triangles. Theorem 4 can be proved in the same way using the fact [2, p. 238] that any polygon can be dissected into triangles of the proper sort. However this result is not really needed. For the sake of completeness we give the following independent proof of Theorem 4.

Proof. We use induction on the number of vertices of P. If $n=3$ then P is a triangle and the theorem is true for P. Suppose that $n>3$ and that the theorem is true for all polygons with $n-1$ or fewer vertices. Let P have the vertices $A_1, A_2, \cdots, A_n$ and sides $A_1A_2, A_2A_3, \cdots, A_{n-1}A_n, A_nA_1$. Let P_0 be the smallest convex polygon containing P. Then P_0 is a convex polygon in S. The vertices of P_0 form a subset of $A_1, A_2, \cdots, A_n$. Some of the A_i may be interior points of P_0 and some may be boundary points but not vertices of P_0. If all the vertices of P are vertices of P_0, then P is convex and the theorem follows from the preceding corollary.

Now we can assume that some vertex of P is not a vertex of P_0, in fact that some vertex is actually an interior point of P_0. By possibly relabelling the subscripts of $A_1, A_2, \cdots, A_n$ in a cyclical fashion, we may presume that A_1 is an interior point of P_0. Now let $s\geqq 2$ be the smallest subscript such that A_s is on the boundary of P_0 and let $r\leqq n$ be the largest subscript such that A_r is on the boundary of P_0. Since P_0 has at least three vertices, we observe that at least

and these equations are inconsistent. Thus no constants c_i exist that make (4) correct, even just for tetrahedra.

The referee has drawn to our attention that Theorem 4 does generalize to 3-dimensional space in a form containing the Euler-Poincaré characteristic from algebraic topology; see Reeve [3].

AN EXPLICIT FORMULA FOR e^{At}

R. B. KIRCHNER, Carleton College

Let A be an $n \times n$ matrix of complex constants. In many textbooks on differential equations, e.g [1, 2, 3] the direct calculation of $e^{At} = \sum_{n=0}^{\infty} A^n t^n / n!$ is avoided except in the simplest cases. e^{At} is usually calculated by transforming A to Jordan canonical form. Although this procedure is theoretically straightforward, it is not easy to become convinced that one could actually carry out the computation for a given matrix A. E. J. Putzer has recently [see 4] given formulas for e^{At} in terms of A and solutions to an easily solved system of differential equations. We shall give an explicit formula for e^{At} in terms of A and the characteristic roots of A. The key idea is the Cayley-Hamilton theorem.

1. Notation and basic lemmas. Let $\lambda_1, \lambda_2, \cdots, \lambda_k$ denote the distinct characteristic roots of A, and put

$$p(\lambda) = \operatorname{Det}(\lambda I - A) = \prod_{i=1}^{k} (\lambda - \lambda_i)^{s_i},$$

$$p_j(\lambda) = \prod_{\substack{i=1 \\ i \neq j}}^{k} (\lambda - \lambda_i)^{s_i},$$

$$q(\lambda) = p_1(\lambda) + \cdots + p_k(\lambda),$$

$$f_n(x) = 1 + x + x^2/2! + \cdots + x^{n-1}/(n-1)!.$$

LEMMA 1. (*Cayley-Hamilton theorem*): $p(A) = 0$.

and these equations are inconsistent. Thus no constants c_i exist that make (4) correct, even just for tetrahedra.

The referee has drawn to our attention that Theorem 4 does generalize to 3-dimensional space in a form containing the Euler-Poincaré characteristic from algebraic topology; see Reeve [3].

AN EXPLICIT FORMULA FOR e^{At}

R. B. KIRCHNER, Carleton College

Let A be an $n \times n$ matrix of complex constants. In many textbooks on differential equations, e.g [1, 2, 3] the direct calculation of $e^{At} = \sum_{n=0}^{\infty} A^n t^n / n!$ is avoided except in the simplest cases. e^{At} is usually calculated by transforming A to Jordan canonical form. Although this procedure is theoretically straightforward, it is not easy to become convinced that one could actually carry out the computation for a given matrix A. E. J. Putzer has recently [see 4] given formulas for e^{At} in terms of A and solutions to an easily solved system of differential equations. We shall give an explicit formula for e^{At} in terms of A and the characteristic roots of A. The key idea is the Cayley-Hamilton theorem.

1. Notation and basic lemmas. Let $\lambda_1, \lambda_2, \cdots, \lambda_k$ denote the distinct characteristic roots of A, and put

$$p(\lambda) = \operatorname{Det}(\lambda I - A) = \prod_{i=1}^{k} (\lambda - \lambda_i)^{s_i},$$

$$p_j(\lambda) = \prod_{\substack{i=1 \\ i \neq j}}^{k} (\lambda - \lambda_i)^{s_i},$$

$$q(\lambda) = p_1(\lambda) + \cdots + p_k(\lambda),$$

$$f_n(x) = 1 + x + x^2/2! + \cdots + x^{n-1}/(n-1)!.$$

LEMMA 1. (*Cayley-Hamilton theorem*): $p(A) = 0$.

LEMMA 2. *If $r(\lambda)$ is a polynomial such that $r(\lambda_i)\neq 0$, $i=1, \cdots, k$, then $r(A)^{-1}$ exists and is expressible as a polynomial in A.*

Proof. Since $r(\lambda)$ and $p(\lambda)$ have no common factor, there are polynomials $s(\lambda)$ and $t(\lambda)$ such that $r(\lambda)s(\lambda)+p(\lambda)t(\lambda)=1$. The result follows by substituting A for λ in this identity and using Lemma 1.

LEMMA 3. *Let B be a square matrix. For each $j=1, 2, \cdots$ there is a matrix $g_j(B)$ such that $e^B=f_j(B)+B^j g_j(B)$.*

Proof. $g_j(B)=\sum_{n=j}^{\infty} B^{n-j}/n!$.

2. Statement of the formula. Since $q(\lambda_i)=\sum_{j=1}^{k} p_j(\lambda_i)=p_i(\lambda_i)\neq 0$, $i=1, \cdots, k$, $q(A)^{-1}$ exists by Lemma 2.

Choose $q_i(\lambda)$ so that $q_i(A)=q(A)^{-1}p_i(A)$, $i=1, \cdots, k$. The formula is

$$e^{At}=\sum_{i=1}^{k} q_i(A)f_{s_i}((A-I\lambda_i)t)e^{\lambda_i t}.$$

In applications, it is usually easier to solve for the $q_i(A)$ without first computing $q(A)^{-1}$. A technique for doing this will be illustrated in examples 2 and 3.

If it is convenient to solve for initial conditions separately, note that

$$q(A)e^{At}=\sum_{i=1}^{k} p_i(A)f_{s_i}((A-I\lambda_i)t)e^{\lambda_i t}$$

can be written at once, and its columns yield n linearly independent solutions to the system $\dot{x}=Ax$.

3. Proof of the formula. Let $B_i=A-I\lambda_i$. Then,

$$\begin{aligned} e^{At} &= q(A)^{-1}q(A)e^{At}=q(A)^{-1}\sum_{i=1}^{k} p_i(A)e^{B_i t+\lambda_i I t} \\ &= q(A)^{-1}\sum_{i=1}^{k} p_i(A)e^{B_i t}e^{\lambda_i I t} \\ &= q(A)^{-1}\sum_{i=1}^{k} [p_i(A)f_{s_i}(B_i t)+p_i(A)(B_i t)^{s_i}g_{s_i}(B_i t)]e^{\lambda_i t} \\ &= q(A)^{-1}\sum_{i=1}^{k} p_i(A)f_{s_i}(B_i t)e^{\lambda_i t}. \end{aligned}$$

We have used Lemma 1, Lemma 3, and the fact that $e^{M+N}=e^M e^N$ for commuting matrices M and N. It may be noted that only $p(A)=0$ is needed for the proof. The computation of e^{At} is therefore somewhat simplified if the minimal polynomial for A is known and has degree less than n.

A second proof may be made by simply checking that the formula solves the equation $\dot{Y}=AY$ with $Y(0)=I$.

4. A derivation of the formula. There are a number of ways of showing that the components of solutions to $\dot{x}=Ax$ satisfy the differential equation $p(D)y=0$. This follows, for example, from the operator identity $[\mathrm{adj}(DI-A)](DI-A)=p(D)I$ where $\mathrm{adj}(B)$ is the adjoint of B. Therefore, there are constant matrices B_{ij} such that

$$e^{At} = F(t) = \sum_{i=1}^{k}\sum_{j=1}^{s_i} B_{ij}[t^{j-1}/(j-1)!]e^{\lambda_i t}.$$

It is found that $\dot{F}(t)=AF(t)$ if

$$B_{ij}\lambda_i + B_{i,j+1} = AB_{ij}, \qquad 1 \leqq j < s_i, \qquad \lambda_i B_{i,s_i} = AB_{i,s_i}.$$

Rewriting these conditions as

$$B_{i,j+1} = (A-\lambda_i I)B_{ij}, \qquad 1 \leqq j < s_i, \qquad 0 = (A-\lambda_i I)B_{i,s_i},$$

we see that they are satisfied if $(A-\lambda_i I)^{s_i}B_{i,1}=0$. In view of the Cayley-Hamilton theorem, a candidate for $B_{i,1}$ is $p_i(A)$. Since $F(0)=B_{1,1}+\cdots+B_{k,1}$, it follows that $e^{At}=G(0)^{-1}G(t)$ where

$$G(t) = \sum_{i=1}^{k}\sum_{j=1}^{s_i} p_i(A)(A-\lambda_i I)^{j-1}[t^{j-1}/(j-1)!]e^{\lambda_i t}.$$

This is another way of writing the formula in Section 2.

5. Examples.

Example 1. $p(\lambda)=(\lambda-\lambda_1)^n$. In this case $q(A)=p_1(A)=I$, so $q_1(A)=I$. The formula yields simply,

$$e^{At} = [I + (A-\lambda_1 I)t + \cdots + (A-\lambda_1 I)^{n-1}t^{n-1}/(n-1)!]e^{\lambda_1 t}.$$

If it is known that $(A-\lambda_1 I)^m=0$ where $m<n$, then n can of course be replaced by m in the formula.

Example 2. $p(\lambda)=(\lambda-\lambda_1)(\lambda-\lambda_2)\cdots(\lambda-\lambda_n)$, and $\lambda_1, \lambda_2, \cdots, \lambda_n$ are distinct. In this case the formula is

$$e^{At} = \sum_{i=1}^{n} q_i(A)e^{\lambda_i t}.$$

The $q_i(A)$ can be evaluated explicitly as follows. Assume that $q_i(A)=\sum_{j=1}^{n} c_{ij}A^{j-1}$. The Cayley-Hamilton theorem implies that $Ap_i(A)=\lambda_i p_i(A)$, and hence that $A^j p_i(A)=\lambda^j p_i(A)$, $j\geqq 1$. Therefore,

$$p_i(A) = q_i(A)q(A) = \sum_{j=1}^{n}\sum_{m=1}^{n} c_{ij}A^{j-1}p_m(A)$$

$$= \sum_{m=1}^{n} p_m(A)\left[\sum_{j=1}^{n} c_{ij}\lambda_m^{j-1}\right].$$

For example, the coefficients of $q_1(A)$ and $q_2(A)$ in example 3 are the first and third rows of

$$\begin{bmatrix}1 & 0 & 1\\ 1 & 1 & 2\\ 1 & 2 & 4\end{bmatrix}^{-1} = \begin{bmatrix}0 & 2 & -1\\ -2 & 3 & -1\\ 1 & -2 & 1\end{bmatrix}.$$

The verification of this result proceeds by substituting $\sum_{j=1}^{n} c_{ij}A^{j-1}$ for $q_i(A)$ in $q_i(A)(p_1(A)+\cdots+p_k(A))=p_i(A)$, using the fact that

$$A^j p_i(A) = (\lambda_i I + B_i)^j p_i(A) = \sum_{h=0}^{s_i-1} \binom{j}{h} \lambda^{j-h} B_i^h p_i(A),$$

and equating coefficients of $B_i^h p_i(A)$, $0 \leqq h < s_i$, $1 \leqq i \leqq k$.

The fact that Λ is always nonsingular follows by noticing that if $f_{i\beta}(t) = t^{\beta-1}e^{\lambda_i t}/(\beta-1)!$, $1 \leqq \beta \leqq s_i$, $i=1, \cdots, k$, and $g_1(t), \cdots, g_n(t)$ are the solutions to $p(D)y=0$ such that $D^{\alpha-1}g_i(0)=\delta_{\alpha i}$, $1 \leqq \alpha \leqq n$, $1 \leqq i \leqq n$, then

$$(f_{11}(t), \cdots, f_{1,s_1}(t), \cdots, f_{k,s_k}(t)) = (g_1(t), \cdots, g_n(t))\Lambda.$$

Indeed, the $f_{i\beta}(t)$ satisfy $p(D)y=0$ and have initial conditions

$$\begin{aligned} D^{\alpha-1}f_{i\beta}(0) &= e^{\lambda_i t}(D+\lambda_i)^{\alpha-1}(t^{\beta-1}/(\beta-1)!)\big|_{t=0} \\ &= \binom{\alpha-1}{\beta-1}\lambda_i^{\alpha-\beta}. \end{aligned}$$

Since the $f_{i\beta}(t)$ are independent, Λ is nonsingular.

ANNIHILATORS OF SOME FUNCTION ALGEBRAS

JOHN LAMPERTI, Dartmouth College, and WALTER RUDIN, University of Wisconsin

Introduction. Let C be the space of all real continuous functions on the closed interval $[-1, 1]$. If $g \in C$, the *algebra generated by* g is the set A of all polynomials in g. More explicitly, $G \in A$ if and only if

$$G(x) = a_0 + a_1 g(x) + \cdots + a_n g^n(x) \qquad (-1 \leqq x \leqq 1), \tag{1}$$

For example, the coefficients of $q_1(A)$ and $q_2(A)$ in example 3 are the first and third rows of

$$\begin{bmatrix}1 & 0 & 1\\ 1 & 1 & 2\\ 1 & 2 & 4\end{bmatrix}^{-1} = \begin{bmatrix}0 & 2 & -1\\ -2 & 3 & -1\\ 1 & -2 & 1\end{bmatrix}.$$

The verification of this result proceeds by substituting $\sum_{j=1}^{n} c_{ij}A^{j-1}$ for $q_i(A)$ in $q_i(A)(p_1(A)+\cdots+p_k(A))=p_i(A)$, using the fact that

$$A^j p_i(A) = (\lambda_i I + B_i)^j p_i(A) = \sum_{h=0}^{s_i-1} \binom{j}{h} \lambda^{j-h} B_i^h p_i(A),$$

and equating coefficients of $B_i^h p_i(A)$, $0 \leqq h < s_i$, $1 \leqq i \leqq k$.

The fact that Λ is always nonsingular follows by noticing that if $f_{i\beta}(t) = t^{\beta-1}e^{\lambda_i t}/(\beta-1)!$, $1 \leqq \beta \leqq s_i$, $i=1, \cdots, k$, and $g_1(t), \cdots, g_n(t)$ are the solutions to $p(D)y=0$ such that $D^{\alpha-1}g_i(0)=\delta_{\alpha i}$, $1 \leqq \alpha \leqq n$, $1 \leqq i \leqq n$, then

$$(f_{11}(t), \cdots, f_{1,s_1}(t), \cdots, f_{k,s_k}(t)) = (g_1(t), \cdots, g_n(t))\Lambda.$$

Indeed, the $f_{i\beta}(t)$ satisfy $p(D)y=0$ and have initial conditions

$$\begin{aligned} D^{\alpha-1}f_{i\beta}(0) &= e^{\lambda_i t}(D+\lambda_i)^{\alpha-1}(t^{\beta-1}/(\beta-1)!)\big|_{t=0} \\ &= \binom{\alpha-1}{\beta-1}\lambda_i^{\alpha-\beta}. \end{aligned}$$

Since the $f_{i\beta}(t)$ are independent, Λ is nonsingular.

ANNIHILATORS OF SOME FUNCTION ALGEBRAS

JOHN LAMPERTI, Dartmouth College, and WALTER RUDIN, University of Wisconsin

Introduction. Let C be the space of all real continuous functions on the closed interval $[-1, 1]$. If $g \in C$, the *algebra generated by* g is the set A of all polynomials in g. More explicitly, $G \in A$ if and only if

$$G(x) = a_0 + a_1 g(x) + \cdots + a_n g^n(x) \qquad (-1 \leqq x \leqq 1), \tag{1}$$

where $a_0, \cdots, a_n$ are real constants.

We shall say that a function f *annihilates* A, or that $f \in A^{\perp}$, if f is integrable on $[-1, 1]$ and if it is true that

$$\int_{-1}^{1} G(x)f(x)dx = 0 \quad \text{for every } G \in A. \tag{2}$$

If $g \in C$ and g is one-to-one on $[-1, 1]$, the Stone-Weierstrass Theorem implies that every $\phi \in C$ can be uniformly approximated by members of A; therefore (2) can hold only if $f(x) = 0$ a.e. Moreover, any finite signed Borel measure μ which satisfies

$$\int_{-1}^{1} G(x)d\mu(x) = 0 \quad \text{for every } G \in A \tag{2'}$$

must vanish identically.

On the other hand, suppose that $g(a) = g(b)$ for some $a \neq b$. Then $G(a) = G(b)$ for every $G \in A$, and the same equality must hold for every function in the uniform closure of A. Thus A is not dense in C, and it is obvious that there exist nonzero Borel measures μ on $[-1, 1]$ such that $\int G d\mu = 0$ for all $G \in A$. But it is not immediately clear whether there always exist nontrivial *functions* f which annihilate A if the generator g of A is not one-to-one.

In Theorem 1 we find an affirmative answer for absolutely continuous g. Theorem 2 shows that the absolute continuity of g cannot be dropped from the hypotheses of Theorem 1. Finally, Theorem 3 describes a rather striking situation that can occur.

Before we turn to these results we mention one case in which it is apparent that $A^{\perp}$ contains many functions: *If g is even, then $A^{\perp}$ contains every odd $f \in L^1$.* Thus even when the function g is locally very irregular (and not absolutely continuous) there *may* be smooth nontrivial functions in $A^{\perp}$.

The following characteristic property of absolutely continuous functions will be used in Theorem 1: If ϕ is absolutely continuous on $[a, b]$, then $\phi'(x)$ exists a.e. on $[a, b]$, $\phi' \in L^1$, and

$$\phi(x) = \phi(a) + \int_a^x \phi'(t)dt \qquad (a \leqq x \leqq b). \tag{3}$$

THEOREM 1. *Suppose g is a real-valued absolutely continuous function on $[-1, 1]$ and g is not one-to-one. In this situation, the statement "If $g' \in X$ then $A^{\perp}$ contains a nontrivial $f \in X$" is true for $X = C^{\infty}$, for $X = C^n$, for $X = C$, and for $X = L^p (1 \leqq p \leqq \infty)$.*

Our notations are the customary ones: C^{∞} is the class of all infinitely differentiable functions, and for $n = 1, 2, \cdots, f \in C^n$ provided that $f^{(n)} \in C$. For $1 \leqq p \leqq \infty$ we understand $f \in L^p$ to mean that f is defined a.e., measurable, and that $\int_{-1}^{1} |f(x)|^p dx < \infty$ when $p < \infty$, or that ess. sup. $|f(x)| < \infty$ if $p = \infty$.

Proof. By assumption there exist points a and b such that $-1 \leqq a < b \leqq 1$ and $g(a) = g(b)$. We shall assume that g is not constant on $[a, b]$, for in the contrary case it is trivial to find an f with the required properties.

Suppose first that $1 \leqq p \leqq \infty$ and $g' \in L^p$. Define $f(x) = g'(x)$ on the interval $[a, b]$ and put $f(x) = 0$ elsewhere. It follows from (3) that f does not vanish a.e., and since g^{n+1} is absolutely continuous for $n = 0, 1, 2, \cdots$, (3) also implies that

$$\int_{-1}^{1} g^n(x) f(x)\,dx = \int_a^b g^n(x) g'(x)\,dx = \frac{1}{n+1}\left[g^{n+1}(b) - g^{n+1}(a)\right] = 0.$$

Thus $f \in A^{\perp}$, and the case $X = L^p$ is settled.

If X is C or C^n or C^∞ the preceding simple proof has to be modified so as to smooth f at the points a and b. We do this as follows: Since g is not constant on $[a, b]$ there exists a $\delta > 0$ and a closed interval $J \subset [a, b]$ such that g is not constant on J and such that $|g(x) - g(a)| > \delta$ for all $x \in J$. Choose $h \in C^\infty$ so that $h(u) = 0$ if $|u - g(a)| \leqq \delta$ and $h(u) > 0$ for all other real u. For instance, put

$$h(u) = \exp\left\{-\frac{1}{|u - g(a)| - \delta}\right\} \quad \text{if } |u - g(a)| > \delta.$$

Define

$$f(x) = \begin{cases} h(g(x))g'(x) & \text{if } a \leqq x \leqq b, \\ 0 & \text{otherwise.} \end{cases} \tag{4}$$

Since g is not constant on J and since $h(g(x)) > 0$ for $x \in J$, we see again that f is not identically 0. Since $h(g(x))$ vanishes in neighborhoods of a and of b, we see that $g' \in X$ now implies $f \in X$, if X is C or C^n or C^∞.

To show that $f \in A^{\perp}$, let n be a nonnegative integer and choose F so that $F'(u) = u^n h(u)$. Then

$$\int_{-1}^{1} g^n(x) f(x)\,dx = \int_a^b g^n(x) h(g(x)) g'(x)\,dx = F(g(b)) - F(g(a)) = 0,$$

since $g(a) = g(b)$. This completes the proof.

THEOREM 2. *Let ψ be a strictly increasing continuous function which maps $[0, 1]$ onto $[0, 1]$, and put*

$$g(x) = \begin{cases} -x & \text{if } -1 \leqq x \leqq 0, \\ \psi(x) & \text{if } 0 \leqq x \leqq 1. \end{cases} \tag{5}$$

In this situation the following statements hold:

(i) *If $\psi'(x) = 0$ on a dense subset of $[0, 1]$, then 0 is the only continuous function which annihilates A.*

(ii) *If $\psi'(x) = 0$ a.e. then $A^{\perp}$ contains only functions which vanish a.e.*

Proof. Suppose $h \in C$ and $h(-\psi(y)) = h(y)$ for $0 \leqq y \leqq 1$. Then h is in the uni-

(b) Theorem 2(ii) gives an example of an A which is not dense in C (since g is not one-to-one) but which *is* dense in L^p for all $p < \infty$, for otherwise $A^\perp$ would contain a nontrivial $f \in L^q \subset L^1$, where $1/p + 1/q = 1$. (Also, A is weak*-dense in L^∞.)

THEOREM 3. *There exists a $g \in C$ such that $A^\perp$ contains no $f \in C$ (other than 0) although $A^\perp$ does contain a nontrivial $f \in L^\infty$.*

Proof. Let g be of the form (5) once again. If ψ is absolutely continuous and $\psi' \in L^\infty$, then by Theorem 1 $A^\perp$ contains a nontrivial member of L^∞. If in addition $\psi' = 0$ on a dense subset of $[0, 1]$, then $A^\perp \cap C$ contains only the 0 function by Theorem 2(i). We complete the proof by constructing such a function ψ.

Enumerate the rationals in $[0, 1]$ as $r_1, r_2, r_3, \cdots$ and put

$$\lambda(x) = \sum_{n=1}^{\infty} \alpha_n [(x - r_n)^{1/3} + r_n^{1/3}], \qquad (0 \leqq x \leqq 1), \tag{11}$$

where $\alpha_1, \alpha_2, \alpha_3, \cdots$ are positive numbers which are chosen so as to make $\lambda(1) = 1$. Clearly λ is continuous and strictly increasing, and so its inverse, which is to be our function ψ, is well-defined and has the same properties. Since $\lambda'(x) = +\infty$ at each rational r_n, we have $\psi'(\lambda(r_n)) = 0$ and $\{\lambda(r_n)\}$ is a dense subset of $[0, 1]$. Hence the second condition above holds.

Next, (11) shows (by the mean value theorem, applied to each summand) that

$$|\lambda(x) - \lambda(y)| \geqq c|x - y|, \qquad (x, y \in [0, 1]), \tag{12}$$

where $3c = \sum \alpha_n$. This is the same as

$$|\psi(x) - \psi(y)| \leqq c^{-1}|x - y|, \qquad (x, y \in [0, 1]), \tag{13}$$

and (13) implies that ψ is absolutely continuous and that $\psi' \in L^\infty$. Thus ψ meets all of the requirements, and Theorem 3 is proved.

ON CONVERGENCE PROPERTIES OF SEQUENCES OF ANALYTIC FUNCTIONS

D. A. HEJHAL, University of Chicago

In the Classroom Notes section of the May 1965 issue of this MONTHLY, O. Shisha has an article entitled "On Sequences of Power Series with Restricted Coefficients" in which he provides elementary proofs for a number of interesting theorems. While doing work in several complex variables, the author obtained independently elementary proofs for several generalizations of Shisha's theorems. We present these now.

(b) Theorem 2(ii) gives an example of an A which is not dense in C (since g is not one-to-one) but which *is* dense in L^p for all $p < \infty$, for otherwise $A^\perp$ would contain a nontrivial $f \in L^q \subset L^1$, where $1/p + 1/q = 1$. (Also, A is weak*-dense in L^∞.)

THEOREM 3. *There exists a $g \in C$ such that $A^\perp$ contains no $f \in C$ (other than 0) although $A^\perp$ does contain a nontrivial $f \in L^\infty$.*

Proof. Let g be of the form (5) once again. If ψ is absolutely continuous and $\psi' \in L^\infty$, then by Theorem 1 $A^\perp$ contains a nontrivial member of L^∞. If in addition $\psi' = 0$ on a dense subset of $[0, 1]$, then $A^\perp \cap C$ contains only the 0 function by Theorem 2(i). We complete the proof by constructing such a function ψ.

Enumerate the rationals in $[0, 1]$ as $r_1, r_2, r_3, \cdots$ and put

$$\lambda(x) = \sum_{n=1}^{\infty} \alpha_n [(x - r_n)^{1/3} + r_n^{1/3}], \qquad (0 \leqq x \leqq 1), \tag{11}$$

where $\alpha_1, \alpha_2, \alpha_3, \cdots$ are positive numbers which are chosen so as to make $\lambda(1) = 1$. Clearly λ is continuous and strictly increasing, and so its inverse, which is to be our function ψ, is well-defined and has the same properties. Since $\lambda'(x) = +\infty$ at each rational r_n, we have $\psi'(\lambda(r_n)) = 0$ and $\{\lambda(r_n)\}$ is a dense subset of $[0, 1]$. Hence the second condition above holds.

Next, (11) shows (by the mean value theorem, applied to each summand) that

$$|\lambda(x) - \lambda(y)| \geqq c|x - y|, \qquad (x, y \in [0, 1]), \tag{12}$$

where $3c = \sum \alpha_n$. This is the same as

$$|\psi(x) - \psi(y)| \leqq c^{-1}|x - y|, \qquad (x, y \in [0, 1]), \tag{13}$$

and (13) implies that ψ is absolutely continuous and that $\psi' \in L^\infty$. Thus ψ meets all of the requirements, and Theorem 3 is proved.

ON CONVERGENCE PROPERTIES OF SEQUENCES OF ANALYTIC FUNCTIONS

D. A. HEJHAL, University of Chicago

In the Classroom Notes section of the May 1965 issue of this MONTHLY, O. Shisha has an article entitled "On Sequences of Power Series with Restricted Coefficients" in which he provides elementary proofs for a number of interesting theorems. While doing work in several complex variables, the author obtained independently elementary proofs for several generalizations of Shisha's theorems. We present these now.

THEOREM 1. *Define* $A_n(z, w) = \sum_{k,l\geq 0} a_{k,l,n} z^k w^l$ *for* $|z|<1 \times |w|<1$, *z and w complex. Suppose that* $a_{k,l,n} = \xi_{k,l} b_{k,l,n}$, *where* $|b_{k,l,n}| \leq M$ *and where* $\sum_{k,l} |\xi_{k,l}| |z|^k |w|^l$ *converges for* $|z|<1 \times |w|<1$. *Suppose that there exist sequences* $\{z_m\}$ *and* $\{w_j\}$ *in* $|z|<1$ *and* $|w|<1$ *(respectively) such that* $\{z_m\}$ *and* $\{w_j\}$ *converge to points in* $|z|<1$ *and* $|w|<1$, *and such that* $\lim_{n\to\infty} A_n(z_m, w_j)$ *exists for all m and j. Then,* $a_{k,l,n} \to a_{k,l}$ *for all k and l, and throughout* $|z|<1 \times |w|<1$ *we have*

$$\lim_{n\to\infty} A_n(z, w) = \sum_{k,l} a_{k,l} z^k w^l.$$

Furthermore, the convergence is uniform on compact subsets of $|z|<1 \times |w|<1$.

Remark. A corresponding theorem holds for any finite number of variables.

COROLLARY. *The theorem holds if the coefficients are uniformly bounded—as in the case of probability generating functions.*

Proof of the theorem. Since the set of all $b_{k,l,n}$ is bounded, and since the set of all (k, l) is countable, we can apply Cantor's diagonalization process to the $b_{k,l,n}$ to get a sequence $\{n_v\}$ such that $\lim_{n_v\to\infty} b_{k,l,n_v} = b_{k,l}$, say. Thus, $\lim_{n_v\to\infty} a_{k,l,n_v} = \xi_{k,l} b_{k,l} = a_{k,l}$. It is clear that the double series $\sum_{k,l} a_{k,l} z^k w^l$ converges in $|z|<1 \times |w|<1$. Next, we consider

$$\left| \sum_{k,l} [\xi_{k,l} b_{k,l,n_v} - \xi_{k,l} b_{k,l}] z^k w^l \right| \leq \sum_{k=0}^{A} \sum_{l=0}^{B} |\xi_{k,l}| |b_{k,l,n_v} - b_{k,l}| |z|^k |w|^l + \sum_{k=A+1}^{\infty} \sum_{l=0}^{B} + \sum_{k=A+1}^{\infty} \sum_{l=B+1}^{\infty} + \sum_{k=0}^{A} \sum_{l=B+1}^{\infty}$$

Hence,

$$\leq \sum_{k=0}^{A} \sum_{l=0}^{B} |\xi_{k,l}| |b_{k,l,n_v} - b_{k,l}| + 2M \left[\sum_{k=0}^{\infty} \sum_{l=0}^{\infty} |\xi_{k,l}| |z|^k |w|^l - \sum_{k=0}^{A} \sum_{l=0}^{B} |\xi_{k,l}| |z|^k |w|^l \right].$$

However, $\sum |\xi_{k,l}| |z|^k |w|^l$ is easily shown to be uniformly convergent in any $|z|<h_1<1 \times |w|<h_2<1$. We may choose the h_1 and h_2 so that $|z_m|<h_1$ and $|w_j|<h_2$ for all m and j. Choose A and B so large that

$$\left| \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} |\xi_{k,l}| |z_m|^k |w_j|^l - \sum_{k=0}^{A} \sum_{l=0}^{B} |\xi_{k,l}| |z_m|^k |w_j|^l \right| < \epsilon,$$

where $\epsilon > 0$ is arbitrarily chosen. Thus,

$$\left| A_{n_v}(z_m, w_j) - \sum_{k,l} \xi_{k,l} b_{k,l} z_m^k w_j^l \right| < 2M\epsilon + \sum_{k=0}^{A} \sum_{l=0}^{B} |\xi_{k,l}| \cdot |b_{k,l,n_v} - b_{k,l}|.$$

Proof. For one variable, define:

$$A_n(z) = 0,\ n \text{ odd}; \qquad A_n(z) = \sin\left(\operatorname{Log}\frac{1+z}{1-z}\right),\ n \text{ even } (|z| < 1).$$

We note that $\operatorname{Log} w = \ln|w| + i \arg w$, $-\pi < \arg w \leqq \pi$. Now, let $z_m = 1 - 2/(1+e^{m\pi})$, $m = 1, 2, 3, \cdots$. One may verify that $z_m \to 1$ from inside $|z| = 1$ and that $A_n(z_m) = 0$. If, setting

$$\sin\left(\operatorname{Log}\frac{1+z}{1-z}\right) = \sum_{k=0}^{\infty} c_k z^k, \qquad |z| < 1,$$

we let $M = 1$ and $\xi_k = c_k$, then the hypotheses of Theorem 1 are satisfied. But, $\lim_{n\to\infty} A_n(z)$ does not in general exist. To generalize to n-variables, regard the above as functions of n variables: $(z, z_2, z_3, \cdots, z_n)$.

This paper was written while the author was a student at Lane Technical High School in Chicago.

CORRECTION FOR "A CHARACTERIZATION OF FINITE FIELDS"

BROTHER JOSEPH HEISLER, C.S.C., St. Edward's University, Austin, Texas

W. M. Lambert, Jr. has pointed out that the argument in the proof of Theorem 2 of my paper (this MONTHLY, 74 (1967) 537–538) is not complete. Namely, in the third full paragraph on page 538, it is possible that $u = v$ and hence there does not exist a function f with $f(u) = v$ and $f(v)$ arbitrary. The argument is valid for rings containing two distinct proper divisors of zero. If otherwise ring R has only order two nilpotent proper divisors of zero, say $uu = 0$, and contains an element v, $v \neq 0$ and $v \neq u$, then consider the mapping f: $R \to R$ with $f(0) = 0$ and $f(x) = v$ otherwise. If f is left represented by $\bar{f}(x) = a_n x^n + \cdots + a_1 x + a_0$ then

$$f(0) = 0 = a_0$$

and $f(u) = a_1 u = v$ implies $a_1 u^2 = vu$.

On the one hand, $a_1 u^2 = 0$ but $vu \neq 0$, a contradiction, so that R cannot have only order two nilpotent proper divisors of zero.

Proof. For one variable, define:

$$A_n(z) = 0,\ n \text{ odd}; \qquad A_n(z) = \sin\left(\operatorname{Log}\frac{1+z}{1-z}\right),\ n \text{ even } (|z| < 1).$$

We note that $\operatorname{Log} w = \ln|w| + i \arg w$, $-\pi < \arg w \leqq \pi$. Now, let $z_m = 1 - 2/(1+e^{m\pi})$, $m = 1, 2, 3, \cdots$. One may verify that $z_m \to 1$ from inside $|z| = 1$ and that $A_n(z_m) = 0$. If, setting

$$\sin\left(\operatorname{Log}\frac{1+z}{1-z}\right) = \sum_{k=0}^{\infty} c_k z^k, \qquad |z| < 1,$$

we let $M = 1$ and $\xi_k = c_k$, then the hypotheses of Theorem 1 are satisfied. But, $\lim_{n\to\infty} A_n(z)$ does not in general exist. To generalize to n-variables, regard the above as functions of n variables: $(z, z_2, z_3, \cdots, z_n)$.

This paper was written while the author was a student at Lane Technical High School in Chicago.

CORRECTION FOR "A CHARACTERIZATION OF FINITE FIELDS"

BROTHER JOSEPH HEISLER, C.S.C., St. Edward's University, Austin, Texas

W. M. Lambert, Jr. has pointed out that the argument in the proof of Theorem 2 of my paper (this MONTHLY, 74 (1967) 537–538) is not complete. Namely, in the third full paragraph on page 538, it is possible that $u = v$ and hence there does not exist a function f with $f(u) = v$ and $f(v)$ arbitrary. The argument is valid for rings containing two distinct proper divisors of zero. If otherwise ring R has only order two nilpotent proper divisors of zero, say $uu = 0$, and contains an element v, $v \neq 0$ and $v \neq u$, then consider the mapping f: $R \to R$ with $f(0) = 0$ and $f(x) = v$ otherwise. If f is left represented by $\bar{f}(x) = a_n x^n + \cdots + a_1 x + a_0$ then

$$f(0) = 0 = a_0$$

and $f(u) = a_1 u = v$ implies $a_1 u^2 = vu$.

On the one hand, $a_1 u^2 = 0$ but $vu \neq 0$, a contradiction, so that R cannot have only order two nilpotent proper divisors of zero.

In an unbounded space the situation is quite different, since the diameters of $g^n(X)$ may not tend to zero. (For example, on a Banach space $g=\frac{1}{2}I$ is contractive but $g^n(X)=X$ for all n.) In this case, for any z, let $Y(z)=\overline{B_z}(d(z, g(z))/(1-k))$, the closed ball with center z and radius $d(z, g(z))/(1-k)$. Since $g(Y(z)) \subset Y(z)$ and diam $Y(z)=\Delta \leqq 2d(z, g(z))/(1-k)$, we can apply the results of the preceding discussion to the restriction of g to $Y(z)$. After proving that the fixpoint of g, and thus of f is unique on X, we conclude that part (i) of the Theorem is proven, while part (ii) is now modified to: *If* $x_n \in f^{pn}(Y(z))$ *then* $\{x_n\} \to \xi$. Since $f^{pn+s}(Y(z))$ is not necessarily included in $g^n(Y(z))$, we can only conclude in place of (iii'): *If* $x_n \in f^{pn}(Y(z))$ *then* $d(\xi, x_n) \leqq \Delta k^n \leqq 2k^n d(z, f^p(z))/(1-k)$.

ON QUADRILATERAL SPACES

DONALD WATSON, RAAF Academy, Point Cook, Australia

D. M. Smiley and M. F. Smiley [1] have defined a quadrilateral space as a real normed linear space for which the quadrilateral inequality

$$|x| + |y| + |z| + |x+y+z| \geqq |x+y| + |y+z| + |z+x|$$

holds. They showed that in a quadrilateral space both the triangle and polygonal inequalities are true; that is,

$$|x| + |y| - |x+y| \geqq 0 \tag{1}$$

and

$$C(n-2, k-1)S_1 + C(n-2, k-2)S_n \geqq S_k \qquad (1 < k < n), \tag{2}$$

where

$$S_k = \sum (|x_{i_1} + x_{i_2} + \cdots + x_{i_k}| : 1 \leqq i_1 < i_2 < \cdots < i_k \leqq n)$$

and $\{x_1, x_2, \cdots, x_n\}$ is a set N of any n vectors in the space.

The purpose of this note is to interpret (1) and (2) in terms of a sequence of means associated with the set N, and to extend (2).

We construct a mean, μ_k, in the following way. Select k vectors from N and form the norm of their arithmetic mean. The number of such selections, and norms, is $C(n, k)$; and μ_k is the arithmetic mean of these norms. That is,

$$\mu_k = \{kC(n, k)\}^{-1} S_k \qquad (k = 1, \cdots, n).$$

The means have a simple geometrical interpretation when N comprises three vectors proceeding from an origin O. The ends of the vectors and the origin are the vertices of a tetrahedron: μ_1 is the mean length of the edges through O;

In an unbounded space the situation is quite different, since the diameters of $g^n(X)$ may not tend to zero. (For example, on a Banach space $g=\frac{1}{2}I$ is contractive but $g^n(X)=X$ for all n.) In this case, for any z, let $Y(z)=\overline{B_z}(d(z, g(z))/(1-k))$, the closed ball with center z and radius $d(z, g(z))/(1-k)$. $$\mu_k = \{kC(n, k)\}^{-1} S_k \qquad (k = 1, \cdots, n).$$

The means have a simple geometrical interpretation when N comprises three vectors proceeding from an origin O. The ends of the vectors and the origin are the vertices of a tetrahedron: μ_1 is the mean length of the edges through O;

I close with an observation concerning equality in (5). The necessary and sufficient conditions on a set N for equality to hold in (2) have been given in [1]. Equality will clearly hold in (5) if these conditions are satisfied by every subset M comprising m vectors of N, and the possibility of equality in (5) under other conditions is shown by an example supplied—along with other helpful comments—by a referee. If $n=5$, $x_1=1$, $x_2=2$, $x_3=3$, $x_4=4$, $x_5=-9$ there is equality in (5) for $m=4$, but not in (2).

ON AN nth ORDER DIFFERENTIAL EQUATION

M. S. KLAMKIN, Ford Scientific Laboratory, Dearborn, Michigan

The differential equations

$$[D^3 + 3axD^2 + 3a^2x^2D + a^3x^3]y = 0, \tag{1}$$

$$[D^4 + 4axD^3 + 6a^2x^2D^2 + 4a^3x^3D + a^4x^4]y = 0, \tag{2}$$

have been solved by Craig [1] by transforming them into linear equations with constant coefficients. In this note, we effect the reduction of the corresponding nth order equation, i.e.,

$$\left[D^n - \binom{n}{1}xD^{n-1} + \binom{n}{2}x^2D^{n-2} - \cdots (-1)^n\binom{n}{n}x^n\right] = 0. \tag{3}$$

(By letting $x=kx'$, we can obtain the forms (1) and (2).)

The reduction follows immediately from the identity

$$(i\sqrt{2})^n \sum_{s=0}^{n} (-1)^s \binom{n}{s} x^s D^{n-s}y \equiv e^{x^2/2}H_n(iD/\sqrt{2})ye^{-x^2/2}, \tag{4}$$

where $H_n(x)$ is the Hermite polynomial

$$H_n(x) = \sum_{r=0}^{[n/2]} \frac{(-1)^r(n!)(2x)^{n-2r}}{(n-2r)!\,r!}.$$

To establish the identity, note that

$$e^{t^2}H_n\left(\frac{i}{2}\frac{d}{dt}\right)ye^{-t^2} = e^{t^2}\sum_{r=0}^{[n/2]}\frac{(-1)^r n!}{(n-2r)!\,r!}\left(i\frac{d}{dt}\right)^{n-2r}ye^{-t^2}$$

$$= \sum_{r=0}^{[n/2]}\frac{i^n n!}{(n-2r)!\,r!}\sum_{s=0}^{n-2r}\binom{n-2r}{s}(D^s y)e^{t^2}D^{n-2r-s}e^{-t^2}.$$

Since $H_n(t) = (-1)^n e^{t^2} D^n e^{-t^2}$, we have, after interchanging the order of summation, that

$$e^{t^2} H_n\left(\frac{i}{2}\frac{d}{dt}\right) y e^{-t^2} = \sum_{s=0}^{n} \sum_{r=0}^{[s/2]} \frac{i^n (-1)^{s-2r} n!}{(n-2r)!\, r!} \binom{n-2r}{n-s} H_{s-2r}(t) D^{n-s} y.$$

Now letting $t = x/\sqrt{2}$ and using the expansion [2]

$$(2x)^s = \sum_{r=0}^{[s/2]} \frac{s! H_{s-2r}(x)}{(s-2r)!\, r!},$$

we finally obtain the identity (4).

A GENERALIZED ARITHMETIC COMPOSITION

MARGARET D. GESSLEY, Temple, Texas

DEFINITION. *Let f and g be two arithmetic functions. Then*

$$(f \times g)(n) = \sum_{ab=n} f(a) g(b) K(a, b),$$

where the kernel $K(a, b)$ is a nonvanishing function of two variables satisfying

(1) $K(a, b)K(ab, c) = K(b, c)K(a, bc)$

(2) $K(a, b)$ *is multiplicative in both variables, i.e., if* $(ac, bd) = 1$, *then* $K(ab, cd) = K(a, c)K(b, d)$.

This composition is associative, and has the function $E_0(n) = [1/n]$ as an identity. To establish commutativity, it is first necessary to prove the following

THEOREM 1. *For any two positive integers a and b, $K(a, b) = K(b, a)$.*

Proof. We shall use induction.

By condition (1), $K(a, b)K(ab, c) = K(b, c)K(a, bc)$. Let $a = 1$, then $K(1, b)K(b, c) = K(b, c)K(1, bc)$ which implies $K(1, b) = K(1, bc)$ for all c and b. It certainly holds for $b = 1$, which implies $K(1, 1) = K(1, c)$ for all c. Therefore $K(1, c)$ is constant.

Let $b = 1$, then $K(a, 1)K(a, c) = K(1, c)K(a, c)$ which implies $K(a, 1) = K(1, c)$ for all a and c. Therefore $K(a, 1)$ is constant. Since K is multiplicative in both variables, if $(ac, bd) = 1$, $K(ab, cd) = K(a, c)K(b, d)$. Take $a = b = 1$, $(c, d) = 1$. Then $(ac, bd) = 1$, so that $K(1, cd) = K(1, c)K(1, d)$. But $K(1, x)$ is constant, say N. Therefore $N = N^2$. Since $K(a, b) \neq 0$, $N = 1$ so $K(1, a) = 1 = K(b, 1)$ for all a, b.

We next shall show that $K(p^\alpha, p^\beta) = K(p^\beta, p^\alpha)$, where p is a prime, $\alpha, \beta > 0$.

By condition (1) taking $a = p^x$, $b = p^y$, $c = p^z$, we have

$$K(p^x, p^y)K(p^{x+y}, p^z) = K(p^y, p^z)K(p^x, p^{y+z}). \tag{3}$$

With $x=y=z=1$ in (3) we get $K(p^2, p)=K(p, p^2)$. Assume $K(p^\gamma, p)=K(p, p^\gamma)$, and in (3) take $x=z=1$, $y=\gamma$; we get $K(p^{\gamma+1}, p)=K(p, p^{\gamma+1})$. Hence $K(p^\alpha, p^\beta)=K(p^\beta, p^\alpha)$ is true for all $\beta \geqq 0$ if $\alpha=1$. Now assume this statement is also true for all β if $\alpha<t$, $(t \geqq 1)$. Hence for $\alpha=t$, we have the result immediately if $\beta<\alpha$ by the induction hypothesis. Also there is nothing to prove if $\alpha=\beta$.

Taking $x=z=t$ and $y=1$ in (3) we get $K(p^t, p)K(p^{t+1}, p^t)=K(p^t, p^{t+1}) \cdot K(p, p^t)$, which implies $K(p^{t+1}, p^t)=K(p^t, p^{t+1})$. Assume $K(p^t, p^\beta)=K(p^\beta, p^t)$ for $\beta=t, \cdots, \delta+t(\delta \geqq 0)$ and in (3) take $x=z=t$ and $y=\delta+1$ to get

$$K(p^t, p^{\delta+1})K(p^{t+\delta+1}, p^t) = K(p^t, p^{t+\delta+1})K(p^{\delta+1}, p^t). \tag{4}$$

Now if $\delta+1 \leqq t$, we have already proved that $K(p^t, p^{\delta+1})=K(p^{\delta+1}, p^t)$, so from (4) the induction is complete. If $t<\delta+1$, we have $\delta+1 \leqq t+\delta$, so the induction hypothesis applies and we again cancel in (4) to get $K(p^{t+\delta+1}, p^t)=K(p^t, p^{t+\delta+1})$. This completes the proof that $K(p^\alpha, p^\beta)=K(p^\beta, p^\alpha)$ for all α, β.

By induction on the number of primes in a and b, the proof is complete.

Further, by generalizations of the proofs for the Dirichlet composition, it can be shown that the composition of two multiplicative functions is multiplicative and the inverses with respect to $E_0(n)$ of multiplicative functions exist and are multiplicative.

Acknowledgment. The author wishes to thank Dr. A. A. Gioia for his assistance in the preparation of this paper.

THE EQUI-PAPPIAN PROPERTY

J. GARFUNKEL, Forest Hills High School and S. GARFUNKEL, Cornell University

An article on concentric polygons appeared in this MONTHLY [3]. We have arrived at some additional results which we believe to be of sufficient interest to be added to the literature of this subject.

Our investigation consists of examining a certain property of three directed line segments, a property which we call "equi-Pappian". In order to give a rigorous definition of this property we first introduce the notion of a *directed polygon.*

Suppose that we are given a polygon with consecutive vertices A_1, A_2, A_3, $\cdots$, A_n. Such a polygon is usually described by listing the vertices in order, starting with A_1; thus, $A_1A_2A_3 \cdots A_n$ describes this polygon. At the same time, $A_1A_nA_{n-1} \cdots A_2$ describes this polygon equally well, unless we wish to assign a consistent sense of orientation to the sides of the polygon. Such a polygon whose sides are directed line segments yielding such a consistent sense of orientation is

$$K(p^x, p^y)K(p^{x+y}, p^z) = K(p^y, p^z)K(p^x, p^{y+z}). \tag{3}$$

With $x=y=z=1$ in (3) we get $K(p^2, p)=K(p, p^2)$. Assume $K(p^\gamma, p)=K(p, p^\gamma)$, and in (3) take $x=z=1$, $y=\gamma$; we get $K(p^{\gamma+1}, p)=K(p, p^{\gamma+1})$. Hence $K(p^\alpha, p^\beta)=K(p^\beta, p^\alpha)$ is true for all $\beta \geqq 0$ if $\alpha=1$. Now assume this statement is also true for all β if $\alpha<t$, $(t \geqq 1)$. Hence for $\alpha=t$, we have the result immediately if $\beta<\alpha$ by the induction hypothesis. Also there is nothing to prove if $\alpha=\beta$.

Taking $x=z=t$ and $y=1$ in (3) we get $K(p^t, p)K(p^{t+1}, p^t)=K(p^t, p^{t+1}) \cdot K(p, p^t)$, which implies $K(p^{t+1}, p^t)=K(p^t, p^{t+1})$. Assume $K(p^t, p^\beta)=K(p^\beta, p^t)$ for $\beta=t, \cdots, \delta+t(\delta \geqq 0)$ and in (3) take $x=z=t$ and $y=\delta+1$ to get

$$K(p^t, p^{\delta+1})K(p^{t+\delta+1}, p^t) = K(p^t, p^{t+\delta+1})K(p^{\delta+1}, p^t). \tag{4}$$

Now if $\delta+1 \leqq t$, we have already proved that $K(p^t, p^{\delta+1})=K(p^{\delta+1}, p^t)$, so from (4) the induction is complete. If $t<\delta+1$, we have $\delta+1 \leqq t+\delta$, so the induction hypothesis applies and we again cancel in (4) to get $K(p^{t+\delta+1}, p^t)=K(p^t, p^{t+\delta+1})$. This completes the proof that $K(p^\alpha, p^\beta)=K(p^\beta, p^\alpha)$ for all α, β.

By induction on the number of primes in a and b, the proof is complete.

Further, by generalizations of the proofs for the Dirichlet composition, it can be shown that the composition of two multiplicative functions is multiplicative and the inverses with respect to $E_0(n)$ of multiplicative functions exist and are multiplicative.

Acknowledgment. The author wishes to thank Dr. A. A. Gioia for his assistance in the preparation of this paper.

THE EQUI-PAPPIAN PROPERTY

J. GARFUNKEL, Forest Hills High School and S. GARFUNKEL, Cornell University

An article on concentric polygons appeared in this MONTHLY [3]. We have arrived at some additional results which we believe to be of sufficient interest to be added to the literature of this subject.

Our investigation consists of examining a certain property of three directed line segments, a property which we call "equi-Pappian". In order to give a rigorous definition of this property we first introduce the notion of a *directed polygon.*

Suppose that we are given a polygon with consecutive vertices A_1, A_2, A_3, $\cdots$, A_n. Such a polygon is usually described by listing the vertices in order, starting with A_1; thus, $A_1A_2A_3 \cdots A_n$ describes this polygon. At the same time, $A_1A_nA_{n-1} \cdots A_2$ describes this polygon equally well, unless we wish to assign a consistent sense of orientation to the sides of the polygon. Such a polygon whose sides are directed line segments yielding such a consistent sense of orientation is

called a *directed polygon*, and is denoted by $A_1A_2A_3 \cdots A_n$ or by $A_1A_nA_{n-1} \cdots A_2$ (depending on the specific orientation). Thus, for example, any three noncollinear points X, Y, Z are the vertices of two directed triangles XYZ and XZY, [4].

DEFINITION. *Let* $\overrightarrow{A_1B_1}$, $\overrightarrow{A_2B_2}$, $\overrightarrow{A_3B_3}$ *be three directed line segments. On each of these erect directed equilateral triangles* $A_iB_iC_i$ $(i=1, 2, 3)$ *so that all three triangles have the same sense of orientation, then the segments* $\overrightarrow{A_iB_i}$ $(i=1, 2, 3)$ *are said to be equi-Pappian if and only if triangle* $C_1C_2C_3$ *is equilateral.*

Thus, according to the above definition, the three segments consisting of the middle third of each of the sides of any directed scalene triangle [2] are equi-Pappian. We will now prove a few theorems involving this property. The method used will be that of considering vectors in the complex plane. We will make extensive use of the vectors ω, ω^2 to describe rotations of 120° and 240°, employing the fact that $\omega^3=1$, and $1+\omega+\omega^2=0$.

THEOREM 1. *If* ABC *and* $A'B'C'$ *are two directed equilateral triangles, then the joins of corresponding vertices* $\overrightarrow{AA'}$, $\overrightarrow{BB'}$, $\overrightarrow{CC'}$ *are equi-Pappian.*

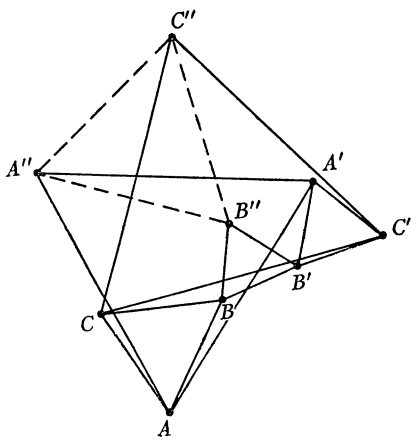

FIG. 1

Proof. Let $\overrightarrow{CB}=p$, $\overrightarrow{CC'}=q$, $\overrightarrow{B'C'}=r$. Then $\overrightarrow{CA}=-p\omega$, $\overrightarrow{AB}=-p\omega^2$. We have

$$\overrightarrow{CB'} = q - r, \quad \overrightarrow{BB'} = q - (r + p), \quad \overrightarrow{B'B''} = q\omega - (r + p)\omega,$$

$$\overrightarrow{B''B} = q\omega^2 - (r + p)\omega^2, \quad \overrightarrow{BA'} = q - (r + p) - r\omega^2,$$

$$\overrightarrow{AA'} = - p\omega^2 + q - (r + p) - r\omega^2 = - (p + r)\omega^2 + q - (p + r),$$

$$\overrightarrow{A'A''} = - (p + r) + q\omega - (p + r)\omega, \quad \overrightarrow{A''A} = - (p + r)\omega + q\omega^2 - (p + r)\omega^2.$$

Hence

$$\overrightarrow{B''C''} = \overrightarrow{B''B'} + \overrightarrow{B'C'} + \overrightarrow{C'C''} = p\omega - r\omega^2,$$

$$\overrightarrow{C''A''} = \overrightarrow{C''C'} + \overrightarrow{C'C} + \overrightarrow{CA} + \overrightarrow{AA''} = -q\omega - q - p\omega + (p+r)\omega - q\omega^2 + (p+r)\omega^2 = p\omega^2 - r = (\overrightarrow{B''C''})\omega,$$

which proves the theorem.

COROLLARY. *Three directed line segments emanating from a point are equi-Pappian if and only if the joins of their endpoints form an equilateral triangle.*

We omit the proof of this corollary.

THEOREM 2. *Quadrilateral $ABCD$ is a parallelogram if and only if $\overrightarrow{AD}$, $\overrightarrow{AC}$, $\overrightarrow{BC}$ are equi-Pappian.*

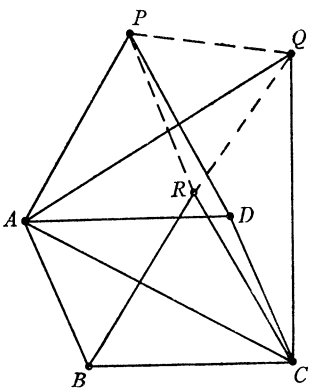

FIG. 2

Proof. Let $\overrightarrow{AB}=p$, $\overrightarrow{BC}=q$, and $\overrightarrow{AD}=r$. Let P, Q, and R be points such that the directed triangles ADP, ACQ, and BCR with the same orientation are equilateral. Assume that triangle PQR is equilateral. $\overrightarrow{RQ}=\overrightarrow{RC}+\overrightarrow{CQ}=-q\omega+(p+q)\omega=p\omega$.

Now, $\overrightarrow{QP}=\overrightarrow{QA}+\overrightarrow{AP}=(p+q)\omega^2-r\omega^2$. $(\overrightarrow{RQ})\omega=\overrightarrow{QP}$ by hypothesis, i.e., $p\omega^2=p\omega^2+q\omega^2-r\omega^2$, or $(q-r)\omega^2=0$. Hence $q=r$ and $ABCD$ is a parallelogram. Assume $ABCD$ is a parallelogram, i.e. $\overrightarrow{AD}=q$. As before, $\overrightarrow{RQ}=p\omega$. $\overrightarrow{QP}=(p+q)\omega^2-q\omega^2=p\omega^2$, therefore $(\overrightarrow{RQ})\omega=\overrightarrow{QP}$ and triangle PQR is equilateral.

In 1956 Beth and Tarski [1] proved that in the plane, all of Euclidean geometry cannot be formalized solely on the basis of the notion of equilateral triangles. This theorem shows that the concept of parallelism is one notion that can be so formalized.

THEOREM 3. *If three consecutive sides $\overrightarrow{AB}$, $\overrightarrow{BC}$, $\overrightarrow{CD}$ of a directed quadrilateral*

ABCD are equi-Pappian, then $\overrightarrow{AD}, \overrightarrow{AC}, \overrightarrow{BD}$ *(the fourth side and the two diagonals) are equi-Pappian.*

Proof. In Figure 3, let $\overrightarrow{AB}=q$, $\overrightarrow{BC}=r$, $\overrightarrow{CD}=p$ and proceed as before to show that $(\overrightarrow{Q'P'})\omega=\overrightarrow{P'R'}$

THEOREM 4. *If the set of three alternate sides of a directed hexagon (not necessarily convex) is equi-Pappian, then the remaining three sides are equi-Pappian.*

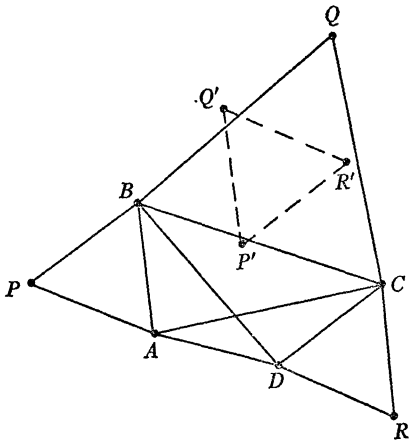

FIG. 3

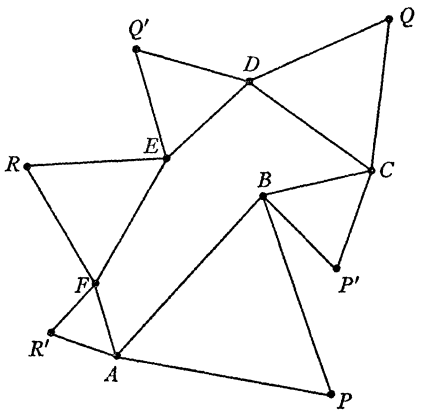

FIG. 4

Proof. In Figure 4, let $\overrightarrow{AB}=p$, $\overrightarrow{BC}=q$, $\overrightarrow{CD}=r$, $\overrightarrow{DE}=s$, $\overrightarrow{EF}=t$, $\overrightarrow{FA}=u$, and proceed exactly along the same lines as in previous theorems to show that $(\overrightarrow{Q'R'})=(P'Q')\omega$.

The following corollary is interesting as it yields an easy proof of Theorem 7 of [2].

COROLLARY. *If the set of alternate segments* $\overrightarrow{AN}, \overrightarrow{BL}, \overrightarrow{CM}$ *of a directed triangle ABC is equi-Pappian, then the set of segments* $\overrightarrow{NB}, \overrightarrow{LC}, \overrightarrow{MA}$ *is also equi-Pappian.*

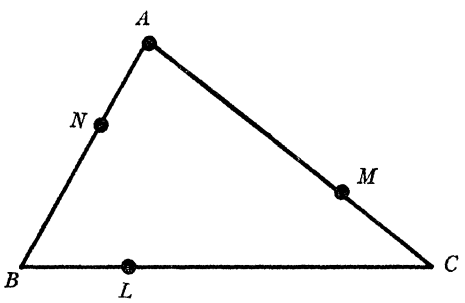

FIG. 4.1

Proof. Consider triangle ABC with L, M, N, points on the sides as directed hexagon $ANBLCM$ with straight angles at L, M, N and the corollary follows from the previous theorem (Figure 4.1).

No attempt has been made to exhaust the results that can be obtained by the investigation of this so called equi-Pappian property of three directed line segments. We feel sure that many additional results involving this property can be found.

PRODUCT OF ULTRASPHERICAL POLYNOMIALS

RICHARD ASKEY, The University of Wisconsin, Madison

As is well known $\cos nx \cos mx = \frac{1}{2}[\cos(n+m)x + \cos(n-m)x]$ and $\sin nx \cos mx = \frac{1}{2}[\sin(n+m)x + \sin(n-m)x]$. The first of these formulas has been generalized to ultraspherical polynomials and we give here a generalization of the second one.

Let $P_n^\lambda(x)$ be defined by $(1-2rx+r^2)^{-\lambda} = \sum_{n=0}^\infty P_n^\lambda(x) r^n$, $\lambda > 0$. Then Dougall and Hsü [2] have obtained the formula

$$P_n^\lambda(x) P_m^\lambda(x) = \sum_{k=0}^{\min(n,m)} \frac{\alpha_{m-k}^\lambda \alpha_{n-k}^\lambda}{\alpha_{n+m-k}^\lambda} \frac{\alpha_k^\lambda h_{n+m-k}^\lambda}{h_{n+m-2k}^\lambda} P_{n+m-2k}^\lambda(x). \tag{1}$$

Here

$$\alpha_n^\lambda = \binom{n+\lambda-1}{n} \quad \text{and} \quad h_n^\lambda = \frac{2^{1-2\lambda}\pi}{[\Gamma(\lambda)]^2} \frac{\Gamma(n+2\lambda)}{(n+\lambda)n!}.$$

We define $\alpha_n^\lambda = 0$ if n is a negative integer. Observe that the coefficient of $P_r^\lambda(x)$ is positive in (1).

Since $\lim_{\lambda \to 0^+} [P_n^\lambda(\cos\theta)]/P_n^\lambda(1) = \cos n\theta$ it is easy to see that (1) generalizes the above formula for $\cos nx \cos mx$. In trying to generalize the second recall that $P_n^1(\cos\theta) = \sin(n+1)\theta/\sin\theta$. Thus we should consider the product $P_n^{\lambda+1}(x) P_m^\lambda(x)$. We show that

$$P_n^{\lambda+1}(x) P_m^\lambda(x) = \sum_{k=0}^{\min(n+1,m)} \beta_k P_{n+m-2k}^{\lambda+1}(x),$$

where β_k is given explicitly and that $\beta_k \geqq 0$ if $n \geqq m-1$. Recall that $(m+\lambda)P_m^\lambda(x) = \lambda[P_m^{\lambda+1}(x) - P_{m-2}^{\lambda+1}(x)]$, [1, p. 178, (36)]. In what follows $\alpha_k = \alpha_k^{\lambda+1}$ and $h_k = h_k^{\lambda+1}$. Using (1) we see that

A DIRECT PROOF OF STIRLING'S FORMULA

WILLIAM FELLER, Princeton University

1. Introduction. The main excuse for returning once more to the much belabored subject of Stirling's formula is not the simplicity and directness of the following approach, but the circumstance that it provides good illustrations for several topics and techniques of importance. It seems to me that for teaching purposes the discussion is of considerably greater interest than Stirling's formula as such.

The following derivation is self-contained and conceptual. The only formula of calculus used explicitly is

$$I(x) = \int_0^x \log y \, dy = x \log x - x, \tag{1.1}$$

and this can be avoided by expressing the exponent in (2.1) in terms of $I(n)$. Wallis' formula is not used, but the argument leads without artifice to an integral involving the function ϕ defined by

$$\phi(t) = t \prod_{k=1}^{\infty} \left(1 - \frac{t^2}{k^2}\right). \tag{1.2}$$

It is a lucky circumstance that this is the well-known product expansion for the sine:

$$\phi(t) = \frac{\sin \pi t}{\pi} \cdot \tag{1.3}$$

This classical identity is usually proved by relatively deep complex variable methods, but in Section 3 it is shown how the identity can be made plausible, and then proved, by simple elementary methods. The proof merely paraphrases the elegant argument used by E. Artin in his lectures to derive the partial fraction expansion for the cotangents. The whole note is in the spirit of E. Artin to whose cherished memory it is dedicated.

2. Stirling's formula states that

$$n! \sim \sqrt{2\pi}\, n^{n+\frac{1}{2}} e^{-n}. \tag{2.1}$$

The sign $\sim$ indicates that the ratio of the two sides tends to unity. To see how this relation arises naturally we start from the beginning: The problem is to find some estimate for $\log n!$

It is natural to interpret the sum $\log 1 + \cdots + \log n$ as an integral of the step function L which equals $\log k$ in the unit interval centered at k. Our problem is then to appraise the integral of the difference $L(x) - \log x$. In order to deal only with positive integrands we consider separately the several intervals of length $\frac{1}{2}$ in which this difference has a constant sign. Accordingly we put

$$a_k = \tfrac{1}{2}\log k - \int_{k-\frac{1}{2}}^{k} \log x\,dx = \int_{k-\frac{1}{2}}^{k} \log (k/x)dx \tag{2.2}$$

$$b_k = \int_{k}^{k+\frac{1}{2}} \log x\,dx - \tfrac{1}{2}\log k = \int_{k}^{k+\frac{1}{2}} \log (x/k)dx. \tag{2.3}$$

With the abreviation (1.1) we have then

$$a_1 - b_1 + a_2 - b_2 + - \cdots + a_n = \log n! - \tfrac{1}{2}\log n + I(n) - I(\tfrac{1}{2}). \tag{2.4}$$

But

$$a_k = \int_0^{\frac{1}{2}} \log \frac{1}{1-(t/k)}\,dt, \qquad b_k = \int_0^{\frac{1}{2}} \log\left(1+\frac{t}{k}\right)dt, \tag{2.5}$$

and it is seen trivially that $a_k > b_k > a_{k+1} > 0$. The left side in (2.4) is therefore a partial sum of an alternating series $\Sigma(-1)^k c_k$ with c_k decreasing monotonically to 0. The series therefore converges to a finite sum S, and (2.4) shows that

$$\log n! - (n+\tfrac{1}{2})\log n + n \to S - I(\tfrac{1}{2}). \tag{2.6}$$

This is Stirling's formula, except that the coefficient $\sqrt{2\pi}$ is replaced by the constant e^C where

$$C = \sum_{k=1}^{\infty} (a_k - b_k) - I(\tfrac{1}{2}). \tag{2.7}$$

[From this C could be calculated to any number of decimals, and in principle our problem is solved. It is also easy to obtain bounds on the error τ_n defined as the difference between the left side and the right side in (2.6). This τ_n is the remainder of our alternating series and hence $0 < \tau_n < b_n$. Since $\log(1+x) \leqq x$ this implies $0 < \tau_n < 1/8n$. This argument can be sharpened, but it is preferable to use the simple and elegant argument of H. E. Robbins which shows that $1/(12n+1) < \tau_n < 1/12n$. (See this MONTHLY, 62 (1955) 26–29)].

It is just a lucky circumstance that C reduces to a familiar constant. Indeed,

$$a_k - b_k = -\int_0^{\frac{1}{2}} \log\left(1 - \frac{t^2}{k^2}\right)dt \tag{2.8}$$

and so (2.7) expresses C as an integral of $-\log \phi(t)$, with ϕ defined in (1.2). In order not to interrupt the argument let us assume (1.3) as known. Then

$$C = -\int_0^{\frac{1}{2}} \log \frac{\sin \pi t}{\pi}\,dt = \frac{1}{2}\log \pi - \int_0^{\frac{1}{2}} \log \sin \pi t\,dt. \tag{2.9}$$

The last integral can be evaluated by considering the familiar symmetries of the sine and cosine. Obviously the value of the integral remains unchanged if $\sin \pi t$ is replaced by $\cos \pi t$, and hence, by the double angle formula

$$\int_0^{\frac{1}{2}} \sin 2\pi t\, dt = \tfrac{1}{2}\log 2 + 2\int_0^{\frac{1}{2}} \sin \pi t\, dt. \tag{2.10}$$

Again, the two integrals in (2.10) are trivially equal, and hence $= -\frac{1}{2}\log 2$. Accordingly $C = \frac{1}{2}\log 2\pi$, as asserted.

3. Proof of the identity (1.3). When the product for ϕ is decomposed into linear factors one notices immediately that $\phi(x+1) = -\phi(x)$. Thus ϕ is an odd periodic function having the same period and same zeros as $\pi^{-1}\sin \pi x$. One may therefore suspect that the two functions are the same. This suspicion becomes virtual certainty when one notices that in the product for $\phi(2x)$ the factor corresponding to $k = 2\nu$ coincides with the νth factor in (1.2), and so

$$\phi(2x) = 2\phi(x)\psi(x) \tag{3.1}$$

with

$$\psi(x) = \prod_{\nu=1}^{\infty}\left(1 - \frac{x^2}{(\nu - \frac{1}{2})^2}\right). \tag{3.2}$$

The decomposition (3.1) resembles the double angle formula for $\sin \pi x$ and leads to the suspicion that $\psi(x) = \cos \pi x$. Now it is easily verified that

$$\psi(x) = \frac{\phi(x + \frac{1}{2})}{\phi(\frac{1}{2})} \tag{3.3}$$

and this is exactly the relation between $\cos \pi x$ and $\pi^{-1}\sin \pi x$. Thus (3.1) reduces to the form of the double angle formula.

After these preparations it is easy to prove the identity (1.3) using Artin's elegant argument. Put

$$f(x) = \log\frac{\pi\phi(x)}{\sin \pi x}. \tag{3.4}$$

The fraction on the right is defined for nonintegral x, but it is easily seen that f is continuous at the origin if we put $f(0) = 0$. Thus f becomes a continuous periodic function. The double angle formulas for ϕ and $\pi^{-1}\sin \pi x$ imply that

$$f(2x) = \frac{f(x) + f(x + \frac{1}{2})}{2}. \tag{3.5}$$

Let m be the maximum of f. It follows from (3.5) that $f(2x) = m$ implies $f(x) = m$, and hence the maximum is assumed at a sequence of points converging to 0. But $f(0) = 0$, and hence f vanishes identically.

This paper is connected with research sponsored by the U. S. Army Research Office (Durham) at Princeton University.

in our sense with $\boldsymbol{S}$ the class of all subsets of X. Such a weight, if nonvacuous, is just the dual of a filter in $\boldsymbol{S}$.

Following Kimber, we call a point b of X a *barypoint* for a set I whenever UI belongs to $\boldsymbol{H}$ for every neighborhood U of b.

KIMBER'S THEOREM. *Every topologically bounded, heavy subset I of X has a barypoint in X.*

Proof. The Boolean algebra $\boldsymbol{A}$ generated by $\boldsymbol{S}$ contains a neighborhood base for every point in X since $\boldsymbol{A}$ is closed under finite intersection and $\boldsymbol{S}$ contains subbasic neighborhoods. Let $\boldsymbol{B}$ be the Boolean algebra with unit I consisting of all AI with A in $\boldsymbol{A}$. We contend that the heavy members of $\boldsymbol{B}$ form the dual $\boldsymbol{F}^*$ of some filter $\boldsymbol{F}$ in $\boldsymbol{B}$. Indeed, (i)* and (ii)* are clear. (iii)* follows from the identities $AI \cup BI = AI + (B - AB)I = BI + (A - BA)I$ and $AI = ABI + (A - AB)I$ for A, B in $\boldsymbol{A}$ since the terms joined by plus signs are $\boldsymbol{A}$-separated and, by our lemma, $\boldsymbol{H}$ is $\boldsymbol{A}$-conservative. Since the members of $\boldsymbol{F}$ lie in a compact set they must, by (i), (ii) and (iii), have a common cluster point b. That is, every neighborhood of b meets every member of $\boldsymbol{F}$. Now an arbitrary neighborhood U of b contains some neighborhood A of b belonging to $\boldsymbol{A}$. Thus AI belongs to $\boldsymbol{B}$ and meets every member of $\boldsymbol{F}$. That is, AI belongs to $\boldsymbol{F}^*$, hence to $\boldsymbol{H}$. Since $UI = AI + (U - A)I$ with the right-hand terms $\boldsymbol{A}$-separated, our lemma implies that UI is heavy; hence b is a barypoint for I.

THE FUNCTIONAL EQUATION $f(a+b, b) = f(a, a+b)$

S. K. STEIN, University of California at Davis

In this note we solve the functional equation

$$f(a + b, b) = f(a, a + b). \tag{1}$$

More precisely, we will use the Galois theory to exhibit three polynomials that generate all rational functions f with real coefficients that satisfy the equation.

Let F denote the field of real numbers, $F[x, y]$ the ring of polynomials in x and y over F, and $F(x, y)$ the field of rational functions in x and y over F. Consider a rational function $f \in F(x, y)$ that satisfies (1), or equivalently,

$$f(x, y) = f(x - y, x). \tag{2}$$

Define the automorphism T: $F(x, y) \to F(x, y)$ by setting $T(x) = x - y$ and $T(y) = x$. We are interested in the field F^* of elements fixed under T.

Straightforward computations show that

$$T(x) = x - y, \quad T^2(x) = -y, \quad T^3(x) = -x,$$
$$T^4(x) = -x + y, \quad T^5(x) = y, \quad T^6(x) = x.$$

From this it follows that $T^6(y) = y$ and hence $T^6 = I$, the identity automorphism of $F(x, y)$. Thus we have $[F(x, y): F^*] = 6$.

It might be conjectured that the six elementary symmetric functions of $T(x)$, $T^2(x)$, $\cdots$, $T^6(x)$ would generate F^*. However, consider

$$\prod_{i=1}^{6} [w - T^i(x)] = (w^2 - x^2)(w^2 - y^2)(w^2 - (y - x)^2). \tag{3}$$

Letting $S_j (j=1, 2, \cdots, 6)$ be the jth elementary symmetric function of $T(x)$, $T^2(x)$, $\cdots$, $T^6(x)$, we see from (3) that $S_1 = S_3 = S_5 = 0$ and

$$S_2 = 2x^2 - 2xy + 2y^2$$
$$S_4 = x^2y^2 + x^2(x - y)^2 + y^2(x - y)^2$$
$$S_6 = x^2y^2(x - y)^2.$$

We note that $S_4 = (1/4)(S_2)^2$. Thus $F(S_1, S_2, S_3, S_4, S_5, S_6) = F(S_2, S_6) \subseteq F^* \subset F(x, y)$. To determine whether $F(S_2, S_6) = F^*$ we compute $[F(x, y): F(S_2, S_6)]$. Since x is a root of (3), which is an equation of degree 6 having coefficients in $F(S_2, S_6)$, and y is a root of an equation of degree 2 having coefficients in $F(S_2, S_6, x)$ (since $2x^2 - 2xy + 2y^2 - S_2 = 0$), we have

$$[F(x, y): F(S_2, S_6)] \leqq 12.$$

On the other hand, $[F(x, y): F(S_2, S_6)] \geqq 12$, since the group of automorphisms of $F(x, y)$ over $F(S_2, S_6)$ includes not only the group of order 6 generated by T, but also the automorphism C defined by $C(x) = y$, $C(y) = x$. Thus $[F(x, y): F(S_2, S_6)] = 12$ and consequently $[F^*: F(S_2, S_6)] = 2$. Thus S_2 and S_6 do not generate F^*. Now, the polynomial

$$P = xy(x - y)(x^3 - x^2y - 2xy^2 + y^3)$$

is fixed under T but not under C. Thus $F^* = F(S_2, S_6, P)$ and the problem is solved. The extra generator P is needed, since S_2 and S_6 have excessive symmetry, being fixed not only under T, used in their construction, but also under C.

ON FINITE NEAR-RINGS WITH IDENTITY

C. J. Maxson, State University College, Fredonia, N. Y.

A near-ring $(N, +, *)$ is a mathematical system having the following properties:

(1) $(N, +)$ is a group
(2) $(N, *)$ is a semi-group
(3) $(a+b) * c = a * c + b * c$ $\qquad a, b, c \in N.$

In [1], J. R. Clay showed how to construct all near-rings whose additive groups are finite and cyclic. We show here that if such a near-ring has a multiplicative identity e then this near-ring is a ring. We also show (Proposition 3) that if the cardinality of the set N is the product of distinct primes then the near-ring $(N, +, *)$ with identity e is a ring.

It might be conjectured that the six elementary symmetric functions of $T(x)$, $T^2(x)$, $\cdots$, $T^6(x)$ would generate F^*. However, consider

$$\prod_{i=1}^{6} [w - T^i(x)] = (w^2 - x^2)(w^2 - y^2)(w^2 - (y - x)^2). \tag{3}$$

Letting $S_j (j=1, 2, \cdots, 6)$ be the jth elementary symmetric function of $T(x)$, $T^2(x)$, $\cdots$, $T^6(x)$, we see from (3) that $S_1 = S_3 = S_5 = 0$ and

$$S_2 = 2x^2 - 2xy + 2y^2$$
$$S_4 = x^2y^2 + x^2(x - y)^2 + y^2(x - y)^2$$
$$S_6 = x^2y^2(x - y)^2.$$

We note that $S_4 = (1/4)(S_2)^2$. Thus $F(S_1, S_2, S_3, S_4, S_5, S_6) = F(S_2, S_6) \subseteq F^* \subset F(x, y)$. To determine whether $F(S_2, S_6) = F^*$ we compute $[F(x, y): F(S_2, S_6)]$. Since x is a root of (3), which is an equation of degree 6 having coefficients in $F(S_2, S_6)$, and y is a root of an equation of degree 2 having coefficients in $F(S_2, S_6, x)$ (since $2x^2 - 2xy + 2y^2 - S_2 = 0$), we have

$$[F(x, y): F(S_2, S_6)] \leqq 12.$$

On the other hand, $[F(x, y): F(S_2, S_6)] \geqq 12$, since the group of automorphisms of $F(x, y)$ over $F(S_2, S_6)$ includes not only the group of order 6 generated by T, but also the automorphism C defined by $C(x) = y$, $C(y) = x$. Thus $[F(x, y): F(S_2, S_6)] = 12$ and consequently $[F^*: F(S_2, S_6)] = 2$. Thus S_2 and S_6 do not generate F^*. Now, the polynomial

$$P = xy(x - y)(x^3 - x^2y - 2xy^2 + y^3)$$

is fixed under T but not under C. Thus $F^* = F(S_2, S_6, P)$ and the problem is solved. The extra generator P is needed, since S_2 and S_6 have excessive symmetry, being fixed not only under T, used in their construction, but also under C.

ON FINITE NEAR-RINGS WITH IDENTITY

C. J. Maxson, State University College, Fredonia, N. Y.

A near-ring $(N, +, *)$ is a mathematical system having the following properties:

(1) $(N, +)$ is a group

(2) $(N, *)$ is a semi-group

(3) $(a+b) * c = a * c + b * c$ $\qquad a, b, c \in N.$

In [1], J. R. Clay showed how to construct all near-rings whose additive groups are finite and cyclic. We show here that if such a near-ring has a multiplicative identity e then this near-ring is a ring. We also show (Proposition 3) that if the cardinality of the set N is the product of distinct primes then the near-ring $(N, +, *)$ with identity e is a ring.

is a sub-near-ring of $(N, +, *)$. In fact $(N', +, *)$ is a commutative ring with identity $1 \cdot e$ and $(N', +, *) \cong (Z_{n_e}, +, \cdot)$ where $n_e = O(e)$. This gives us

PROPOSITION 4. *If $(N, +, *)$ is a near-ring with identity e then $(N, +, *)$ contains a nontrivial commutative ring. If $O(e)$ is not finite then $(Z, +, \cdot)$ is a sub-ring of $(N, +, *)$ where Z denotes the set of integers.*

COROLLARY 5. *If $(N, +, *)$ is a near-ring with identity e and $\|N\| = P$ where P is a prime then $(N, +, *)$ is a field.*

Proof. From Lemma 2, $O(e) = P$. Therefore $(N', +, *) \cong (Z_p, +, \cdot)$ which shows that $\|N'\| = P$. Thus $(N', +, *) = (N, +, *)$.

We conclude with a result in which $\|N\|$ is not finite. Let $\{(N_i, +, *)\}$, $i = 1, 2, 3, \cdots$ be a family of near-rings such that $(N_i, +)$ is a cyclic group of order p^i and $(N_i, +, *)$ is a sub-near-ring of $(N_{i+1}, +, *) i = 1, 2, 3, \cdots$. Let $(N, +, *) = \bigcup_{i=1}^{\infty} (N_i, +, *)$. It is clear that $(N, +, *)$ is a near-ring.

PROPOSITION 6. *The near-ring $(N, +, *)$ defined above is a ring if it contains an identity e.*

Proof. Since $e \in N$, $e \in N_{i_0}$ for some i_0. Whence N_{i_0} is a ring. Thus for $j \leqq i_0$, N_j is also a ring. Furthermore since e is an identity for N, e is an identity for N_k, $k \geqq i_0$, and so these N_k are rings. This shows that $(N_i, +, *)$ is a ring for $i = 1, 2, 3, \cdots$ and whence $(N, +, *)$ is a ring.

This work was done while the author was an NSF fellow at SUNY at Buffalo.

A CHARACTERIZATION OF ALMOST UNIFORM CONVERGENCE

N. Y. LUTHER, Washington State University

The author is unable to find the following result explicitly in print (notation and terminology as in the reference [1]):

THEOREM. *Let f_n, f be real valued measurable functions on a measure space (X, S, μ). In order that $f_n \to f$ almost uniformly, it is necessary and sufficient that for each $\epsilon > 0$,*

$$\lim_{n \to \infty} \mu\left(\bigcup_{m \geqq n} \{x; |f_m(x) - f(x)| \geqq \epsilon\} \right) = 0.$$

Proof: Let $E_n(\epsilon) = \{x; |f_n(x) - f(x)| \geqq \epsilon\}$ $(\epsilon > 0, n = 1, 2, \cdots)$. To prove necessity, we fix $\epsilon > 0$ and show that $\lim_{n \to \infty} \mu(\bigcup_{m \geqq n} E_m(\epsilon)) = 0$: Let $\delta > 0$. By hypothesis, there is a measurable set F such that $\mu(F) < \delta$ and f_n converges to f uniformly on F'. Hence there is a positive integer N such that $F' \subset \bigcap_{m \geqq N} E_m(\epsilon)'$; i.e., $\bigcup_{m \geqq N} E_m(\epsilon) \subset F$. It follows that $\mu(\bigcup_{m \geqq n} E_m(\epsilon)) < \delta$ for all $n \geqq N$.

To show sufficiency, we let $\delta>0$ and exhibit a measurable set F such that $\mu(F)<\delta$ and f_n converges to f uniformly on F': By hypothesis, we have for each positive integer p a positive integer $N(p)$ such that $\mu(\bigcup_{m\geq N(p)} E_m(1/p))<\delta/2^p$. Let $F=\bigcup_{p\geq 1}\bigcup_{m\geq N(p)} E_m(1/p)$. Then $\mu(F)<\delta$ and clearly f_n converges to f uniformly on $F'=\bigcap_{p\geq 1}\bigcap_{m\geq N(p)} E_m(1/p)'$.

An interesting feature of this characterization is that it fully exposes the relationship between almost uniform convergence, convergence in measure, and almost everywhere convergence since the last mentioned is characterized by the condition that for every $\epsilon>0$,

$$\mu\left(\bigcap_{n\geq 1}\bigcup_{m\geq n}\{x;\ |f_m(x)-f(x)|\geq\epsilon\}\right)=0.$$

As an example, one by-product of this approach is Egoroff's Theorem [1, 21.A].

CORRECTION FOR "THE INTERVAL TOPOLOGY AND ORDER CONVERGENCE AS DUAL CONVERGENCE STRUCTURES"

D. C. KENT, Washington State University

It has been called to my attention by Professor Jorg Mayer that the proof of Theorem 2 in my paper, (Vol. 74, No. 4 (1967) 426–427) is incorrect. The corrected proof is given below.

THEOREM 2. (As stated.)

Proof. (1) Let $\mathfrak{F}$ be an ultrafilter on S which converges to x with respect to the topology t described above, and $y\notin x^+$. Then the complement of y^* is in $\mathfrak{F}$, which implies that y^* is not in $\mathfrak{F}$, and hence $y\notin\mathfrak{F}^+$. Thus $x^+\supset\mathfrak{F}^+$, and $x^{+*}=x^*\subset\mathfrak{F}^{+*}$. By a similar argument, $x^+\subset\mathfrak{F}^{*+}$, and $\mathfrak{F}$ p-converges to x. Conversely, assume that an ultrafilter $\mathfrak{F}$ p-converges to x. Then $x^*\subset\mathfrak{F}^{+*}$ implies that $x^+\supset\mathfrak{F}^{+*+}$. Assume that $y\notin x^+$; then $y\notin\mathfrak{F}^{+*+}$, and $y^*\supset\mathfrak{F}^{+*}$. On the other hand, if $y^*\in\mathfrak{F}$, then $y\in\mathfrak{F}^+$, and $y^*\supset\mathfrak{F}^{+*}$. This contradiction establishes that the complement of y^* is in $\mathfrak{F}$, and we conclude that $\mathfrak{F}$ t-converges to x.

Erratum: (March 1967 issue, page 297 "A Lower Bound for the Number of Vertices of a Graph" by M. E. Watkins) Theorem 1 should read:

If G is a graph on n vertices with connectivity $\lambda\geq 1$ and diameter $\delta\geq 1$, then $n\geq\lambda(\delta-1)+2$.

To show sufficiency, we let $\delta>0$ and exhibit a measurable set F such that $\mu(F)<\delta$ and f_n converges to f uniformly on F': By hypothesis, we have for each positive integer p a positive integer $N(p)$ such that $\mu(\bigcup_{m\geq N(p)} E_m(1/p))<\delta/2^p$. Let $F=\bigcup_{p\geq 1}\bigcup_{m\geq N(p)} E_m(1/p)$. Then $\mu(F)<\delta$ and clearly f_n converges to f uniformly on $F'=\bigcap_{p\geq 1}\bigcap_{m\geq N(p)} E_m(1/p)'$.

An interesting feature of this characterization is that it fully exposes the relationship between almost uniform convergence, convergence in measure, and almost everywhere convergence since the last mentioned is characterized by the condition that for every $\epsilon>0$,

$$\mu\left(\bigcap_{n\geq 1}\bigcup_{m\geq n}\{x;\ |f_m(x)-f(x)|\geq\epsilon\}\right)=0.$$

As an example, one by-product of this approach is Egoroff's Theorem [1, 21.A].

NOTE ON A THEOREM OF BLAKE AND AARON

IRVING KATZ, George Washington University

THEOREM. *Let the Farey sequence F_n be written $f_0=x_0/y_0$, $f_1=x_1/y_1$, $\cdots$, $f_m=x_m/y_m$ in ascending order (so that $x_0/y_0=0/1$ and $x_m/y_m=1/1$). Then f_0, f_1, $\cdots$, f_t satisfy $\sum_{i=0}^{t} x_i/\sum_{i=0}^{t} y_i=1/2$ if and only if $t=m$.*

Proof. $\sum_{i=0}^{t} x_i/\sum_{i=0}^{t} y_i=1/2$ if and only if

$$0 = \sum_{i=0}^{t} (y_i - 2x_i) = \sum_{i=0}^{t} 2y_i(1/2 - x_i/y_i).$$

Moreover, using Lemmas 3 and 1 of [1], we note

$$y_i = y_{m-i}, \qquad 1/2 - x_i/y_i = x_{m-i}/y_{m-i} - 1/2.$$

If $i<m/2$, then $1/2-x_i/y_i>0$ and so it follows that $\sum_{i=0}^{t} 2y_i(1/2-x_i/y_i)=0$ if and only if $t=m$.

The sufficiency was first established by Blake. We may prove the sufficiency independently of Blake's argument by noting that $\phi(i)$ terms of F_n have denominator i and that

$$\sum_{\substack{1\le j\le i \\ (i,j)=1}} j = i\phi(i)/2$$

and so

$$\sum_{i=0}^{m} x_i \Big/ \sum_{i=0}^{m} y_i = \frac{1 + 2\phi(2)/2 + \cdots + n\phi(n)/2}{2 + 2\phi(2) + \cdots + n\phi(n)} = 1/2.$$

DIRECTED GRAPHS WITH TRANSITIVE ABELIAN GROUPS

R. L. HEMMINGER, Vanderbilt University

Chao [Proc. Amer. Math. Soc., 15 (1964) 291–292] proved that if P is a transitive, abelian, nonelementary 2-permutation group then P does not have an undirected graph (i.e., there does not exist an undirected graph X such that $G(X)=P$ where $G(X)$ is the group of automorphisms of X). In this paper we prove

THEOREM 1. *If P is a transitive abelian permutation group abstractly isomorphic to $\oplus \sum C(n_{ij})$ where $1\le j\le m_i$, $i=1, \cdots, k$, $n_1<n_2< \cdots <n_k$, $C(n_{ij})$ are the integers* mod n_i, *$m_1\neq 2$, 3, or 4 if $n_1=2$, and $m_i\neq 2$ if $n_i=3$, then P has a directed graph.*

It is also noted that the results of Sabidussi [Proc. Amer. Math. Soc., 9 (1958) 800–804] hold for directed graphs. In particular we get

THEOREM 2. *If $G(X)$ is a regular permutation group for a directed graph X, X different from the null graph on two vertices, then X is connected and isomorphic to $X_{G(X),H}$ for some set H of generators for $G(X)$. $X_{G(X),H}$ is the graph with vertex set $G(X)$ and edge set $\{(g, g+h) \mid g \in G(X), h \in H\}$.*

The proof of Theorem 1 involves showing that the set of left additions, $L(G)$, of G equals $G(X_{G,H})$, where $G = \oplus \sum C(n_{ij})$, the $C(n_{ij})$ as in the theorem, and $H = \bigcup_{u=1}^{k} H_u$ where $H_u = \{1_{ui} - 1_{uj},\ 1_{ui} + 1_{uj},\ 1_{up} \mid 1 \leqq i < j \leqq m_u,\ 1 \leqq p \leqq m_u\}$. ($1_{ij}$ is the element of G that equals 1 in the ijth component and zero elsewhere). The theorem follows since P is regular; for then P and $L(G)$ are isomorphic as permutation groups.

Theorem 1 has the following corollary which is pertinent in the elementary 2-group case in Chao's paper mentioned above.

COROLLARY. *Let H be a minimal set of generators for a finite abelian group G. Then $L(G) = G(X_{G,H})$ if and only if distinct elements of H have distinct orders.*

A NOTE ON THE NUMBER OF IDEMPOTENT ELEMENTS IN SYMMETRIC SEMIGROUPS

BERNARD HARRIS, University of Wisconsin

The set of all mappings of a finite set into itself is a semigroup under composition called the symmetric semigroup on n elements and denoted by T_n. This note gives a derivation of the exponential generating function of the number of idempotent elements U_n in T_n. For every idempotent mapping, there is a partition of the n points into components; let k_i, $i = 1, 2, \cdots, n$ be the number of components with i elements, and let $N(k_1, k_2, \cdots, k_n)$ be the number of idempotent elements of T_n with the indicated partition, where $\sum ik_i = n$. It can be shown that the enumeration of idempotent elements is equivalent to the enumeration of forests of rooted labeled trees of height at most one. $r = \sum k_i$ is the number of components (rooted labeled trees). From this, we have

$$N(k_1, k_2, \cdots, k_n)/n! = \frac{1^{k_1}2^{k_2} \cdots n^{k_n}}{1!^{k_1}2!^{k_2} \cdots n!^{k_n}k_1!k_2! \cdots k_n!}, \qquad \sum ik_i = n.$$

Defining,

$$\psi(x_1, x_2, \cdots) = \exp\left(\sum_{i=1}^{\infty} x_i/(i-1)!\right)$$

it follows that $N(k_1, k_2, \cdots, k_n)$ is the coefficient of $(1/n!)x^n t_1^{k_1} t_2^{k_2} \cdots t_n^{k_n}$ in $\psi(t_1x, t_2x^2, \cdots, t_nx^n, 0, 0, \cdots)$. The number of idempotents of rank r in T_n is the coefficient of

$$\frac{1}{n!}\, x^n t^r \text{ in } \psi(tx, tx^2, \cdots, tx^n, 0, 0, \cdots) = e^{txe^x}.$$

A NOTE ON COMMUTATORS AND QUOTIENT GROUPS

L. C. GROVE, University of Oregon

If G is a group and $n>1$ is any cardinal number, let us denote by G^n the weak direct product of n copies of G. Thus for some set I with cardinality n, G^n is the subgroup of the cartesian product $\prod\{G: \alpha\in I\}$ consisting of all elements g such that $g(\alpha)=1$ for all but finitely many $\alpha\in I$. Denote by H the subgroup of G^n generated by the set of all elements g for which there are $\alpha, \beta\in I$, with $\alpha\neq\beta$, and $x\in G$ such that $g(\alpha)=x$, $g(\beta)=x^{-1}$, and $g(\gamma)=1$ if $\gamma\neq\alpha, \beta$.

THEOREM. *If G, n, and H are as above, then H is a normal subgroup of G^n and the quotient group G^n/H is independent of n. In fact, G^n/H is isomorphic with G/G', where G' is the commutator subgroup of G.*

Proof. For each $g\in G^n$ set $f(g)=\prod_\alpha g(\alpha)G'$. Then f is a homomorphism on G^n onto G/G', and it is clear that $H\subseteq\ker f$. If $g\in\ker f$, with $g(\alpha_i)=y_i$, $i=1, \cdots, k$, and $g(\alpha)=1$ otherwise, then by [1], p. 25, there exist $x_1, \cdots, x_m\in G$ such that

$$\prod_{i=1}^{k} y_i = \prod_{i=1}^{m} x_i \prod_{i=1}^{m} x_i^{-1}.$$

Choose $\beta\neq\alpha_k$ and define $g_i(\alpha_k)=x_i$, $g_i(\beta)=x_i^{-1}$, and $g_i(\alpha)=1$ otherwise, $1\leqq i\leqq m$. Define $g_{m+1}(\alpha_k)=\prod_{i=1}^{m} x_i^{-1}$, $g_{m+1}(\beta)=\prod_{i=0}^{m-1} x_{m-i}$, and $g_{m+1}(\alpha)=1$ otherwise. Set $h=\prod_{i=1}^{m+1} g_i$. Next define $h_i(\alpha_i)=y_i$, $h_i(\alpha_k)=y_i^{-1}$, and $h_i(\alpha)=1$ otherwise, $1\leqq i\leqq k-1$. It is not hard to see that h, $h_i\in H$ and that $g=h_{k-1}\cdots h_1 h$. Thus $H=\ker f$ and the theorem is proved.

A NOTE ON UNCONDITIONALLY CONVERGENT SERIES

H. P. YAP, University of Singapore

In this note we shall prove the following

THEOREM. *Let $\sum_{i=0}^{\infty} a_i$ be an absolutely convergent numerical series which converges to a, and $\sum_{i=0}^{\infty} x_i$ be an unconditionally convergent series in a Banach space B such that $\sum_{i=0}^{\infty} x_i = x$. Then*

(1) $a_0x_0 + a_0x_1 + a_1x_0 + a_0x_2 + a_1x_1 + a_2x_0 + a_0x_3 + a_1x_2 + a_2x_1 + a_3x_0 + \cdots$

converges to ax unconditionally.

Proof. Let $\sum_{i=0}^{\infty}|a_i| = A$. Since $\sum_{i=0}^{\infty} x_i$ is unconditionally convergent, therefore by applying a theorem in [1] we can prove that there exists a constant $K>0$ such that $\sum_{i=0}^{\infty}|f^*(x_i)| \leqq K$ for every $f^* \in B^*$ (the conjugate space of B) satisfying $\|f^*\| = 1$. Now, for any $\epsilon>0$, there exist positive integers N_1, N_2 such that $\sum_{i=p}^{\infty}|a_i| < \epsilon/2K$ for all $p \geqq N_1$ and whenever $\|f^*\| = 1$, $\sum_{j=q}^{\infty}|f^*(x_j)| < \epsilon/2A$ for all $q \geqq N_2$.

Let $N_3 = \max(N_1, N_2)$. Then for every f^* satisfying $\|f^*\| = 1$, we have

$$\sum_{p+q \geq N_3}^{\infty} |f^*(a_p x_q)| \leqq \left(\sum_{i=0}^{\infty} |a_i|\right)\left(\sum_{j=N_3}^{\infty} |f^*(x_j)|\right) + \left(\sum_{i=N_3}^{\infty} |a_i|\right)\left(\sum_{j=0}^{\infty} |f^*(x_j)|\right) < \epsilon.$$

This shows that (1) is unconditionally convergent [1]. Since (1) is convergent, therefore

(2) $$a_0x_0 + (a_0x_1 + a_1x_0) + (a_0x_2 + a_1x_1 + a_2x_0) + \cdots$$

is also convergent.

By [2], (2) converges to ax.

Finally, it is well known that if (1) is convergent, then (2) converges to the same sum as (1). Hence (1) converges to ax.

ON THE TRIANGULAR FORM OF A LINEAR TRANSFORMATION

C. L. SUFFEL, Polytechnic Institute of Brooklyn

Every linear transformation on a finite dimensional vector space defined over an algebraically closed field has a triangular form. Equivalent conditions for the existence of a triangular form, when the field is arbitrary, are given in the following theorem:

THEOREM. *If V is a finite dimensional vector space over the field F and the linear transformation, A, has characteristic polynomial $p(\lambda)$ then*:

(1) $$p(\lambda) = \prod_{i=1}^{k} (\lambda - \lambda_i)^{r_i}$$

i.e., $p(\lambda)$ factors completely in $F[\lambda] \Leftrightarrow$(2) A has a triangular form $\Leftrightarrow$(3) $\{\alpha \in F \mid \alpha$ is an eigenvalue of $f(A)\} = \{f(\beta) \in F \mid \beta$ is an eigenvalue of $A\}$ for all $f \in F[\lambda]$.

Proof. (1)$\Rightarrow$(2): With minor modifications the proof for the algebraically closed case applies here. (2)$\Rightarrow$(3): see [1].

(3)$\Rightarrow$(1) If $r(\lambda)$ is any nonscalar, monic, irreducible factor of $m(\lambda)$, the minimal polynomial of A, then there exists a polynomial, $h(\lambda)$, with degree strictly less than $m(\lambda)$, such that $m(\lambda) = r(\lambda)h(\lambda)$. Since $m(\lambda)$ is the minimal polynomial of A, there exists a nonzero vector y, such that $h(A)(y) \neq 0$. Hence "0" is an eigenvalue of $r(A)$ and by (3) an eigenvalue of A exists such that $r(\beta) = 0$. Since $r(\lambda)$ is monic and irreducible in $F[\lambda]$, $r(\lambda) = \lambda - \beta$. Finally (1) follows because every irreducible factor of $p(\lambda)$ is a factor of $m(\lambda)$; see [2].

ANOTHER CHARACTERIZATION OF THE JACOBSON RADICAL

T. L. JENKINS, University of Wyoming

Let A be an arbitrary ring and I a proper (left, right) ideal of A. If $A^n \subseteq I$ for some integer $n \geq 2$, I is called a *special* (left, right) *ideal.* If no such integer exists, I is called *nonspecial.* A is called a *left m-ring* if A has no nonspecial maximal left ideals (i.e. a maximal left ideal which is nonspecial). A left ideal I of A is a *left m-ideal* if, as a subring of A, I is a left m-ring. If a ring has no maximal left ideals it is clearly a left m-ring. Every nilpotent ring is a left m-ring.

THEOREM. *If I is a left m-ideal of the ring A then $I \subseteq J(A)$, the Jacobson radical of A. Furthermore, if $Q(A)$ denotes the ideal generated by the sum of all the left m-ideals of A then $Q(A) = J(A)$.*

COROLLARY 1. *A left m-ring is a right m-ring and conversely.*

COROLLARY 2. *Let A be a ring in which $J(A) \neq A$. Then there exists a maximal left ideal I of A such that for each positive integer n there exists an $x_n \in A^n$ such that $A = I + (x_n)_1$ where $(x_n)_1$ is the left ideal in A generated by x_n.*

Relative to the Kurosh-Amitsur terminology, the Jacobson radical class is characterized as the class of rings which are groups under the multiplication $a \circ b = a + b - ab$. From the theorem, this class can also be characterized as the class of all left m-rings.

Mail Address: Mathematics Department, 322 Hoyt Hall, University of Wyoming, Laramie, WY 82070.

A NOTE ON LEVI'S THEOREM

E. W. WALLACE, Leeds University, England

1. Introduction. We use the following lemma to show that there is an anti-commutative algebra for which Levi's theorem fails. The reader is referred to [1] for definitions and results.

LEMMA. *If R is an n-dimensional algebra with constants of structure C_{jk}^{i}, then a linear functional λ defines a subalgebra if, and only if, there is a linear functional μ such that*

$$C_{jk}^{i}\lambda_i = \lambda_j\mu_k - \lambda_k\mu_j \qquad (i, j, k = 1, \cdots, n).$$

(This is the most useful form of the lemma for calculations.)

2. An example for which Levi's theorem fails. Consider the 5-dimensional algebra P defined in Section 6 of [1]. It can be verified that $((e_5))$ is both the radical and centre of P. Using the lemma, we find that $((e_2, e_3, e_4, e_5))$ is the only subalgebra of dimension 4, and this is not semisimple, being solvable. Hence Levi's theorem fails for P.

3. Two examples for which Levi's theorem holds. On the other hand, the 4-dimensional algebra P defined in Section 7 of [1] has radical $\Gamma = ((e_1))$, and a simple subalgebra $S = ((e_2, e_3, e_4))$. It follows that Levi's theorem holds for P, although P is not a Lie algebra. In fact, the same is true of S, and it should be observed that S is not an ideal, so P is not merely the direct sum of Γ and S.

COMPACTNESS AND SEQUENTIAL COMPACTNESS IN METRIC SPACES

L. M. SIMON, University of Adelaide, Australia

The purpose of this article is to give a simple and fairly short proof of the fact that a sequentially compact subset of a metric space is compact. The procedure is straightforward enough to enable one to derive the Heine Borel Theorem for Euclidean space from the Bolzano-Weierstrass theorem.

Henceforth let X be a space with metric d, C a sequentially compact subset of X, and for each $x \in X$ and $\lambda > 0$ put $N(x, \lambda) = \{y; y \in X \text{ and } d(x, y) < \lambda\}$.

First the following lemma is needed.

LEMMA 1. *For each $\lambda > 0$ there exists a positive integer $n(\lambda)$ and a finite set $S_\lambda = \{x_1, \cdots, x_{n(\lambda)}\}$ with $S_\lambda \subset C$ and $C \subset \bigcup_{i=1}^{n(\lambda)} N(x_i, \lambda)$.*

This lemma is standard (see e.g. Baum: Elements of Point Set Topology, Prentice Hall, 1964 p. 122).

Next observe that some of the proofs of the Lebesgue covering lemma (Lemma 2 below) are valid for sequentially compact subsets of a metric space. (See e.g. Hocking and Young, Topology, Addison Wesley, 1961 p. 30; but note that their hypothesis of finite open covers is not used in the proof.) Thus we have

LEMMA 2. *Let* $\mathfrak{U}$ *be a collection of open sets covering* C. *Then there exists* $\lambda>0$ *such that, for every* $x\in C$, *there is a set* $U\in\mathfrak{U}$ *with* $N(x, \lambda)\subset U$.

We can now prove that C is compact.

Proof: Let $\mathfrak{U}$ be any collection of open sets covering C. By Lemma 2 there exists $\lambda'>0$ such that, for each $x\in C$, there is a $U\in\mathfrak{U}$ with $N(x, \lambda')\subset U$. But, by Lemma 1, there now exists a finite subset $\{x_1, \cdots, x_n\}$ of C such that $C\subset\bigcup_{i=1}^{n} N(x_i, \lambda')$. Then for each $i=1, \cdots, n$ let $U_i\in\mathfrak{U}$ be such that $N(x_i, \lambda')\subset U_i$.

It now follows that $C\subset\bigcup_{i=1}^{n} U_i$.

A GENERAL FORMULA FOR THE nth DERIVATIVE OF $1/f(x)$

P. SHIEH AND K. VERGHESE, North Carolina State University

A convenient recursion formula which we have derived for finding the nth derivative of $1/f(x)$ is shown below:

$$(1)\qquad D_n\left[\frac{1}{f(x)}\right]=\frac{d^n}{dx^n}\left[\frac{1}{f(x)}\right]=-\frac{n!}{f}\sum_{i=0}^{n-1}\frac{f_{n-i}D_i}{(n-i)!\,i!},\qquad n=1, 2, 3, \cdots,$$

where D_0 is defined to be $1/f(x)$ and f_n stands for the nth derivative of $f(x)$.

The proof by mathematical induction is straightforward. Equation (1) requires the determination of all the $(n-1)$ lower order derivatives of $1/f(x)$ in evaluating D_n. In order to remove this requirement, it may be written in the expanded form.

$$(2)\qquad D_n+\frac{f_n}{f^2}=\sum_{r=2}^{n}\frac{n!}{f^{r+1}}(-1)^r\left[\sum_{r_1=1}^{n-1}\frac{f_{n-r_1}}{(n-r_1)!}\sum_{r_2=1}^{r_1-1}\frac{f_{r_1-r_2}}{(r_1-r_2)!}\right.$$
$$\left.\sum_{r_3=1}^{r_2-1}\frac{f_{r_2-r_3}}{(r_2-r_3)!}\cdots\sum_{r_{r-1}=1}^{r_{r-2}-1}\frac{f_{r_{r-2}-r_{r-1}}}{(r_{r-2}-r_{r-1})!}\frac{f_{r_{r-1}}}{r_{r-1}!}\right]$$

for $n\geqq 1$. In using this formula it must be borne in mind that

$$\sum_{r_k=1}^{r_{k-1}-1}X_{r_k}=0\quad\text{if } r_{k-1}\leqq 1.$$

Equation (2) when used along with Leibnitz formula for the nth derivative of a product, yields the nth derivative of a quotient $g(x)/f(x)$. Then,

$$\frac{d^n}{dx^n}\frac{g(x)}{f(x)} = \frac{g_n}{f} + \sum_{r=1}^{n} \frac{n!}{(n-r)!\,r!} g_{n-r} D_r,$$

where g_n is the nth derivative of $g(x)$ and D_r is given by equation (2) or (1).

THE UPPER RADICAL DETERMINED BY REGULAR RINGS

T. L. JENKINS, University of Wyoming

An element a of a ring A is called *regular* if there exists an element $b \in A$ such that $a = aba$. A ring is called regular if all its elements are regular. The definition of a *radical class* is given in [1, p. 4] and of a *hereditary* radical class in [1, p. 125].

LEMMA 1. *The class R of all regular rings is a hereditary radical class.*

LEMMA 2. *Let J be the Jacobson radical class. Then $J \cap R = \varnothing$.*

LEMMA 3. *If M is the Brown-McCoy radical class then $M \not\subseteq R$, $R \not\subseteq M$, and $M \cap R \neq \varnothing$.*

LEMMA 4. *R is a radical class which does not coincide with the classical Wedderburn radical on rings having the D.C.C. on right ideals.*

In a manner similar to the one used by N. J. Divinsky [1, p. 5], the upper radical class V determined by R is constructed.

LEMMA 5. $J \subseteq V$.

LEMMA 6. *If $V \subseteq M$, then every simple ring with unit is regular.*

LEMMA 7. *Let A be a ring with unit which is not a division ring and in which the only idempotents are* 0 *and* 1. *Then A is not regular.*

That $V \not\subseteq M$ is established by exhibiting a simple ring with unit which is not a division ring and in which the only idempotents are 0 and 1. This then is the contrapositive of Lemma 6. N. Jacobson [3, p. 211] constructs such a ring and another may be found in [2, p. 237].

THEOREM: *$M \not\subseteq V$, $V \not\subseteq M$, and $M \cap V \neq \varnothing$.*

EDITORIAL NOTE ON "BETWEEN T_1 AND T_2"

Albert Wilansky asked in [1] whether a locally compact US space must be T_2. Many answers have been supplied in the form of letters, and manuscripts submitted for publication. There have been constructions by C. E. Aull, S. P. Franklin, R. Jones and G. Miller, Dennis G. King and George D. Poole, Mark Mandelker, Paul R. Meyer, John W. Taylor.

One of the examples is presented here. (Other constructions use sets of ordinals with the order topology and compactifications thereof.) Let X be a compact T_2 space which is not discrete but is such that no sequence of distinct points can converge. For example we might take $X=\beta N$. (See [1], examples 5, 6.) Let x be a nonisolated point of X and let Y be the same as X, but with x "doubled." (This means that an object $y\notin X$ is chosen; $Y=X\cup\{y\}$ so topologized that x, y have exactly the same deleted neighborhoods and the relative topology of X is its original topology.)

See also Problem 5444 in this MONTHLY, 74 (1967).

ON THE RING OF INTEGERS

A. HANNA, American University of Beirut

1. Introduction. The ring of integers is usually characterized as an integral domain A whose set of positive elements is well-ordered. A set of positive elements of a ring A is defined to be a subset P of A which is closed under addition and multiplication, and satisfies the following *trichotomy* condition:

(T) For each $a\in A$, exactly one of the following holds:

$$a \in P, \qquad a = 0, \qquad \text{or} \qquad -a \in P.$$

We will show that if a ring A has a subset P satisfying (T) and the *well-ordering* condition:

(W) Every nonempty subset S of P contains a *least element*, that is an element a such that, for all $x\in S$,

$$x = a \qquad \text{or} \qquad x - a \in P,$$

then strong restrictions are imposed upon the structure of A. In particular, if A is an infinite ring with identity e and if e is the least element of P, then A is isomorphic to the ring of integers.

2. Notations. Let $\mathbb{Z}$ denote the ring of integers with the usual addition and multiplication, and let $\mathbb{Z}^-$ denote the ring whose elements are the integers with the usual addition, but with the product $a \cdot b$ of two integers a and b equal to $-ab$, where ab is the usual product. Although $\mathbb{Z}$ and $\mathbb{Z}^-$ are isomorphic rings, they will be distinguished from each other. Let $\mathbb{Z}^\circ$ denote the ring whose elements are the integers with the usual addition, but with the product $a \cdot b$ of two integers a and b equal to zero, and let $\mathbb{Z}_k$, $\mathbb{Z}_k^-$ and $\mathbb{Z}_k^\circ$ denote respectively the subrings of $\mathbb{Z}$, $\mathbb{Z}^-$ and $\mathbb{Z}^\circ$ consisting of all integers mk, $m \in \mathbb{Z}$.

3. A characterization of the ring of integers. Throughout this section the ring A is supposed to consist of more than one element.

LEMMA 1. *A subset P of a ring A satisfies* (T) *if and only if the following two conditions hold*: (T_1) *The sum of any two elements of P is unequal to zero.* (T_2) *The sum of any two nonzero elements not belonging to P is unequal to zero.*

Proof. If P satisfies (T) then it is obvious that (T_1) and (T_2) hold.

Suppose conversely that (T_1) and (T_2) hold. By (T_1), $0 \notin P$ for otherwise $0+0 \neq 0$. Hence for each $a \in A$ at most one of the following holds: $a \in P$, $a=0$ or $-a \in P$. By (T_2), at least one of the following holds: $a \in P$, $a=0$ or $-a \in P$. Hence (T_1) and (T_2) imply (T).

LEMMA 2. *If a ring A has a subset P satisfying* (T), *then*:

(i) *Either A is infinite or A consists of an odd number of elements.*

(ii) *If A is finite, then for each $a \in P$, there exists $b \in P$ such that $a+b \notin P$. Consequently*

(iii) *if P contains an element a such that $a+b \in P$ for all $b \in P$, then A is infinite.*

Proof. (i) If A consists of an even number of elements, then there exists an element $a \neq 0$ such that $a=-a$, and hence $a \in P$ and $-a \in P$.

(ii) Since A is finite, there exists a least integer $m>1$ such that $ma=0$. Since $a \in P$, we have, by (T_1), $-a=(m-1)a \notin P$. Hence there exists a least positive integer $n \geqq 1$ such that $na \notin P$. Then $b=(n-1)a \in P$ is such that $a+b \notin P$.

The *converse* of the statement (ii) and (iii) of Lemma 2 is not necessarily true. This is shown by the following example.

Let P be the subset of $\mathbb{Z}$ consisting of all odd positive integers and all even negative integers. Then P satisfies (T), but for each $a \in P$ there exists $b \in P$ such that $a+b \notin P$.

LEMMA 3. *If a ring A has a subset P which satisfies* (T) *and* (W) *then the additive group of A is cyclic.*

Conversely, if the additive group of a ring A is cyclic and is infinite or consists of an odd number of elements, then there exists a subset P of A satisfying (T) *and* (W).

Proof. Let a be the least element of P. It will be shown that $A=\{ma: m\in Z\}$. Suppose this is false, and let U be the nonempty subset of A consisting of all elements of A which are not of the form ma. Then U contains elements of P, for $0\notin U$ and if $x\in U$, then $-x\in U$. Let b be the least element of U such that $b\in P$. Since $a=1a$, $b\neq a$ and hence $b-a\in P$. Since $b-(b-a)=a\in P$, we have $b-a\notin U$. It follows that $b-a=ma$ for some $m\in Z$, and therefore $b=(m+1)a$ which is a contradiction.

If the additive group of A is cyclic with the generator a and consists of the $(2n+1)$ elements $0, a, \cdots, 2na$, let P be the subset $\{ma: 1\leqq m\leqq n\}$ of A. Then P satisfies (T) and (W).

If the additive group of A is infinite and cyclic with the generator a, let P be the subset $\{ma: m\geqq 1\}$ of A. Then P satisfies (T) and (W).

THEOREM. *Suppose that a ring A has a subset P which satisfies* (T) *and* (W) *and let a be the least element of P.*

(i) *If $a^2=0$, then either A is isomorphic to any of the isomorphic rings Z_k° $(k=1, 2, \cdots)$ or A is isomorphic to a quotient ring $Z_k^\circ/Z_{k^2}^\circ$ for some positive integer k.*

(ii) *If $a^2\neq 0$, then there exist nonnegative integers h and k such that A is isomorphic to one of the rings Z_k/Z_{hk} or Z_k^-/Z_{hk}^-.*

Proof. (i) If $ka=0$ implies $k=0$, then the mapping $mk\to ma$ is an isomorphism from Z_k° onto A for all $k=1, 2, \cdots$; otherwise there exists a least positive integer k such that $ka=0$. The above mapping is then a homomorphism from Z_k° onto A with the kernel $Z_{k^2}^\circ$. Hence $A\cong Z_k^\circ/Z_{k^2}^\circ$.

(ii) There exists an integer k' such that $a^2=k'a$. Choose k' so that $|k'|=k$ is least. If k' is positive, then the mapping $mk\to ma$ is a homomorphism from Z_k onto A with the kernel Z_{hk}, where $h=0$ if A is infinite and h is the least positive integer such that $ha=0$ if A is finite. Hence $A\cong Z_k/Z_{hk}$.

If k' is negative, then the same mapping is a homomorphism from Z_k^- onto A such that $A\cong Z_k^-/Z_{hk}^-$.

COROLLARY. *If an infinite ring A with identity e has a subset P which satisfies the trichotomy condition* (T) *and the well-ordering condition* (W), *and if e is the least element of P, then A is isomorphic to the ring of integers.*

Proof. Z_k/Z_{hk} or Z_k^-/Z_{hk}^- has an identity element if and only if h and k are relatively prime. Since A is infinite, $h=0$ and hence $k=1$. That is, A is isomorphic to Z or Z^-. Since e is the least element of P, the mapping $m\to me$ is an isomorphism from Z onto A.

A NOTE ON REDUNDANCIES IN THE AXIOM SYSTEM FOR THE REAL NUMBERS

J. A. DYER, Iowa State University

Eves and Newsom in [1] have noted that in the usual axioms for a field the axiom of commutativity of addition is redundant. One can, however, give a perhaps simpler proof of this redundancy than that presented in [1]. This redundancy is in fact a consequence of the well-known result that a group G is Abelian if and only if the mapping, $\mathfrak{N}$: $G \to G$, defined by $\mathfrak{N}(x) = x^{-1}$, is an isomorphism.

It seems not, however, to have been noted by authors giving axioms for the real numbers, that in the axiom system for the real numbers, the commutative axioms for both addition and multiplication are redundant, if one extends the distributive axiom to include right distributivity of multiplication over addition. The purpose of this note is to outline a proof of this redundancy.

As an axiom system we take the following:

Suppose that R is a set, $+$ and $\cdot$ are mappings on $R \times R$ into R, and $<$ is a relation on R. The statement that $(R, +, \cdot, <)$ is a real number system means that

A1. $\exists 0 \in R$ such that $(R, +)$ is a group with 0 as identity.
A2. $\forall a, b, c \in R$, $a \cdot (b \cdot c) = (a \cdot b) \cdot c$.
A3. $\exists 1 \in R$ such that $1 \neq 0$ and $\forall a \in R - \{0\}$, $1 \cdot a = a$.
A4. $\forall a \in R - \{0\}$, $\exists a^{-1} \in R$ such that $a^{-1} \cdot a = 1$.
A5. $\forall a, b, c \in R$, $a \cdot (b + c) = (a \cdot b) + (a \cdot c)$ and $(a + b) \cdot c = (a \cdot c) + (b \cdot c)$.
A6. $<$ is a linear order on R such that $\forall a \in R$, $(a, a) \notin <$.
A7. $\forall a, b, c \in R$, $a < b \Rightarrow a + c < b + c$.
A8. $\forall a, b, c \in R$, $a < b$ and $0 < c \Rightarrow a \cdot c < b \cdot c$.
A9. Every subset of R which is bounded above has a least upper bound.

By standard techniques one can show:

THEOREM 1. $\forall a \in R$, $0 \cdot a = 0$.

THEOREM 2. $\forall a \in R$, $(-1) \cdot a = -a$.

As a consequence of Theorem 2 and A5 it follows that the mapping, $\mathfrak{N}: R \to R$, defined by $\mathfrak{N}(a) = -a$, $\forall a \in R$, is an isomorphism which implies:

THEOREM 3. $\forall a, b \in R$, $a + b = b + a$.

By the same proofs used in group theory one may show:

THEOREM 4. $\forall a \in R - \{0\}$, $a \cdot a^{-1} = 1$.

THEOREM 5. $\forall a \in R - \{0\}$, $a \cdot 1 = a$.

As an immediate consequence of Theorems 1 through 5 one has:

THEOREM 6. $\forall a \in R$, $a \cdot (-1) = -a$.

since a_n, $n=1, 2, 3, \cdots$, is rational, $a_n \cdot b = b \cdot a_n$, $n=1, 2, 3, \cdots$. Then, since R with the order topology is clearly a Hausdorff space, we obtain:

THEOREM 19. $\forall a, b \in R$, $a \cdot b = b \cdot a$.

Since A1 through A9 together with Theorems 3 and 19 constitute the usual axiom system for the real numbers, it follows that $(R, +, \cdot, <)$ is a real number system.

KEPLER'S SECOND LAW AND THE SPEED OF A PLANET

S. K. STEIN, University of California, Davis

As is well known, the farther a given planet is from the sun the slower it moves. (We shall call this the "speed property.") Sometimes Kepler's second law, which asserts that the radius vector from the sun to the planet sweeps out area at a constant rate, is cited as an explanation of the speed property. But this law, equivalent to the equation

$$\frac{1}{2}r^2 \frac{d\theta}{dt} = h, \qquad h \text{ constant}, \tag{1}$$

assures us that the farther the planet is from the sun, the smaller is its *angular speed* as viewed from the sun. On the other hand, the second law is also equivalent to the equation,

$$\frac{1}{2}p \frac{ds}{dt} = h, \qquad h \text{ constant}, \tag{2}$$

where $|ds/dt|$ is the speed of the planet at a typical point P and p is the distance from the sun to the tangent line to the orbit at P. Now (2) tells us that the farther the "instantaneous line of motion" of the planet is from the sun, the slower the planet moves. Thus neither (1) nor (2) immediately implies the speed property.

As we will show below, the speed property is *not* a consequence of the second law alone, but of that law together with a small part of the first law, which asserts that the orbit is an ellipse and the sun is at one focus. (What is needed is that the orbit is made up of congruent arcs.) The explanation, which makes use of the support function of a smooth plane convex curve, is summarized in Theorems 1 and 2. We will consider only convex curves that have a continuously turning tangent and only a finite number of normals through the pole of the coordinate system. We conclude with a remark on the physicist's explanation of the speed property in terms of energy.

since a_n, $n=1, 2, 3, \cdots$, is rational, $a_n \cdot b = b \cdot a_n$, $n=1, 2, 3, \cdots$. Then, since R with the order topology is clearly a Hausdorff space, we obtain:

THEOREM 19. $\forall a, b \in R$, $a \cdot b = b \cdot a$.

Since A1 through A9 together with Theorems 3 and 19 constitute the usual axiom system for the real numbers, it follows that $(R, +, \cdot, <)$ is a real number system.

KEPLER'S SECOND LAW AND THE SPEED OF A PLANET

S. K. STEIN, University of California, Davis

As is well known, the farther a given planet is from the sun the slower it moves. (We shall call this the "speed property.") Sometimes Kepler's second law, which asserts that the radius vector from the sun to the planet sweeps out area at a constant rate, is cited as an explanation of the speed property. But this law, equivalent to the equation

$$\frac{1}{2}r^2 \frac{d\theta}{dt} = h, \qquad h \text{ constant}, \tag{1}$$

assures us that the farther the planet is from the sun, the smaller is its *angular speed* as viewed from the sun. On the other hand, the second law is also equivalent to the equation,

$$\frac{1}{2}p \frac{ds}{dt} = h, \qquad h \text{ constant}, \tag{2}$$

where $|ds/dt|$ is the speed of the planet at a typical point P and p is the distance from the sun to the tangent line to the orbit at P. Now (2) tells us that the farther the "instantaneous line of motion" of the planet is from the sun, the slower the planet moves. Thus neither (1) nor (2) immediately implies the speed property.

As we will show below, the speed property is *not* a consequence of the second law alone, but of that law together with a small part of the first law, which asserts that the orbit is an ellipse and the sun is at one focus. (What is needed is that the orbit is made up of congruent arcs.) The explanation, which makes use of the support function of a smooth plane convex curve, is summarized in Theorems 1 and 2. We will consider only convex curves that have a continuously turning tangent and only a finite number of normals through the pole of the coordinate system. We conclude with a remark on the physicist's explanation of the speed property in terms of energy.

Consider a plane convex curve whose interior contains the origin of an xy-coordinate system, which coincides with the pole of the polar coordinate system whose polar axis is the positive x axis. The tangent line perpendicular to the ray of angle θ has the normal form

$$x \cos \theta + y \sin \theta = p(\theta).$$

The function p is the *support function* of the curve.

Now let the curve have the polar equation $r=f(\theta)$. The line $x \cos \theta+y \sin \theta = p(\theta)$ meets the curve at a unique point $(r^*, \theta^*) = (fh(\theta), h(\theta))$. It is known that

$$[p(\theta)]^2 + [p'(\theta)]^2 = (r^*)^2. \tag{3}$$

(To establish (3), note that the curve is the envelope of its tangent lines; hence (r^*, θ^*) is the intersection of $x \cos \theta+y \sin \theta=p$ and $x(-\sin \theta)+y \cos \theta=p'$.) In the proof of Theorem 2, where we refer to two convex curves, we will use the symbols $P(\phi)$, $R=F(\phi)$, ϕ^*, R^*, and H analogously.

THEOREM 1. *Let $r=f(\theta)$ describe a smooth convex curve and let α, β be two numbers such that $0 \leqq \alpha < \beta < 2\pi$. Assume that $f'(\alpha)=0=f'(\beta)$, and $f'(\theta) \neq 0$ for any θ in (α, β). Then not only is f monotonic for θ in $[\alpha, \beta]$, but so is the support function p.*

Proof. Let us assume that f is increasing for θ in $[\alpha, \beta]$. We will show that $p'(\theta)>0$ for θ in (α, β). Note that $p(\alpha)=f(\alpha)<f(\beta)=p(\beta)$. If $p'(\theta)=0$ then by (3) $fh(\theta)=p(\theta)$, whence $h(\theta)=\theta$ and $r^*=f(\theta)$. Thus the ray of angle θ is perpendicular to the curve at the point where it crosses the curve. Hence $f'(\theta)=0$, a contradiction. The theorem is proved.

The theorem assures us that on the arc stretching from a minimum of the function f to an (adjacent) maximum, not only f but also p is an increasing function. On this arc, therefore, the speed property holds: for the larger $f(\theta)$ is, the larger is $p(\theta)$, and, according to (2), the smaller is the speed of the planet.

If now we make use of Kepler's first law, then the speed property follows easily for the whole orbit. We may assume that the ellipse has the equation $r=f(\theta)=pe/(1+e \cos \theta)$. Hence f is increasing for θ in $[0, \pi]$. On this "top" arc Theorem 1 assures us that the speed property holds. Similarly the property holds on the "bottom" arc, corresponding to θ in $[\pi, 2\pi]$. Moreover, because of the congruence of these two arcs, at any two points on the ellipse that are equidistant from the sun, the tangent lines are also equidistant from the sun, hence by (2) the planet is moving at the same speed. This congruence is all we need from Kepler's first law, but, as the next theorem shows, it must be referred to. That is, the speed property is a consequence of Kepler's second law together with a certain geometric property of the orbit. Actually, it suffices that the ellipse is the union of a set of congruent arcs, each arc joining a minimum of f to an "adjacent" maximum linked in such a way that the union of two adjacent arcs is symmetric with respect to the line joining the sun to their common endpoint.

where C is a constant.

In view of (5) and (b) it follows that (a) is equivalent to the assertion "P depends only on the distance from the origin," or, equivalently, $\mathbf{F}=\nabla P$ is a central force; the assertion that $\mathbf{F}$ is a central force is a restatement of Kepler's second law. The speed property demands not only that P depend only on r but that it be a monotonically decreasing function of r.

Thus, in either approach Kepler's second law by itself does not imply the speed property.

ON THE DEFINITION OF EVEN AND ODD PERMUTATIONS

W. PHILLIPS, University of Colorado

Introduction. All of the usual definitions of even and odd permutations involve the polynomial $\prod_{i<j}(x_i-x_j)$ either as part of the definition (DEF: an even permutation is one that sends the polynomial $\prod_{i<j}(x_i-x_j)$ into itself) or in justifying the definition (DEF: an even permutation is one that can be written as the product of an even number of transpositions).

Of course there is nothing mathematically incorrect with either of these definitions, but students often find its use confusing as it seems to involve something totally irrelevant to the subject matter at hand, namely, permutations and permutation groups.

It is the purpose of this note to introduce an alternative to the above definitions. A proof is given (without the use of the above polynomial) that by this new definition an even permutation is, indeed, one that can be written as the product of an even number of transpositions. The definition and proof presuppose only the most basic knowledge of permutations, including the following elementary theorems:

THEOREM. *Any $x\in S_N$ can be written as the product of disjoint cycles. This decomposition is unique except for order.*

THEOREM. *The symbols appearing in a k-cycle may be permuted cyclicly without changing the permutation.*

THEOREM. *Any $x\in S_N$ $(N\geqq 2)$ can be written (in at least one way) as the product of transpositions.*

Even—Odd

DEFINITION. *Let $x\in S_N$. Define the (uniquely determined) integer $n(x)$ to be the number of cycles occurring in the unique decomposition of x into disjoint cycles including the 1-cycles.*

DEFINITION. *In S_N define a permutation x to be even or odd as the (uniquely determined) integer $N-n(x)$ is even or odd.*

where C is a constant.

In view of (5) and (b) it follows that (a) is equivalent to the assertion "P depends only on the distance from the origin," or, equivalently, $\mathbf{F}=\nabla P$ is a central force; the assertion that $\mathbf{F}$ is a central force is a restatement of Kepler's second law. The speed property demands not only that P depend only on r but that it be a monotonically decreasing function of r.

Thus, in either approach Kepler's second law by itself does not imply the speed property.

ON THE DEFINITION OF EVEN AND ODD PERMUTATIONS

W. PHILLIPS, University of Colorado

Introduction. All of the usual definitions of even and odd permutations involve the polynomial $\prod_{i<j}(x_i-x_j)$ either as part of the definition (DEF: an even permutation is one that sends the polynomial $\prod_{i<j}(x_i-x_j)$ into itself) or in justifying the definition (DEF: an even permutation is one that can be written as the product of an even number of transpositions).

Of course there is nothing mathematically incorrect with either of these definitions, but students often find its use confusing as it seems to involve something totally irrelevant to the subject matter at hand, namely, permutations and permutation groups.

It is the purpose of this note to introduce an alternative to the above definitions. A proof is given (without the use of the above polynomial) that by this new definition an even permutation is, indeed, one that can be written as the product of an even number of transpositions. The definition and proof presuppose only the most basic knowledge of permutations, including the following elementary theorems:

THEOREM. *Any $x\in S_N$ can be written as the product of disjoint cycles. This decomposition is unique except for order.*

THEOREM. *The symbols appearing in a k-cycle may be permuted cyclicly without changing the permutation.*

THEOREM. *Any $x\in S_N$ $(N\geqq 2)$ can be written (in at least one way) as the product of transpositions.*

Even—Odd

DEFINITION. *Let $x\in S_N$. Define the (uniquely determined) integer $n(x)$ to be the number of cycles occurring in the unique decomposition of x into disjoint cycles including the 1-cycles.*

DEFINITION. *In S_N define a permutation x to be even or odd as the (uniquely determined) integer $N-n(x)$ is even or odd.*

Proof. Write the permutation as a product of transpositions and starting from the *right* begin "collapsing" this expression by repeatedly multiplying the last two cycles together. At each step we have the product of a transposition and some other cycle. By the previous theorem the evenness or oddness always changes at each step however the evenness or oddness of the final result is fixed. Denying the conclusion, then, leads to a contradiction.

NOTE: From this point we can derive all the usual corollaries, for example:

COROLLARY. *The product of two permutations is even if either both are even or both odd. Otherwise the product is odd.*

MATHEMATICAL EDUCATION NOTES

THE DITCHLEY CONFERENCE SCHOOL MATHEMATICS OF TWO COUNTRIES

E. L. LOMON, Massachusetts Institute of Technology and C.C.S.M.

The first wave of mathematics curriculum reform has crested in both the United Kingdom and the United States. Those initial efforts were sensitive to the traditional curriculum, school organization and teacher preparation of each country. New curricula had to be separately tested on a small scale before being committed to large scale use within each country. Until these results were seen, it was unlikely that either party could help the other significantly. Published texts and reports allowed the monitoring of the ideas and progress of the other party. Now that both countries have had experience on a wide scale with the "new math," a second wave of new curricula is forming. At this stage it seems appropriate to capitalize on the corroborative, contradictory or complementary experience of the two countries.

The initiative was taken by Professor Bryan Thwaites and Professor W. T. Martin. The former is director of the School Mathematics Project (SMP), the most extensive project of its type in England. The latter is Chairman of the Cambridge Conference on School Mathematics (CCSM). SMP undertook to invite the U.K. delegation and to obtain the conference facilities. The American delegates were invited by CCSM, using a Carnegie Corporation grant and NSF funds. The excellent representation of major curriculum projects indicates the interest aroused in both countries by the topic. The participants are listed at the end of this article.

THE DITCHLEY CONFERENCE SCHOOL MATHEMATICS OF TWO COUNTRIES

E. L. LOMON, Massachusetts Institute of Technology and C.C.S.M.

The first wave of mathematics curriculum reform has crested in both the United Kingdom and the United States. Those initial efforts were sensitive to the traditional curriculum, school organization and teacher preparation of each country. New curricula had to be separately tested on a small scale before being committed to large scale use within each country. Until these results were seen, it was unlikely that either party could help the other significantly. Published texts and reports allowed the monitoring of the ideas and progress of the other party. Now that both countries have had experience on a wide scale with the "new math," a second wave of new curricula is forming. At this stage it seems appropriate to capitalize on the corroborative, contradictory or complementary experience of the two countries.

The initiative was taken by Professor Bryan Thwaites and Professor W. T. Martin. The former is director of the School Mathematics Project (SMP), the most extensive project of its type in England. The latter is Chairman of the Cambridge Conference on School Mathematics (CCSM). SMP undertook to invite the U.K. delegation and to obtain the conference facilities. The American delegates were invited by CCSM, using a Carnegie Corporation grant and NSF funds. The excellent representation of major curriculum projects indicates the interest aroused in both countries by the topic. The participants are listed at the end of this article.

The meeting was held September 9–11, 1966, at Ditchley Park Estate, Oxfordshire, operated as an "Anglo-American Conference Centre." This note relates my personal impressions. A report for distribution in the U.K. has been prepared by Professor Thwaites.

Professor Thwaites and Professor Martin, the co-chairmen, skillfully preserved a relaxed atmosphere. The topics of the plenary and group sessions are appended. I shall make no attempt to relate my remarks to particular sessions.

In order to profit from the different curriculum histories in the two countries the conferees were alert to variations of accomplishment and attitude. A difference affecting the whole of the secondary school programs is in the amount of integration of geometry with algebra or analysis. SMSG and other widely used new American texts largely maintain the traditional separation of these materials, with exceptions, as in the presentation of such topics as graphing. In the texts of SMP and of the Midlands Mathematical Experiment, these subjects are interlaced in each term, with frequent cross-referencing. A related divergence is the larger degree of systematization and formality in the American courses. Historical reasons for these differences are discernible, but it is more interesting to enquire about the present reactions and future intentions of the two groups.

I digress here to make a point that I believe essential. There is a wide divergence of attitudes among those active in curriculum development on each side of the Atlantic. The spread of opinion on either side is greater than the difference of the average opinion between the two countries. Any opinion or attitude concerning school mathematics that has substantial support in one country will have important advocates in the other. Present differences of substance are mostly due to the pressure of historical and accidental circumstance. The actual diversity of opinion of the U.S. is well known to many. The meeting displayed a similar diversity among the initiators of curriculum reform in the U.K.

The existence of reform curricula in both countries has effected a separation from the historical requirements. This allows the succeeding reforms in each country to approach a common result. In my opinion the major circumstance causing the present difference of emphasis in the two countries is the relative brevity of experience in the U.K. with new mathematics in the elementary school. The first large scale elementary school project was introduced only last September, by the Nuffield Mathematics Project. This project is sophisticated, and well in advance of the first such American attempts. Its impact, however, has not yet been felt. For most of the British curriculum developers, this leaves the early secondary school mathematics as the beginning of the "spiral" of mathematics ideas and applications. An intuitive approach at this level is thus prescribed. The dominantly intuitive development of many topics is now expected by Americans to take place in elementary school. It follows naturally that a larger degree of systematization and deductive reasoning is planned for secondary school courses. I would expect a similar evolution in the U.K. to take place between the coming revision and the one succeeding it.

On the other hand, the impact of the first reform has made the American schools more flexible with respect to the organization of topics. The U.S. projects will probably take the next opportunity to use several specific effective examples, developed in the U.K. and here, of combining geometric and algebraic material.

An important example of complementary curriculum investigations exists in the experience of each country with motion (or transformation) geometry. The SMP program uses symmetry as the organizing principle for much of its geometry. We can here observe on a large scale the efficacy of the approach in the context of a related program. In the U.S. the experiments have been directed towards finding an effective intuitional development of symmetry motions in elementary school, developing through the junior high school into a systematic basis for geometry and modern algebra in high school. These experiments have been on a small scale, and not in the context of a related mathematics course. The U.K. experience can be taken as strong encouragement for the large scale development of the American materials.

One of the claims most often made for the "new math" is that it teaches unifying concepts which help the student generalize and transfer from one problem to another. The introduction of "sets" at an early primary grade is usually justified in that way. It is thus salutary that delegates from both countries felt that we are only coming to grips with a unifying language and imagery. The role of "set theory" or "functions" in concisely stating the structure of different branches of mathematics was said to require more experience and sophistication in mathematics than the student would have through his school years. A corollary is that the introduction of such topics as sets and functions must avoid being pretentious or formal. There was more hope and intention among Americans than among Britons that the improvement of the curriculum would eventually permit some revelation of structurally unifying significance of concepts.

Both groups stressed the importance of developing and continually presenting good applications of the mathematical ideas and tools. The best applications use the appropriate mathematics to study situations of importance. They elucidate the modeling process, giving the student the power to devise his own applications. In both countries collections of good applications have been made.

Good applications tend to go deeply into the field of the application, so that more than the mathematics curriculum is involved. In this country we are beginning explorations of the correlation of the mathematics with the science curricula. The absence of science material in the U.K. elementary schools has left the matter of correlation less urgent.

In the light of the need for good applications, the teaching of some probability and a little statistics is very appealing. All of arithmetic is applied in obtaining distributions from data, and in calculating theoretical distributions. The mathematics of probability is in turn applied to problems in almost every scientific and sociological endeavour. Experimental probability can be introduced in the earliest years, and the theory developed as facility with sets, alge-

bra and analysis is successively developed. The subject shows what so few laymen realize, that mathematics can deal with imprecise information and indeterminate models. I expect that probability and perhaps statistics will soon have a major role in the curricula of both countries.

In present practice, the British give more emphasis to cardinal numbers and discrete algebraic systems, and in the United States there has been a tendency to develop the concept of real numbers at an early stage, and later treat fields and analysis. Present opinions in both countries are widely divergent.

The program of the conference directed us to discuss matters of teaching style and method, as well as content. It is perhaps surprising that the U.K. emphasis on informality in the presentation of mathematics is not correlated with strong emphasis on an "open-ended discovery" classroom approach. We viewed a film in which a deeply involved Madison Project class was purposefully nondirected by Professor Robert Davis. Most, if not all, of the British present felt that the students could not extract useful results from the emotional discussion, or they questioned that the usual teacher could handle the situation. Lest one is still tempted to oversimplify the contrast of U.S. and U.K. attitudes, it should be noted that Professor Davis has an interest in the teaching of axiomatic structures and some level of logic to the very young!

Consideration was given to the results of behavioral science and learning studies of psychologists. In both countries there have been only minor attempts at devising curricula oriented about approaches suggested by these studies. Their results on perception and mental skills at different ages have been interpreted as indicating important but not insurmountable obstacles to the goals of the mathematics curriculum. The major programs in both countries take the findings of psychologists into account by, for instance, a careful development of spatial perception at the age they think it relevant. A more direct reaction to those findings would be to ignore specific types of perception until they develop "naturally." Very little curriculum development has been based on the latter reaction.

Professor A. Gleason suggested a direct use of the educational process that is perhaps best understood—the conditioned reflex. There are many good reasons to concentrate on more interesting mathematics in elementary school than the traditional arithmetic drill. Professor E. Begle had reported on a very satisfying SMSG experiment in which seventh grade children behind grade level in computation were relieved of all computation for a year. At the end of the year they had, on the average, gained two and a half years in arithmetic reasoning and also one and a half years in computation! But there will be children who are poor computers at the end of several grades of stimulating mathematical ideas, just as there are at the end of several grades of boring drill. Professor Gleason pointed out that the skill of the behavioral scientist at inculcating responses may provide a comparatively painless and rapid way of remedying the situation for these children.

The effect of technical revolutions on the teaching of mathematics received

much attention. The British delegates were impressed by the appearance of computer consoles in many American secondary schools. Although there was little enthusiasm for courses in programming as such, integrated use of a computer in the mathematical course had wide appeal. Many advantages of the availability of a computer were cited. In problem solving additional insight would be given into the procedure of solution, even for analytically soluble problems. Applications could be introduced, for which the comparison of computed numbers with measured numbers would not have otherwise been possible. The programming itself was regarded as a training in careful, precise thought, and in logic. On another level the use of a computer provides motivation to the student, confidence through checking and a release from boring computation.

The reaction was very different when attention was directed towards computers as teaching machines; that is, programmed to teach the student rather than programmed by the student. The expectation was expressed that the programming of sufficiently flexible and subtle teaching would be a formidable task. Very costly investments would be required in the highly competitive computer industry. It was feared that the resultant industry pressure may lead to early adoption preceding the proper development and testing of teaching programs. This would leave schools with the burden of expensive and perhaps harmful computer-based teaching machines.

The recommendation was that the mathematical community should devote serious study to computer-based instruction with the object of producing an acceptable product or at least of being an effective critic. The British felt that there was little immediate danger of funds being available in their country for an over-commitment.

The need for large scale testing was a matter of concern to the British. This is needed in the relative evaluation of curricula (as in the National Longitudinal Study of Mathematical Abilities of SMSG) if not for the grading of increasing numbers of students. Professor R. P. Dilworth presented impressive evidence of the reliability of carefully prepared objective machine-scored tests. It would appear that they are more reliable predictors (of something!) than the conventional "essay type" responses that require careful reading. As Dilworth pointed out, an advantage of large scale machine-scored testing is the possibility of statistically analyzing pretests. The modified test prepared on this basis contains a higher percentage of meaningful questions. The British expressed the desire for the help of American testing experts in devising tests of their own.

The growing exchange of information between the resulting curriculum development in both countries will tend to bring them closer together. However, differences in organization and attitude, noted at the conference, will condition the relative direction of progress for some time to come. There is an existing difference in the standards for teachers (masters) and in the content of their training. Standards are more uniform in the U.K. and on the high side of the U.S. levels. The smaller percentage of college bound students in the U.K. will be a factor in determining the content of secondary school instruction. The

presence in the USSR of schools specializing in mathematics or science was discussed and the few American parallels noted. This has impact on only a small part of the student population. In the U.K. some specialization takes place in secondary schools prior to college entrance, as it does in differing forms in the United States.

I detected a difference of attitude that may lead to long term differences in the curricula of the two countries. The American attitude is dominantly (remember the individual diversity!) that some ability to use the subtler mathematical ideas associated with symmetry, continuity, probability, and modelling should be widely diffused through the population. In the U.K. the desire is, it seems to me, to present these more esoteric topics to the general population only at the conceptual level, reserving any formal command for the more "practical" skills. Calculus, for example, is considered relevant only for students going on to be scientists, engineers or mathematicians. There is clearly a division on this issue in this country, and this is not the place to present the arguments for either approach. But the next "wave" here is likely to present a program designed to enable the bulk of the population to make some headway in modelling and analyzing real situations involving, for instance, probability. In the U.K. the more formal material may be designed for the smaller population that is specially motivated and able.

The direction of the reform movements may also be affected by the relatively smaller participation of university mathematicians in the U.K. In the U.S.A., university mathematicians direct curriculum development groups, are on the textbook writing teams, and are occasionally in the experimental classrooms. It was noted that some internationally known Soviet mathematicians teach classes of young children on a regular basis. In the U.K. the university participation has mostly been on the level of general formulation and advice. The writing, directing and participation in experimental work is by schoolmasters, some of whom have been on University faculties. There is a handful of active research mathematicians participating actively in the curriculum reform.

Most of the American delegates arrived at the conference knowing little of the scope of U.K. accomplishments and intentions in mathematics curriculum reform. It is my impression that on the whole the U.K. contingent was better informed of American accomplishments, but as poorly informed of the present direction of our thinking and effort as we were of theirs. Only a few delegates from either country had previously had sufficient contacts, such as in the African Program, to reveal their orientation to each other.

On leaving we felt that we had only scratched the surface. The Americans had learned of the important scale on which new and very enjoyable courses have been introduced in the U.K. We had become familiar with the organizations and some of the key people involved. Their special interests and their publications are now largely known to us. This is a critical first step in being able to gather further information by correspondence and in looking forward to working contacts. Effective liaison may expand rapidly from this beginning.

SOME REMARKS ON "A DILEMMA IN DEFINITION"

R. B. DEAL, Oklahoma State University

These comments were conceived in preparation for a discussion of the article "A Dilemma in Definition" by C. P. Nicholas, U. S. Military Academy, in this MONTHLY, Volume 73, number 7, scheduled for one of the pedagogical discussion periods in the seminar for graduate teaching assistants at Oklahoma State University.

Mr. Nicholas discusses ambiguities and concomitant student frustrations arising from some of the current attempts to define functions and to distinguish between functions and function values. The points are important, and his criticism merits serious consideration.

It should first be remarked that this is one of a variety of related problems which makes teachers necessary. Mathematics teachers should make the meaning of definitions and theorems intuitively clear. They must distinguish between the informal intuitionistic plausible procedures often used to develop mathematical results and the strictly logical processes with precise definitions which insure the validity of their conclusions.

The fundamental basis for mathematical structures today is that of "naive" set theory. It is simply a matter of experience that being able to go back to these fundamental structures is a safeguard in case of ambiguities or difficulties in understanding. It is just as foolhardy to assume that such a return to basic principles is always necessary as to insist that in doing arithmetic with integers one always should return to Peano's postulates.

The old calculus books were replete with examples where difficulty in understanding arose from a lack of adequate definitions. There would seem to be little point in a return to one of these concepts, namely, "variable," especially since a good understanding of functions and their compositions is so important to the understanding of limits, derivatives, integrals, and the chain rule.

The recent widespread use of categories as a synthesizing concept in mathematics illustrates very well the importance of emphasizing the domain and range, as well as the procedure for assigning to each member in the domain an

element in the range, and the basic properties of composition of functions.

After having taught the "classical" calculus many times several years ago, it was a pleasant surprise last year to find that many of the modern innovations add considerably to depth of understanding. It is not difficult to impress upon one's students that whatever formal definition is used for function, it must be such that the domain is specified, a range is specified, and that to each element in the domain there is assigned one and only one element of the range. Furthermore, it is easy to see that giving a definition as a subset of a Cartesian product of sets is an easy way of accomplishing this purpose. Just as one uses theorems to build further mathematical structures instead of always reverting to axioms, one uses the properties of functions, once they have been established, instead of always reverting to the definition.

The simple device of

$$f: \begin{cases} A \to B \\ x \to f(x) \end{cases}$$

avoids many ambiguities and in making notes for a calculus class it was found that often only function values were used in a discussion and it was not necessary to mention the functions per se.

It seems that there should be no difficulty with good definitions in referring to real-valued functions on some subset of the reals as being increasing or decreasing. It may be important to have this concept independent of the physical idea of the point moving up or down. From a sound modern point of view on the "scientific method" it is necessary to have available in the mathematical models a definition of function in order to express the physical concept of variable or the statistical concept of random variable.

As for the function f: $x \to \log \sin x$, it is important to specify the domain. In elementary calculus, this must be a subset of $\{x \mid \exists k \in Z \ni 0 < x - 2k\pi < \pi\}$ where Z is the set of integers. This point is also worth laboring.

It is quite likely that in 1905 a sound argument could have been made that the horse could do everything a car could, and better, and without all the expense of building special trails. A transition to better concepts should not be influenced by a few mistakes along the way.

A REPLY TO "A DILEMMA IN DEFINITION"

H. A. THURSTON, University of British Columbia

C. P. Nicholas' [1] first sentence is true: many text-books of calculus do place the student in a quandary over the word "function." But his third sentence—"The result is an ambiguity which even the most careful writers are unable to avoid"—is false. The most careful writers can and do avoid it. Would that more of them (or, rather, fewer of the others) wrote calculus texts!

Part of Mr. Nicholas' trouble is this: the logical analysis of a familiar and

element in the range, and the basic properties of composition of functions.

After having taught the "classical" calculus many times several years ago, it was a pleasant surprise last year to find that many of the modern innovations add considerably to depth of understanding. It is not difficult to impress upon one's students that whatever formal definition is used for function, it must be such that the domain is specified, a range is specified, and that to each element in the domain there is assigned one and only one element of the range. Furthermore, it is easy to see that giving a definition as a subset of a Cartesian product of sets is an easy way of accomplishing this purpose. Just as one uses theorems to build further mathematical structures instead of always reverting to axioms, one uses the properties of functions, once they have been established, instead of always reverting to the definition.

The simple device of

$$f: \begin{cases} A \to B \\ x \to f(x) \end{cases}$$

avoids many ambiguities and in making notes for a calculus class it was found that often only function values were used in a discussion and it was not necessary to mention the functions per se.

It seems that there should be no difficulty with good definitions in referring to real-valued functions on some subset of the reals as being increasing or decreasing. It may be important to have this concept independent of the physical idea of the point moving up or down. From a sound modern point of view on the "scientific method" it is necessary to have available in the mathematical models a definition of function in order to express the physical concept of variable or the statistical concept of random variable.

As for the function f: $x \to \log \sin x$, it is important to specify the domain. In elementary calculus, this must be a subset of $\{x \mid \exists k \in Z \ni 0 < x - 2k\pi < \pi\}$ where Z is the set of integers. This point is also worth laboring.

It is quite likely that in 1905 a sound argument could have been made that the horse could do everything a car could, and better, and without all the expense of building special trails. A transition to better concepts should not be influenced by a few mistakes along the way.

H. A. THURSTON, University of British Columbia

C. P. Nicholas' [1] first sentence is true: many text-books of calculus do place the student in a quandary over the word "function." But his third sentence—"The result is an ambiguity which even the most careful writers are unable to avoid"—is false. The most careful writers can and do avoid it. Would that more of them (or, rather, fewer of the others) wrote calculus texts!

Part of Mr. Nicholas' trouble is this: the logical analysis of a familiar and

and 3, $2\times3=3\times2$." This is because they are not merely numerical variables; they are *bound* numerical variables.) In the preceding paragraph, τ, τ_1, and τ_2 are numerical variables.

It is not rare for a word to be used differently in different branches of mathematics (for example: "normal" in solid geometry and in the theory of groups). The different uses of "variable" in physics and practical calculus on the one hand and in mathematical logic on the other should give no trouble, but unfortunately these topics overlap in elementary analysis (or "text-book calculus") where the two concepts are sometimes confused. One certain cure for the confusion is to use separate alphabets, just as in this note I have used the Roman alphabet for "variable quantities" or "function variables" and the Greek alphabet for "pro-numerals" or "numerical variables." On this convention it is quite clear that x^2 and $\sin x$ denote functions, whereas ξ^2 and $\sin \xi$ do not. Without it, one has to know what x denotes: if x denotes a function, then x^2 denotes a function; if x denotes a number, then x^2 denotes a number.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, University of Massachusetts; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N.J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before April 30, 1968. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.

E 2035. *Proposed by Stanley Rabinowitz, Far Rockaway, N. Y.*

Can the Euler line of a nonisosceles triangle pass through the Fermat point

and 3, $2\times3=3\times2$." This is because they are not merely numerical variables; they are *bound* numerical variables.) In the preceding paragraph, τ, τ_1, and τ_2 are numerical variables.

It is not rare for a word to be used differently in different branches of mathematics (for example: "normal" in solid geometry and in the theory of groups). ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before April 30, 1968. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.

E 2035. *Proposed by Stanley Rabinowitz, Far Rockaway, N. Y.*

Can the Euler line of a nonisosceles triangle pass through the Fermat point

SOLUTIONS OF ELEMENTARY PROBLEMS

Conditions for a Real Inequality

E 1885 [1966, 537]. *Proposed by D. E. Daykin and C. J. Eliezer, University of Malaya, Kuala Lumpur*

For which continuous functions $f(x)$ do we have

$$a_1^{f(a_1)}\, a_2^{f(a_2)} \cdots a_n^{f(a_n)} \geqq 1, \tag{1}$$

for all positive real numbers $a_1, \cdots, a_n$ with product $a_1a_2 \cdots a_n = 1$?

Solution by the proposers. The inequality holds if and only if

$$f(a) \leqq f(1) \leqq f(b) \qquad \text{for } 0 < a \leqq 1 \leqq b. \tag{2}$$

Since

$$a_1^{f(a_1)} \cdots a_n^{f(a_n)} = (a_1^{f(a_1)-f(1)}) \cdots (a_n^{f(a_n)-f(1)}),$$

(1) is true and the condition is sufficient. To see that it is necessary, let (1) be given and let $a \leqq 1 \leqq b$. Then there are α, β as close as we like to a, b, respectively, such that $1 < \beta$ and $\alpha^r\beta^s = 1$ for positive integers r, s. Let $n = r+s$ and $a_1 = \cdots = a_r = \alpha$ and $a_{r+1} = \cdots = a_n = \beta$. Then

$$1 \leqq a_1^{f(a_1)} \cdots a_n^{f(a_n)} = \alpha^{rf(\alpha)}\beta^{sf(\beta)} = \beta^{s(f(\beta)-f(\alpha))},$$

so that $f(\alpha) \leqq f(\beta)$, and by continuity of $f(x)$ we have $f(a) \leqq f(b)$ giving (2).

Also solved by P. R. Chernoff, M. A. Ettrick, G. A. Heuer, E. S. Langford, and Jürg Rätz (Switzerland).

Special Quadrics

E 1886 [1966, 538]. *Proposed by W. M. Sanders, Lawrence University, Appleton, Wis.*

Show that if $ax^2+by^2+cz^2+2fxy+2gzx+2hyz+2rx+2sy+2tz+d=0$ represents two distinct planes, then the matrix

$$E = \begin{pmatrix} a & f & g & r \\ f & b & h & s \\ g & h & c & t \\ r & s & t & d \end{pmatrix}$$

is not the adjoint of any matrix.

I. *Solution by Yu Chang and Sidney Spital, California State Polytechnic College.* The conclusion is true also for cones (real or imaginary) and cylinders (elliptic, hyperbolic or parabolic). A proof uses the following theorems applied to 4×4 matrices:

SOLUTIONS OF ELEMENTARY PROBLEMS

Conditions for a Real Inequality

E 1885 [1966, 537]. *Proposed by D. E. Daykin and C. J. Eliezer, University of Malaya, Kuala Lumpur*

For which continuous functions $f(x)$ do we have

so that $f(\alpha) \leqq f(\beta)$, and by continuity of $f(x)$ we have $f(a) \leqq f(b)$ giving (2).

Also solved by P. R. Chernoff, M. A. Ettrick, G. A. Heuer, E. S. Langford, and Jürg Rätz (Switzerland).

Special Quadrics

E 1886 [1966, 538]. *Proposed by W. M. Sanders, Lawrence University, Appleton, Wis.*

Show that if $ax^2+by^2+cz^2+2fxy+2gzx+2hyz+2rx+2sy+2tz+d=0$ represents two distinct planes, then the matrix

$$E = \begin{pmatrix} a & f & g & r \\ f & b & h & s \\ g & h & c & t \\ r & s & t & d \end{pmatrix}$$

is not the adjoint of any matrix.

I. *Solution by Yu Chang and Sidney Spital, California State Polytechnic College.* The conclusion is true also for cones (real or imaginary) and cylinders (elliptic, hyperbolic or parabolic). A proof uses the following theorems applied to 4×4 matrices:

where D is diagonal, nonsingular, and at least 2×2. Since E is singular, it follows that $EA=AE=$ the zero matrix, so that A must be of the following form:

$$A=\left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & X \end{array}\right).$$

If we now compute A^*, we see that the northwest corner is at least 2×2, so that the cofactors A_{11} and A_{22} are both zero. This contradicts the fact that D is nonsingular.

Also solved by M. G. Greening (Australia).

Sums of 2^p Squares

E 1889 [1966, 538]. *Proposed by Joseph Arkin, Suffern, New York*

Prove: The sum of 2^p squares $(\sum_{j=1}^{2^p} y_j^2)$ can always be expressed (in an infinite number of ways) as the quotient $(\sum_{j=1}^{2^p} A_j^2/\sum_{j=1}^{2^p} x_j^2)$ of two numbers, each of which is a sum of 2^p squares $(p=0, 1, 2, \cdots)$.

Solution by Leon Bankoff, Los Angeles, Cal. The following proof is for a more general proposition in which 2^p is replaced by any positive integer n.

Starting with any Pythagorean triangle, we may construct a succession of other Pythagorean triangles, each having an arm on the hypotenuse of its predecessor. (See W. Sierpinski, *Pythagorean Triangles*, Yeshiva University, N. Y., 1962, p. 26). Hence there exist an infinite number of squares of natural numbers that can be expressed as the sum of any finite number of other squares.

Now let $k^2=x_1^2+\cdots+x_n^2$. Then there are an infinite number of solutions of

$$k^2\left(\sum_{j=1}^{n} y_j^2\right)=\sum_{j=1}^{n} k^2y_j^2=\sum_{j=1}^{n} A_j^2.$$

Also solved by Anders Bager (Denmark), G. A. Heuer, E. S. Langford & E. B. Keeler' Norman Miller, D. L. Silverman, Sidney Spital, and the proposer.

Editorial Note. Some of our readers tried to show that the product of two sums of 2^p squares can always be written as the sum of 2^p squares. This is indeed true for $p=1, 2, 3$, but not for $p>3$. This was first proved by A. Hurwitz. For references and a detailed discussion see a paper by Dickson: *On quaternions and their generalization and the history of the eight square theorem.* Ann. Math., 20 (1919) 155–171.

A Sequence of Square Roots

E 1890 [1966, 538]. *Proposed by Emanuel Vegh, Naval Research Laboratory*

If m and n are given integers greater than one, show that there exist positive integers $N_1, N_2, \cdots, N_{m-1}$ such that

$$\sqrt{m}=1+\sum_{i=1}^{m-1}(\sqrt{N_i}-\sqrt{N_i-1})^{1/n}.$$

Solution by Anders Bager, Hjørring, Denmark. Let i be one of the numbers $1, 2, \cdots, m-1$. By the binomial theorem:

$$(\sqrt{i+1} \pm \sqrt{i})^n = x_i \pm y_i\sqrt{i(i+1)},$$
$$(\sqrt{i+1} \pm \sqrt{i})^n = u_i\sqrt{i+1} \pm v_i\sqrt{i},$$

according as n is even or odd, respectively. In both cases we therefore have two equations:

$$(\sqrt{i+1} + \sqrt{i})^n = \sqrt{N_i} + \sqrt{M_i}, \tag{1}$$

$$(\sqrt{i+1} - \sqrt{i})^n = \sqrt{N_i} - \sqrt{M_i}. \tag{2}$$

By multiplication of (1) and (2) we get $1 = N_i - M_i$, so that

$$\sqrt{i+1} - \sqrt{i} = (\sqrt{N_i} - \sqrt{N_i - 1})^{1/n}. \tag{3}$$

Summing (3) through all values of i we get the desired formula.

Also solved by Robert Bart, N. J. Fine, Donald Jeffords, Carey Jensen, E. S. Langford, D. C. B. Marsh, Norman Miller, Wanda J. Mourant, Jürg Rätz (Switzerland), and Simeon Reich (Israel).

Multiplicative Function

E 1891 [1966, 538]. *Proposed by A. E. Livingston, Oregon State University*

Let f be a number-theoretic function, and set

$$F(n) = \sum_{d|n} f(d) f\left(\frac{n}{d}\right).$$

If $f(1) = 1$, and F is multiplicative, then f is multiplicative.

I. *Solution by D. A. Smith, Duke University.* We prove $f(mn) = f(m)f(n)$ for $(m, n) = 1$ by induction on mn. For $mn = 1$, this is clear. Write

$$F(mn) = \sum_{d|mn} f(d) f\left(\frac{mn}{d}\right) = 2f(mn) + \sum_{\substack{d|mn \\ d \neq 1, mn}} f(d) f\left(\frac{mn}{d}\right). \tag{1}$$

By hypothesis, this is also equal to

$$\begin{aligned} F(m)F(n) &= \left[\sum_{d_1|m} f(d_1) f\left(\frac{m}{d_1}\right)\right]\left[\sum_{d_2|n} f(d_2) f\left(\frac{n}{d_2}\right)\right] \\ &= \sum_{\substack{d_1|m \\ d_2|n}} f(d_1) f(d_2) f\left(\frac{m}{d_1}\right) f\left(\frac{n}{d_2}\right). \end{aligned} \tag{2}$$

We have $(d_1, d_2) = 1$ and $(m/d_1, n/d_2) = 1$ for each term, so the induction hypothesis applies to all terms in the sum except the first and last, hence (2) can

be rewritten

$$F(m)F(n) = 2f(m)f(n) + \sum f(d_1d_2)f\left(\frac{mn}{d_1d_2}\right), \tag{3}$$

where the sum is over pairs $d_1 \mid m$, $d_2 \mid n$ such that $d_1d_2 \neq 1$, mn. If we set $d = d_1d_2$, again using $(m, n) = 1$, the sum in (3) is the same as the sum in (1), and it follows that $f(mn) = f(m)f(n)$, completing the induction step.

II. *Solution by Sidney Spital, California State Polytechnic College.* Inversion via the Moebius function yields

$$f(1)f(n) = \sum_{d \mid n} \mu(d)F(n/d).$$

With μ and F multiplicative (and $f(1) = 1$), it is easily seen that f is also multiplicative.

Also solved by Anders Bager (Denmark), P. R. Chernoff, M. G. Greening (Australia), Donald Jeffords, E. S. Langford, Al Somayajulu, C. S. Venkataraman (India), and M. M. Whiteside.

A Generalized Coupon Collector's Problem

E 1892 [1966, 539]. *Proposed by Melvin Hausner and Paul Magriel, New York University*

An experiment has n possible outcomes σ_i, each with probability $p_i > 0$, $\sum p_i = 1$. The experiment is repeated as many times (N) as necessary until every outcome has occurred. What is the expected value of N?

Solution by P. J. Burke, Middletown, N. J. Let σ_{i_j} be the jth outcome to appear and let $E_{i_1 \cdots i_m}$ be the event that the first m outcomes to appear are $\sigma_{i_1}, \cdots, \sigma_{i_m}$. Let N_m be the number of trials between the first appearance of σ_{i_m} and that of $\sigma_{i_{m+1}}$, inclusive of the latter. Then, since σ_{i_1} always appears on the first trial, $N = 1 + \sum_{m=1}^{n-1} N_m$. Define

$$q_{i_1 \cdots i_m} = 1 - (p_{i_1} + \cdots + p_{i_m}).$$

Then the probability of $E_{i_1 \cdots i_m}$ is

$$p_{i_1} \frac{p_{i_2}}{q_{i_1}} \cdots \frac{p_{i_m}}{q_{i_1 \cdots i_{m-1}}}.$$

The conditional expectation of N_m given $E_{i_1 \cdots i_m}$ is $1/q_{i_1 \cdots i_m}$. Hence the expectation of N_m is

$$S_m = \sum_{i_1 \neq \cdots \neq i_m} \frac{p_{i_1} \cdots p_{i_m}}{q_{i_1} \cdots q_{i_1 \cdots i_m}},$$

and the expectation of N is $1 + \sum_{m=1}^{n-1} S_m$.

Also solved by Shirley Braverman & P. A. Scheinok, P. R. Chernoff, E. S. Keeping, and E. S. Langford.

Several noted that the present problem is a direct generalization of one in Feller, *Probability Theory*, v. I, pp. 210–211.

Functions for which $f^{-1} = 1/f$

E 1894 [1966, 539]. *Proposed by K. E. Whipple, Auburn University*

Characterize those real valued functions, continuous everywhere except zero, for which $f^{-1} = 1/f$.

Solution by F. G. Gustavson, IBM, Yorktown Heights, N. Y. The functions f are characterized by the following properties:

(a) $f(x)f(1/x) = 1$, (b) $f(1) = -1$,
(c) $f(x)$ is monotonic in $(0, 1)$ (d) $\lim_{x\to 0+} f(x) = 0$ or $-\infty$,
(e) $f(x)$ is defined in $(-\infty, 0)$ by reflection of $1/f(x)$ on $(0, \infty)$ in the line $y = x$.

Example:

$$f(x) = \begin{cases} -1/x & x < 0 \\ -x & x \geqq 0. \end{cases}$$

Proof: (a) From $f^{-1}(f(x)) \equiv x$ and $f^{-1}(x) = 1/f(x)$ we find $f(f(x)) = 1/x$. Thus $f(x) = f^{-1}(1/x) = 1/f(1/x)$ or $f(x)f(1/x) = 1$.

(b) Put $x = 1$ in (a) and find $f(1) = \pm 1$. If $f(1) = 1$, then no function f exists, for f and f^{-1} have the same monotonicity property in a neighborhood of $x = 1$ while $1/f$ has the opposite property.

(c) If $f(x)$ were not monotonic in $(0, 1)$, then $f^{-1}(x)$ would not be single-valued for all negative x.

(d) Suppose that $f(x)$ is monotonic increasing in $(0, 1)$. Then if $\lim_{x\to 0+} f(x) \neq -\infty$, we have $\lim_{x\to 0+} f(x) = k$, $k < -1$. Using (a) we find $\lim_{x\to 0+} f^{-1}(x) = 1/k$ and $\lim_{x\to\infty} f^{-1}(x) = k$. However, this implies that the domain of $f(x)$ for negative x is $(k, 1/k)$ which contradicts the fact that f must be defined for all nonzero real values. A similar proof shows that $\lim_{x\to 0+} f(x) = 0$ whenever f is monotonic decreasing in $(0, 1)$.

(e) If $f(x)$ has properties (a) to (d) and $f^{-1}(x) = 1/f(x)$ on $(0, \infty)$, then it is necessary that $f(x)$ be defined for negative x as in (e). Furthermore, $f^{-1}(x)$ must also be defined in $(-\infty, 0)$ by reflecting $f(x)$ on $(0, \infty)$ in the line $y = x$. Using property (a) we see that under these reflections the property $f^{-1}(x) = 1/f(x)$ is preserved for negative x.

Also solved by P. R. Chernoff, Michael Goldberg, Jerome Harrison, G. A. Heuer, H. E. Lahmann (Germany), and Allan Wachs. Several contributors cited some of the characterizing properties and/or gave the example noted above.

Let p be a prime, congruent to 1 (mod 4). Show that $\frac{1}{4}(p-1)$ and -4 are quartic residues (mod p), and that the fourth roots of $\frac{1}{4}(p-1)$ consist of two pairs of consecutive integers.

5549. *Proposed by Steve Ligh, University of Houston*

Let G be an additively written torsion free abelian group. H is any subgroup of G. If the automorphism γ of G/H that takes x onto $-x$ can be lifted to an automorphism α of G that is the identity on H, then G/H splits.

SOLUTIONS OF ADVANCED PROBLEMS

Points of Continuity

5436 [1966, 1019]. *Proposed by Seymour Metz, Computer Associates, Arlington, Va.*

Does there exist a real function on the real line whose points of continuity form a dense set of measure zero?

Solution by E. S. Langford, Naval Postgraduate School, Monterey, Calif. Yes. It is known that if X is any G_δ set, then there exists a function whose set of points of continuity is precisely X. (B. R. Gelbaum and J. M. H. Olmsted, *Counterexamples in Analysis*, Ex. 2.23, p. 30). However, a dense G_δ set of measure zero can be constructed via Cantor sets. (Ibid., Ex. 8.20, p. 99.)

Also solved by D. T. Adams, Duane Bailey, J. P. Celenza, Edgar Cohen, Jr., Carlos Contour-Carrère (Argentina), Leonard Gillman, Michael Goldberg, Robert Goldstein (England), W. L. Griffith, D. A. Hejhal, Ellen Hertz, G. A. Heuer, C. M. Joiner, Jr. & S. J. Pierce, M. D. Mavinkurve (India), P. R. Meyer, J. C. Morgan, Jr., Jürg Rätz (Switzerland), Charles Riley, G. F. Schumm, Al Somayajulu, G. W. Soules, Charles Widger, Albert Wilansky, Dieter Wolke (Germany), and the proposer.

Contour-Carrère proves the result of the problem for R^n, and proves that the collection of points of continuity may contain any prescribed countable set.

Goldstein, using the procedure in the solution above, proves the result: Let m be any nonnegative number. Then there is a real valued function $f(x)$ of the real variable x, whose set of continuity A is a dense set of measure m. Further, any such set A is of the second category.

Although the Editors realize that readers of the MONTHLY wait anxiously to see the solutions of problems, it is not the normal practice to offer a solution in the same issue which proposes the problem. When this situation does occur it merely serves as evidence of the independence of the individual editors in trying to bring out interesting material. We acknowledge, while reeling from the blows, the information from our readers that the solution for this problem was printed just twenty pages earlier in the article by D. B. Goodner, *On points of continuity*, p. 1000.

5547. *Proposed by Anders Bager, Hjørring, Denmark*

Let $\rho(n)$ (resp. $\nu(n)$) be the number of prime divisors of the positive integer n counted with (resp. without) multiplicity. Prove that $\sum_{d|n}(-1)^{\rho(d)}2^{\nu(n/d)}=1$ for all n.

Points of Continuity

5436 [1966, 1019]. *Proposed by Seymour Metz, Computer Associates, Arlington, Va.*

Does there exist a real function on the real line whose points of continuity form a dense set of measure zero?

Solution by E. S. Langford, Naval Postgraduate School, Monterey, Calif. Yes. It is known that if X is any G_δ set, then there exists a function whose set of points of continuity is precisely X. (B. R. Gelbaum and J. M. H. Olmsted, *Counterexamples in Analysis*, Ex. 2.23, p. 30). However, a dense G_δ set of measure zero can be constructed via Cantor sets. (Ibid., Ex. 8.20, p. 99.)

Also solved by D. T. Adams, Duane Bailey, J. P. Celenza, Edgar Cohen, Jr., Carlos Contour-Carrère (Argentina), Leonard Gillman, Michael Goldberg, Robert Goldstein (England), W. L. Griffith, D. A. Hejhal, Ellen Hertz, G. A. Heuer, C. M. Joiner, Jr. & S. J. Pierce, M. D. Mavinkurve (India), P. R. Meyer, J. C. Morgan, Jr., Jürg Rätz (Switzerland), Charles Riley, G. F. Schumm, Al Somayajulu, G. W. Soules, Charles Widger, Albert Wilansky, Dieter Wolke (Germany), and the proposer.

Contour-Carrère proves the result of the problem for R^n, and proves that the collection of points of continuity may contain any prescribed countable set.

Goldstein, using the procedure in the solution above, proves the result: Let m be any nonnegative number. Then there is a real valued function $f(x)$ of the real variable x, whose set of continuity A is a dense set of measure m. Further, any such set A is of the second category.

Although the Editors realize that readers of the MONTHLY wait anxiously to see the solutions of problems, it is not the normal practice to offer a solution in the same issue which proposes the problem. When this situation does occur it merely serves as evidence of the independence of the individual editors in trying to bring out interesting material. We acknowledge, while reeling from the blows, the information from our readers that the solution for this problem was printed just twenty pages earlier in the article by D. B. Goodner, *On points of continuity*, p. 1000.

Also solved by J. P. Celenza, Robert Goldstein (England), D. A. Hejhal, Albert Wilansky, and the proposer.

Several contributors point out that the result is contained implicitly in Kelley, *General Topology*; see p. 208.

See also the paper by Yu-Lee Lee and C. J. Mozzochi, *Topological spaces with large uniformities*, contributed to the American Mathematical Society, Abstract 66T-269 in the Notices.

Infinitely Differentiable Functions

5442 [1966, 1124]. *Proposed by J. T. Renfrow, California Institute of Technology*

Let $f(x)$ be an infinitely differentiable real-valued function defined on an open interval (a, b). If $f(x)$ vanishes infinitely often on a closed bounded subinterval $[c, d]$, $c \neq d$, and $\sup_{x\in(a,b)}|f^{(n)}(x)| = O(n!)$ as $n\to\infty$, then $f(x)$ vanishes identically on an open subinterval of (a, b).

I. *Solution by W. G. Dotson, Jr., North Carolina State University.* By the Bolzano-Weierstrass theorem, the set of zeros of f has a limit point p in $[c, d]$. Suppose k is a nonnegative integer such that the set of zeros of $f^{(k)}$ has p as a limit point. Then, since $f^{(k)}$ is continuous for all x [because $f^{(k+1)}$ exists for all x], $f^{(k)}(p) = 0$. By Rolle's theorem, $f^{(k+1)}$ must have at least one zero between two zeros of $f^{(k)}$; and so p is a limit point of the set of zeros of $f^{(k+1)}$. It follows that $f^{(k)}(p) = 0$ for all nonnegative integers k. Taylor's formula (with Lagrange's form of the remainder) yields

$$f(x) = \sum_{k=0}^{n-1} \{f^{(k)}(p)/k!\}(x - p)^k + \{f^{(n)}(\xi)/n!\}(x - p)^n,$$

x in (a, b), ξ between p and x. There exist $M>0$, $N>0$ such that if $n>N$ then $|f^{(n)}(t)/n!| \leqq M$ for all $t\in(a, b)$; and so for all $x\in(a, b)$ and all $n>N$ we have $|f(x) \leqq M\cdot|x-p|^n$. Thus, if $|x-p|<1$ then $f(x)=0$; and so f vanishes identically on the open subinterval $(\max\{a, p-1\}, \min\{b, p+1\})$.

II. *Solution by R. P. Boas, Northwestern University.* Under the hypothesis $\sup_{x\in(a,b)}|f^{(n)}(x)| = O(n!)$, direct estimation of the remainder in Taylor's series shows that $f(x)$ is the restriction to (a, b) of a function that is analytic on $(a-1, b+1)$. Hence if $f(x)$ vanishes infinitely often on (a, b) (not necessarily on a closed subinterval), it vanishes identically on (a, b). The hypothesis can be weakened to

$$\limsup_{n\to\infty} |f^{(n)}(x)/n!|^{1/n} \leqq 1$$

for each x, i.e. the radius of convergence of the Taylor series about each point in (a, b) is at least 1. (See Boas, Bull. Amer. Math. Soc., 41 (1935), 233–236, or Salzmann and Zeller, Math. Z., 62 (1955), 354–367).

Also solved by D. A. Hejhal, M. D. Mavinkurve (India), Amram Meir, Břetislav Novák, (Czechoslovakia), Stanton Philipp, Charles Riley, C. H. Sampson, Chang Sung-sheng (Taiwan, China), R. J. Weinacht, and the proposer.

The Intersection of Compact Sets in a T_1 Space

5444 [1966, 1124]. *Proposed by T. S. Frank, Le Moyne College, and W. A. Lopez, University of Wisconsin*

It is well known that the intersection of compact sets in a Hausdorff space is again compact. Prove or disprove the corresponding statement for T_1 spaces.

Solution by N. J. Kuenzi, Iowa City, Iowa. In a T_1 space the intersection of compact sets need not be compact. Let $[0, 1]$ be the unit interval and $1'$ a point not in $[0, 1]$. Let $I' = [0, 1] \cup \{1'\}$. Extend the ordering of $[0, 1]$ to a partial ordering of I' by defining $a < 1'$ for each $a \in [0, 1)$ and observe that 1 and $1'$ are not related by this ordering. Extend the usual topology of $[0, 1]$ to I' by defining basic neighborhoods of $1'$ to be sets of the form $(a, 1']$ for $a \in [0, 1)$. This space is easily seen to be T_1 (and not T_2), $[0, 1]$ and $[0, 1']$ are compact sets, but $[0, 1] \cap [0, 1'] = [0, 1)$ is not compact. Clearly I' is not Hausdorff.

Also solved by R. A. Alo, Stephen Baron, John Beidler, Andreas Blass, Sam Cox, Jr., S. W. Dharmadhikari, D. Ž. Djoković (Yugoslavia), Jerry Fischer, S. P. Franklin, R. C. Freiwald, C. F. A Number-theoretic Identity

5446 [1966, 1125]. *Proposed by R. Sivaramakrishnan, Government Engineering College, Trichur, India*

Let $\lambda(n)$ denote the number of distinct prime divisors of n and let $\Omega(n)$ be the total number of prime divisors of n. Prove that

$$\sum_{d|n} (-1)^{\Omega(d)} \phi(d) \sigma(n/d) = \sum_{k^2|n} k^2 \cdot 2^{\lambda(n/k^2)},$$

where $\phi(n)$ is the Euler function and $\sigma(n)$ is the sum of the divisors of n.

I. *Solution by Al Somayajulu, State University of New York, Buffalo.* Since both the left and right sides of the proposed identity are multiplicative functions we need only consider $n = p^\alpha$, p a prime, α a positive integer. If α is even

$$\sum_{d|p^\alpha} (-1)^{\Omega(d)} \phi(d) \sigma(n/d) = (1 + p + \cdots + p^\alpha) - (p-1)(1 + p + \cdots + p^{\alpha-1})$$

The Intersection of Compact Sets in a T_1 Space

5444 [1966, 1124]. *Proposed by T. S. Frank, Le Moyne College, and W. A. Lopez, University of Wisconsin*

It is well known that the intersection of compact sets in a Hausdorff space is again compact. Prove or disprove the corresponding statement for T_1 spaces.

Solution by N. J. Kuenzi, Iowa City, Iowa. In a T_1 space the intersection of compact sets need not be compact. Let $[0, 1]$ be the unit interval and $1'$ a point not in $[0, 1]$. Let $I' = [0, 1] \cup \{1'\}$. Extend the ordering of $[0, 1]$ to a partial ordering of I' by defining $a < 1'$ for each $a \in [0, 1)$ and observe that 1 and $1'$ are not related by this ordering. Extend the usual topology of $[0, 1]$ to I' by defining basic neighborhoods of $1'$ to be sets of the form $(a, 1']$ for $a \in [0, 1)$. This space is easily seen to be T_1 (and not T_2), $[0, 1]$ and $[0, 1']$ are compact sets, but $[0, 1] \cap [0, 1'] = [0, 1)$ is not compact. Clearly I' is not Hausdorff.

A Number-theoretic Identity

5446 [1966, 1125]. *Proposed by R. Sivaramakrishnan, Government Engineering College, Trichur, India*

Let $\lambda(n)$ denote the number of distinct prime divisors of n and let $\Omega(n)$ be the total number of prime divisors of n. Prove that

$$\sum_{d|n} (-1)^{\Omega(d)} \phi(d) \sigma(n/d) = \sum_{k^2|n} k^2 \cdot 2^{\lambda(n/k^2)},$$

where $\phi(n)$ is the Euler function and $\sigma(n)$ is the sum of the divisors of n.

I. *Solution by Al Somayajulu, State University of New York, Buffalo.* Since both the left and right sides of the proposed identity are multiplicative functions we need only consider $n = p^\alpha$, p a prime, α a positive integer. If α is even

$$\sum_{d|p^\alpha} (-1)^{\Omega(d)} \phi(d) \sigma(n/d) = (1 + p + \cdots + p^\alpha) - (p-1)(1 + p + \cdots + p^{\alpha-1})$$

whose coefficients are generated by multiplicative functions:

$$G_p(x, f) = \sum_0^\infty f(p^k)x^k$$

where p is a prime. The set $\{G_p(x, f)\}$ as p ranges over the primes determines f; furthermore $G_p(x, f * g) = G_p(x, f)G_p(x, g)$.

Let μ represent the Möbius function, $n_\alpha(k) = k^\alpha$. We have

$$G_p(x, (-1)^\Omega f) = G_p(-x, f);$$

$$G_p(x, \phi) = G_p(x, \mu * n_1) = G_p(x, \mu)G_p(x, n_1) = \frac{1-x}{1-px};$$

$$G_p(x, (-1)^\Omega \phi) = \frac{1+x}{1+px};$$

$$G_p(x, \sigma) = G_p(x, n_0)G_p(x, n_1) = \frac{1}{1-x}\,\frac{1}{1-px};$$

$$G_p(x, \text{left side}) = \frac{1}{1-p^2x^2}\,\frac{1+x}{1-x}.$$

However, $G_p(x, 2^\lambda) = (1+x)/(1-x)$ and $f(k)$ [$=0$ or k according as k is nonsquare or square] clearly satisfies $G_p(x, f) = 1/[1-(px)^2]$. This completes the proof.

Note that this method was used by Richard Stanley in the solution of 5293 [1966, 553]. Also, in 5290 [1966, 548], the first part is verified by showing

$$G_p(x, t) = \left(\frac{1}{1-x}\right)^2 = \frac{1+x}{1-x}\,\frac{1}{1-x^2} = G_p(x, 2^\lambda)G_p(x, f),$$

where $f(n) = 0$ or $\sqrt{n}$ according as n is nonsquare or square.

Also solved by J. Galambos (Ghana), Ray Glenn, M. G. Greening (Australia), Torleiv Kløve (Norway), S. D. Lawn, Břetislav Novák (Czechoslovakia), Simeon Reich (Israel), Dieter Wolke (Germany), and the proposer.

Property of a One Line Reflection

5447 [1966, 1125]. *Proposed by H. A. Smith, Institute for Defense Analysis*

Let K be a compact subset of the plane having a nonvacuous interior. Let A be a linear transformation on the plane which maps K onto itself. Show that if A does not preserve orientation, then A^2 is the identity.

I. *Solution by Alan Berger, Student, Rutgers—The State University.* Denote $\{Ax \mid x \in K\}$ by $A(K)$, where A is the matrix of the given linear transformation relative to $\binom{1}{0}$ and $\binom{0}{1}$. Since A is real and $|A| < 0$, the eigenvalues λ_1 and λ_2 of A are real and of opposite sign, say $\lambda_1 < 0 < \lambda_2$, and there exists a real nonsingular matrix P such that $PAP^{-1} = J$ where

$$J = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}.$$

Now J^n maps $P(K)$ onto $P(K)$, where n is a positive integer, because $(PAP^{-1})^n = PA^nP^{-1}$ and $PA^nP^{-1}[P(K)] = PA^n(K) = P(K)$. Also $P(K)$ is bounded. Now if $|\lambda_1|$ or $|\lambda_2| > 1$, we obtain a contradiction to $P(K)$ being bounded by taking n sufficiently large, noting K, and thus $P(K)$, contains a basis of $R \times R$. If both $|\lambda_1|$ and $|\lambda_2|$ are less than 1, we look at

$$PA^{-1}P^{-1} = J^{-1} = \begin{bmatrix} 1/\lambda_1 & 0 \\ 0 & 1/\lambda_2 \end{bmatrix}$$

and obtain the same contradiction, for $PA^{-n}P^{-1}$ also maps $P(K)$ onto $P(K)$. Thus

$$J = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix},$$

so $PA^2P^{-1} = J^2 = I$ and $A^2 = I$.

II. *Solution by D. Ž. Djoković, University of Belgrade, Yugoslavia.* From $AK = K$ we get $m(K) = m(AK) = \pm \det A\, m(K)$ where m is the measure. Since K has interior points we have $m(K) > 0$, so that $|\det A| = 1$. Noting that A does not preserve the orientation we get $\det A = -1$. The eigenvalues λ_1, λ_2 of A are real and different, and $\lambda_1\lambda_2 = -1$. We take $\lambda_1 < 0$, $\lambda_2 > 0$. If $\lambda_2 \neq 1$ then either λ_1 or λ_2 has absolute value greater than 1 and the set $K = AK = A^2K = A^3K = \cdots$ cannot be compact. Hence $\lambda_1 = -1$, $\lambda_2 = 1$, which implies that A is a reflection and $A^2 = I$.

III. *Solution by H. Guggenheimer, University of Minnesota.* Since A is linear, $A(K) = K$ implies that A also is an automorphism of the convex hull of K. Hence, by Brouwer's fixed point theorem, A has a fixed point O. By corollary 3.1, p. 297, of Harry Levy, *Projective and Related Geometries*, A is the product of three affine line reflections. Since the lines are concurrent at O, the product can be reduced to one line reflection.

Also solved by E. R. Gentile (Argentina), L. F. Meyers, Charles Riley, and Peter Scherk.

Berger, Guggenheimer and Riley observe that the theorem is true if K is assumed merely to be bounded and have three noncollinear points.

The Trace of the Matrix A, $A^2 = I$

5448 [1966, 1125]. *Proposed by H. A. Smith, Institute for Defense Analysis*

Let A be an $n \times n$ matrix, $A^2 = I$, the identity, and $A \neq \pm I$. Show

$$(1)\ \mathrm{Tr}(A) \equiv n \pmod 2, \qquad (2)\ |\mathrm{Tr}(A)| \leqq n - 2,$$

where $\mathrm{Tr}(A)$ is the trace of A.

Solution by J. E. Vinson, The Boeing Company. Let λ be an eigenvalue of A with eigenvector u. We have $u = Iu = A^2u = A\lambda u = \lambda^2 u$ so that $\lambda = \pm 1$. Suppose exactly m of the n eigenvalues, λ_i $(i = 1, 2, \cdots, n)$, of A are -1. Then

$$|\operatorname{Tr}(A)| = \left|\sum_{i=1}^{n} \lambda_i\right| = |(n-m) - m| = |n - 2m|,$$

which gives (1). Since $A \neq \pm I$, the λ_i are not all of the same sign, i.e. $1 \leqq m \leqq n-1$. It follows that $|\operatorname{Tr}(A)| = |n-2m| \leqq n-2$.

Also solved by Alan Berger, Martin Billik & Eldon Hansen, W. J. Blundon, J. P. Celenza, Richard Citron, W. M. Conner, D. E. Crabtree, C. G. Cullen, D. Ž. Djoković (Yugoslavia), W. G. Vinson, and Jože Vrečko (Yugoslavia).

Uniform Continuity on a Product Space

5449 [1966, 1125]. *Proposed by G. R. Sell, University of Minnesota*

Let $f: K \times R \to R$ be a bounded, continuous function, where R denotes the real numbers and K is a compact set in R. It can be easily shown that if f is uniformly continuous, then f satisfies the following condition:

(U): For every $\epsilon > 0$ there is a $\delta > 0$ such that

$$|f(x, t) - f(x, \tau + t)| \leqq \epsilon, \qquad ((x, t) \in K \times R),$$

whenever $|\tau| \leqq \delta$. Is the converse true? That is, does condition (U) imply that f is uniformly continuous?

Solution by J. R. Isbell, Case-Western Reserve University. No. For instance, let $K = [0, 1]$, let f by 1 above $xt = 1$, let f be 0 on the axes, and take f linear on vertical segments below the hyperbola. We have $f \equiv xt$ if $xt \leqq 1$, and $|f(x, t) - f(x, t+\tau)| \leqq |\tau|$. Finally $f(1/t, t) - f(0, t) = 1$ and f is not uniformly continuous on $K \times R$.

Condition (U) is equiuniform continuity of the functions f_x, where $f_x(t) = f(x, t)$. The general condition for uniform continuity on a product space is this and equiuniform continuity of the similarly defined f^t (III. 21 of *Uniform Spaces*, Amer. Math. Soc. Math. Surveys, no. 12, Providence, 1964). Compactness of K makes uniform continuity of the f_x and equiuniform continuity of the f^t suffice (*ibid.*, III. 24). Neither suffices alone, because of t^2 and the function above.

Also solved by W. M. Causey, D. A. Hejhal, Jan Hejeman (Czechoslovakia), G. A. Heuer, H. E. Lahmann (Germany), M. D. Mavinkurve (India), Amram Meir, Tassos Nakassis (Greece), Břetislav Novák (Czechoslovakia), Charles Riley, Peter Scherk, F. E. Siwiec, and J. B. Wilker.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto, 5, Canada. Correspondence about reviews is welcomed.

Algebra. By Saunders MacLane (University of Chicago) and Garrett Birkhoff (Harvard University). Macmillan, New York, 1967. xix+598 pp. $11.95.

It is natural to compare this book with the authors' *A Survey of Modern Algebra* since it is directed to the same audience. Most of the topics covered in the earlier book appear in some form in the present book; there is one notable exception: Galois Theory is omitted. The following chapters are primarily concerned with topics not included in *Survey:* VI Modules, XV Categories and Adjoint Functors, XVI Multilinear Algebra. Chapter I Sets, Functions, and Universal Elements has no real counterpart in the earlier book.

Despite the large intersection of topics covered in *Survey* and in *Algebra*, the new book is not just an updating of the old. The treatment of many topics and the general tone differ greatly from that of *Survey*. The notation and terminology are "categorical," as are many proofs. Universal properties and duality are introduced in the first chapter and play an essential role throughout most of the book. Many concepts are defined in terms of, or are related to, universal mapping properties; and these properties are used when the concepts are applied.

The linear algebra is distinctly module oriented, in marked contrast to *Survey*. For example, the rational and Jordan canonical forms of a matrix are deduced from the decomposition theorem for modules of finite type over a principal ideal domain.

The level of abstraction is much greater than that of *Survey*, and in the reviewer's opinion students will find it more difficult. But a course from this book should provide the talented and well-motivated student an excellent introduction to the study of algebra.

A. C. MEWBORN, University of North Carolina at Chapel Hill

Introduction to Contemporary Mathematics. By Sze-Tsen Hu. Holden-Day, San Francisco, 1966. viii+202 pp. $7.95.

Awareness of the existence of the infinitesimal calculus is not a prerequisite for reading and understanding this book. However, some mathematical maturity is required for completion of these tasks. Moreover, this requirement is accentuated by the numerous typographical and other errors which appear in almost all parts of the book.

For example, the first entry in the TABLE OF CONTENTS (Page vii) is "Special Symbols and Abbreviations . . . ix." Unfortunately, the review copy contained no page numbered ix, and such a list of symbols and abbreviations is sorely needed. The five chapters are titled Sets and Functions, Number Systems, Algebraic Structures, Geometries, and Elementary Topology, respectively. There is faithful observance of this list and its suggested coverage. On page 20 appears the definition: "Any two functions f and g are said to be *composable* [to form $h=g\circ f$] iff the range of f is equal to the domain of g; . . ." Later, on the same page, appears the example: ". . . let f, g: $R\to R$ denote the functions defined by $f(x)=2x+3$, $g(x)=x^2$ for every $x\in R$. Then the compositions $h=g\circ f$ and $k=f\circ g$ are both defined; · · · ."

After reading this book, one may have the impression that Mr. Hu's "exciting success" in using the manuscript as a text "in a very heterogeneous class of about forty students" constitutes a bright compliment to his effectiveness as a teacher.

WADE ELLIS, University of Michigan

A New Look at Geometry. By Irving Adler, with diagrams by Ruth Adler. John Day, New York, 1966. 414 pp. $7.95.

The aim of this book is to present the reader with a broad view of geometry. It is directed at the layman, or the high school teacher, or perhaps the bright high school student. The author proceeds to his task with a generous sprinkling of historical, philosophical, and scientific allusions. (How one wishes for a Society of Zeno Followers which would exist only to refute Zeno's refuters!) Much pre-Euclidean, Euclidean, and non-Euclidean geometry is presented. Along the way, analytic and vector geometry are developed, and there is a neat, group-theoretic chapter on the algebraic-geometric properties of isometric involutions of the plane. Although no calculus background is expected, discussions of differential geometry and of topology are attempted in separate chapters. Synthetic projective geometry is extensively treated, even to the extent of constructing, in nine unmotivated pages, the underlying field of scalars for an abstract projective plane.

The result is a strange brew. So much undigested, new material is introduced that the reader for whom this book was apparently intended will inevitably be overwhelmed and confused. Included are groups and fields, the infinite series for the hyperbolic and ordinary sine and cosine functions, infinite cardinals, differential and integral calculus, and the axioms for a topological space. In all cases, the motivation and the uses of these topics are quite limited, and frustration would seem to be the inevitable consequence.

In brief, this is an interesting attempt to present geometry in depth. It fails, however, because it does not succeed in being both elementary and comprehensive.

MELVIN HAUSNER, New York University

Lectures on the Foundations of Geometry. By A. V. Pogorelov (Kharkov State University). Translated from the second Russian edition by Leo F. Boron with the collaboration of Ward D. Bouwsma. Noordhoff, Groningen, Netherlands, 1966. 137 pp. $6.90.

After a brief historical sketch (Chapter I), an axiomatization of three-dimensional euclidean geometry is presented in Chapter II, based on five groups of axioms (incidence, order, motion, continuity, and parallelism). In contrast with the five axiom groups of Hilbert, the order axioms are in terms of an order relation for pointpairs, Hilbert's congruence axioms are replaced by seven axioms for motion, and the fourth group contains only one axiom of continuity (Dedekind). The author is able to reach important theorems (e.g., Pythagoras) with rapidity and ease. The axioms themselves are studied in Chapter III. Their relative consistency follows from their cartesian realization, which is established in all detail, and the completeness of the axiom system is proved by showing that every model is isomorphic with the cartesian realization. Independence of the continuity and the parallel axioms is established. On the other hand, three of the seven axioms of motion are derived as theorems (and hence those axioms may be deleted from the system). Hyperbolic geometry (Chapter IV) is dealt with in a fresh way by deriving the planar linear element in absolute geometry (i.e., without making any assumptions concerning parallels). The axioms for hyperbolic geometry are shown to be complete. The concluding Chapter V presents a foundation for projective geometry, with order axioms (in terms of a three-point relation) that permit a rigorous basis for the theory of vectors. Relative consistency and completeness of the axiom system are established.

This small book manages to develop quite rigorously a large amount of material. It is very clearly written, the figures are well-drawn, and no typographical errors were noted. The book is especially well adapted for Summer Institute courses on the foundations of geometry; it is suitable reading for all interested in increasing their general mathematical culture. We interpret as humor the author's warning (p. 30) that a group of axioms is not a group in the mathematical sense!

L. M. BLUMENTHAL, University of Missouri

Linear Algebra. By Serge Lang. Addison-Wesley, Reading, Mass., 1966. x+294 pp. $8.95.

This text was used by each reviewer in his undergraduate class in linear algebra. Its most notable feature is the neatness and elegance of the presentation. An effort is made to prove each theorem as efficiently as possible; computational proofs are avoided in favor of conceptual proofs. This feature is perhaps more appreciated by the instructor than by the students, who did not seem to be able to learn more from this text than from the one it replaced.

The first eleven chapters of the book treat the material usually included in an undergraduate course in linear algebra and can just about be covered in a single semester with an average class. Lang considers only vector spaces over subfields of the complex numbers; the great majority of the proofs carry over to vector spaces over general fields.

The reviewers found Chapter VI on determinants to be unsatisfactory. Lang utilizes Artin's elegant approach and develops determinants from their properties. The student needs an explanation and outline of this approach. Lang attempts to summarize everything in one main theorem (Theorem 1) at the start of the chapter. The proof of this main theorem is actually not completed until Section 6 of the chapter; however, this is not made clear to the student.

Proofs of the theorems concerning the rank of a matrix are exceptionally well done. These theorems are treated as corollaries of theorems on the rank of a linear transformation and the dimension of the orthogonal complement of a subspace under a nondegenerate scalar product.

The book contains a nice combination of routine, computational problems and exercises requiring more ingenuity. While the book is not free from errors, there are not an unusual number for a first edition. The reviewers consider this to be an above average linear algebra text, which, however, could be improved.

R. D. KOPPERMAN AND J. B. FRALEIGH, University of Rhode Island.

La Régularité Moyenne dans la Théorie Métrique. By W. J. Trjitzinsky. Mémor. Sc. Math., fasc. 157, Gauthier-Villars, Paris, 1965. 88 pp. NF26.

The origin of this research monograph lies in the generalization by A. Denjoy of the classical Vitali covering theorem. The hypothesis of Vitali's theorem involves the topology of the space while the conclusion is purely measure-theoretic. Denjoy approached the problem by removing the topology; as a simple example, instead of a sequence of sets with diameter approaching zero, there is substituted a sequence with measure approaching zero. This direction was pursued in a series of papers and further generalized by Trjitzinsky [Théorie métrique . . . , Mémor. Sc. math., fasc. 143, 1960]. The volume under review continues this generalization.

The first third of the monograph involves proofs of covering theorems under less restrictive hypotheses than previously assumed in the literature and constructions of examples to show the new assumptions are indeed weaker. Then these theorems are applied to obtain generalizations of classical results in the Lebesgue theory. Thus under suitable assumptions, the density (relative to a family of covering sets) of a measurable covered set is almost everywhere equal to the characteristic function. Further results deal with differentiation of set functions, the Lebesgue decomposition theorem, and analogues of the Vitali-Carathéodory and Lusin theorems. A final section deals with cellular divisions of an abstract space; these divisions lead to a metric for the space but the present volume does not exploit the idea any further.

Since many proofs are only indicated as modifications of proofs that appear in the author's previous monograph, it is recommended that both volumes be read together. As may be inferred, this book is not meant for the casual reader, but for the specialist it represents an interesting approach to a problem of intrinsic interest.

GERALD FREILICH, The City College, New York

Linear Algebra. By Serge Lang. Addison-Wesley, Reading, Mass., 1966. x+294 pp. $8.95.

This text was used by each reviewer in his undergraduate class in linear algebra. Its most notable feature is the neatness and elegance of the presentation. An effort is made to prove each theorem as efficiently as possible; computational proofs are avoided in favor of conceptual proofs. This feature is perhaps more appreciated by the instructor than by the students, who did not seem to be able to learn more from this text than from the one it replaced.

The first eleven chapters of the book treat the material usually included in an undergraduate course in linear algebra and can just about be covered in a single semester with an average class. Lang considers only vector spaces over subfields of the complex numbers; the great majority of the proofs carry over to vector spaces over general fields.

The reviewers found Chapter VI on determinants to be unsatisfactory. Lang utilizes Artin's elegant approach and develops determinants from their properties. The student needs an explanation and outline of this approach. Lang attempts to summarize everything in one main theorem (Theorem 1) at the start of the chapter. The proof of this main theorem is actually not completed until Section 6 of the chapter; however, this is not made clear to the student.

Proofs of the theorems concerning the rank of a matrix are exceptionally well done. These theorems are treated as corollaries of theorems on the rank of a linear transformation and the dimension of the orthogonal complement of a subspace under a nondegenerate scalar product.

The book contains a nice combination of routine, computational problems and exercises requiring more ingenuity. While the book is not free from errors, there are not an unusual number for a first edition. The reviewers consider this to be an above average linear algebra text, which, however, could be improved.

TELEGRAPHIC REVIEWS

The following abbreviations indicate suggested uses: T (textbook), S (supplementary student reading), P (professional reading for the teacher), TT (teacher training), L (library purchase), 15 (junior level)—18 (second graduate year).

Séminaire Bourbaki. Volume 1965/1966. Exposés 295–312. Benjamin, New York, 1966. 311 pp. The thirteenth (and first current) volume of the series covering the papers presented at the Paris seminars presided over by the redoubtable N. Bourbaki. L.

Romanian-English Dictionary and Grammar for the Mathematical Sciences. By S. H. Gould (American Mathematical Society) and P. E. Obreanu (Queen's University, Kingston). American Mathematical Society, 1967. v+51 pp. $7.10 ($5.33 to members of AMS). Designed for English-speaking mathematicians, it includes a basic Romanian grammar. P, L.

Dictionary of Physics and Mathematics Abbreviations, Signs and Symbols. Edited by David D. Polon. Odyssey, New York, 1965. xvi+333 pp. $20.00. Includes much related material such as abbreviations for learned societies. L.

Analysis

Introduction to the Operational Calculus. By Lothar Berg (University of Halle). North-Holland, Amsterdam (Wiley, New York, in U.S.A. and Canada), 1967. x+294 pp. $12.00. A translation of the second German edition with the insertion of exercises by the author. The modern Mikusinski approach is linked with the traditions of Heaviside and Laplace transforms. T (15–16), S, P.

Constructive Real Analysis. By Allen A. Goldstein (University of Washington). Harper, New York, 1967. xii+178 pp. $9.25. "My object in this book is to introduce students of mathematics, science, and technology to the methods of applied functional analysis and applied convexity. To demonstrate and illustrate these techniques I have applied them to the related problems of finding zeros and extremals of functions and operators, with and without side conditions. For students of mathematics the book can perhaps be regarded as an initiation to 'hard analysis,' while for students of science, an initiation to 'soft analysis'." Prerequisites are courses in modern advanced calculus and linear algebra. T(16–17), S, P.

Differential Operators of Mathematical Physics. By Günter Hellwig (Technische Hochschule Aachen). Translated from the German by Birgitta Hellwig. Addison-Wesley, Reading, Mass., 1967. viii+296 pp. $12.50. An introduction to differential operators for students with advanced calculus and ordinary differential equations. The main topics are Hilbert space, linear operators, spectral theory of completely continuous operators, and the Weyl-Stone Eigenvalue Problem. There are very few problems. T(16), S, P.

Elements of Real Analysis. By Sze-Tsen Hu (University of California, Los Angeles). Holden-Day, San Francisco, 1967. xii+365 pp. $10.95. With this book the author keeps up his amazing output of one advanced level book per year since 1959. This one covers most of the material recommended by CUPM: sets, functions and relations, the real line, topological spaces, metric spaces, topological linear spaces, measures and integrals (including the Lebesgue and Daniell approach), differentiation. T (16–17).

Multiple Integrals. By Walter Ledermann. Dover, New York, 1966. vi+106 pp. $1.00 (paper). One of a series of inexpensive paperbacks "primarily intended for readers who study mathematics as a tool" and aiming "to cover the topics which are usually included in courses of mathematics for scientists, engineers and statisticians . . . " It includes the traditional material on line, double, surface, and volume integrals. Existence theorems are stated but not proved. Other related volumes in the series, all priced the same, are *Differential Calculus* by P. J. Hilton, *Integral Calculus* by W. Ledermann, *Partial Derivatives* by P. J. Hilton, *Elementary Differential Equations and Operators* by G. E. H. Reuter, *Sequences and Series* by J. A. Green, *Differential Geometry* by K. L. Wardle, *Fourier Series* by I. N. Sneddon, and several others. A selection might be used to cover a course with greater convenience and lower cost than by using the usual massive tomes. T (13–14), S.

Theory of Functions of a Complex Variable. Volume III. By A. I. Markushevich (Moscow State University). Revised English edition translated and edited by R. A. Silverman. Prentice-Hall, Englewood Cliffs, N. J., 1967. xi+360 pp. $12.95. The last volume of this very substantial course in complex variables, which includes many examples, problems, illustrations, and bibliographic references. Topics here covered are conformal mapping, approximation theory, periodic and elliptic functions, Riemann surfaces, analytic continuation. T (17), S, T.

Commutation Properties of Hilbert Space Operators and Related Topics. By C. R. Putnam (Purdue University). Springer-Verlag, New York, 1967. xi+167 pp. $7.00. Bounded operators, spectral theory, semi-normal operators, quantum mechanics, wave operators, unitary equivalence, Laurent and Toeplitz operators, singular integral operators and Jacobi matrices, substantial bibliography and indexes. P.

Modern Nonlinear Equations. By Thomas L. Saaty (Conference Board of the Mathematical Sciences). McGraw-Hill, New York, 1967. xv+473 pp. $15.50. Primarily a reference book, covering operator, functional, difference, delay-differential, integral, integrodifferential, and stochastic differential equations. There are two chapters on basic concepts and techniques, bibliographies at the end of each chapter, but no problems. Together with *Nonlinear Mathematics* by Saaty and Joseph Bram (McGraw-Hill, 1964, reviewed in this MONTHLY 73, 323), which covered algebraic and differential equations, this volume completes the coverage of "all the major types of classical equations except partial differential equations." T (17–18), S, P, L.

An Introduction to Analysis. By Wilson M. Zaring (University of Illinois). Macmillan New York, 1967. xi+364 pp. $9.95. This text "was designed specifically for the prospective teacher of calculus," and has been used for several years in Academic Year Institutes for high school teachers at the University of Illinois. It consists of Part I on logic and set theory followed by Part II, an introduction to analysis. T (13–15), TT.

Applications

The Theory of Splines and Their Applications. By J. H. Ahlberg (United Aircraft Research Laboratories), E. N. Nilson (Pratt and Whitney Aircraft Company), and J. L. Walsh (University of Maryland). Academic Press, New York, 1967. xi+284 pp. $13.50. A treatise on a field that dates from 1946. "The mathematical spline is the result of replacing the draftsman's spline by its elastica and then approximating the latter by a piecewise cubic. . . . " P.

Mathematical Reasoning in Economics and Management Science, Twelve Topics. By John C. G. Boot (SUNY at Buffalo). Prentice-Hall, Englewood Cliffs, N. J., 1967. xii+178

pp. $7.95. The twelve topics are characteristic roots and vectors, difference equations, assorted problems in probability theory, Markov chains, decision criteria and utility curves, game theory, strategies, dynamic programming, sensitivity analysis, elementary inventory models, growth models, and Leontief models. In each the mathematical theory and applications are given. Coverage is not intended to be deep, but there are references for further study. S, P, L.

Decision Rules for Inventory Management. By Robert Goodell Brown (Arthur D. Little, Inc.). Holt, Rinehart, and Winston, New York, 1967. x+398 pp. $9.95. A mathematical treatise in the form of technical memoranda written by Roger ("a new type of business student . . . with an engineering degree and a strong interest in mathematics . . . ") for his superiors in the Warmdot Company. S, P.

Foundations of Mechanics. A mathematical exposition of classical mechanics with an introduction to the qualitative theory of dynamic systems and applications to the three-body problem. By Ralph Abraham (Princeton University) with assistance of Jerrold E. Marsden (Princeton University). Benjamin, New York, 1967. ix+296 pp. $14.75. This unusually attractive and interesting looking book starts with a "Museum" of twenty-nine portraits, including several contemporaries who are very far from being relegated to any museum, continues with a brief historical introduction to the main body consisting of revised notes on a series of lectures "aimed at recent mathematical results in mechanics, especially the work of Kolmogorov, Arnold and Moser and its applications to Laplace's question of the stability of the solar system," and concludes with appendices by Marsden, Al Kelly, and Kolmogorov. There are exercises and several bibliographies. The pre-requisites are "the mathematical background of a physics graduate student." Anyone who imagines that mathematics has cut itself off from the traditional interaction with physics and astronomy should look at this treatment of classical mechanics in the language of modern differential geometry. T (16–17), S, P, L.

Prague Studies in Mathematical Linguistics, Vol. I. Edited by Lubomir Dolezel, Petr Sgall, and Josef Vachek. University of Alabama Press, 1966. 240 pp. $8.50. This is the first of a series published under the auspices of the Czechoslovak Academy of Sciences. It contains nineteen papers on statistical linguistics, algebraic linguistics, and machine translation, fourteen in English and five in Russian. P, L.

Gyroscopic Theory. By Sir G. Greenhill. Chelsea, Bronx, New York, 1966. viii+275 pp. $9.50. Reprint of the original report (London, 1914) "intended to serve as a collection in one place of the various methods of the theoretical explanation of the motion of a spinning body." P, L.

Advanced Engineering Mathematics. By Erwin Kreyszig (Ohio State University). 2nd ed. Wiley, New York, 1967. xvii+898 pp. $11.95. The usual topics including probability and statistics, special functions, complex variables, partial differential equations and the Laplace transformation. T (15).

Scattering Theory. By Peter D. Lax (New York University) and Ralph S. Phillips (Stanford University). Academic Press, New York, 1967. xii+276 pp. $12.00. "Scattering theory compares the asymptotic behavior of an evolving system as t tends to $-\infty$ with its asymptotic behavior as t tends to $+\infty$." This monograph presents a new approach to scattering theory for hyperbolic differential equations. Tools used are spectral theory, harmonic analysis, semi-groups, and various aspects of partial differential equations. T (17–18), S, P.

Blanch Anniversary Volume. A series of papers presented on the occasion of her retirement by the friends of Gertrude Blanch. Edited by Bertram Mond. (Aerospace Research Laboratories, Wright Patterson AFB, Ohio) United States Air Force, 1967. In an anniversary volume of this sort one has a right to expect some biographical information, a bibliography, possibly a portrait. Except for less than a page of rather vague praise for Dr. Blanch, this volume consists of a miscellaneous collection of papers whose relationship to the person being honored is not indicated. P.

Finite Deformation of an Elastic Solid. By Francis D. Murnaghan. Dover, New York, 1967. 140 pp. $1.85 (paper). An unaltered reprint of the original 1951 publication, dedicated by the author "to the Glory of God, Honor of Ireland, and solidarity of the Americas." T (16), S, P.

An Introduction to Magnetohydrodynamics. By P. H. Roberts (School of Mathematics, University of Newcastle upon Tyne). American Elsevier, New York, 1967. x+264 pp. $11.00. Devoted to the mathematics of the subject but with some attention to problems of application and significance. P.

Introduction to the Theory of Operational Research. By B. van der Veen. PhilipsTechnical Library and Springer-Verlag, New York, 1967. vii+204 pp. $9.20. A non-technical introduction to "the mathematical and operational aspects" of queueing problems, stocks, industrial dynamics, multi-stage decisions, dynamic programming, linear programming, game theory, network planning, operations research and decisions. S (15), P.

Education

An Introduction to Fibonacci Discovery. By Brother U. Alfred (St. Mary's College, California). The Fibonacci Association, San Jose State College, San Jose, Calif., 1965. 56 pp. $1.50 (paper). A reprint of the pamphlet in response to its wide use as a device for stimulating student activity in mathematics. It deals briefly with many topics, including mathematical induction, shift formulas, the Fibonacci and Lucas sequences, division properties, generalized Fibonacci sequences, Pascal's triangle, the golden section, matrices, and continued fractions. It may be ordered from Brother U. Alfred, St. Mary's College, California 94575, at bulk prices of $1.25 each for from 4–9 copies, $1.00 each from 10–24 copies, and $0.75 each for 25 or more copies.

Number Systems: An Elementary Approach. By J. Richard Byrne (Portland State College). McGraw-Hill, New York, 1967. xiii+291 pp. $6.95. Primarily for future elementary teachers, this book ends by defining a real number "as an infinite sequence of rational numbers which can be represented by an infinite decimal," states that the set of real numbers is complete, but omits the proof "because it is beyond the scope of this book." TT.

Teaching Modern Mathematics in the Elementary School. By Howard F. Fehr (Teacher's College, Columbia University) and Jo McKeeby Phillips (University of Illinois Curriculum Laboratory). Addison-Wesley, Reading, Mass., 1967. xvi+448 pp. $7.95. Beginning and ending with chapters on general pedagogical questions, this book deals with arithmetic and geometry in the spirit of the "new math." Included are chapters on teaching ratio, proportion, and per cent, problem solving and enrichment topics. TT.

Mathematics for Elementary School Teachers. By Helen L. Garstens and Stanley B. Jackson (University of Maryland). Macmillan, New York, 1967. xii+500 pp. $9.95.

Mathematical reasoning, whole numbers, mathematical structure, sets and geometry, congruence in geometry, the integers, the rationals, linear measurement and coordinates, angle, area, volume, coordinates and similarity, plus three appendices on the pyramid volume formula, spherical geometry, geographical maps, and "a geometrical fantasy" (a universe on a spherical surface). TT, P.

Exploring University Mathematics 1, Lectures Given at Bedford College, London. By P. Chadwick, J. H. E. Cohn, H. G. Eggleston, J. R. Ellis, G. T. Kneebone, M. Levison, S. J. Taylor. Edited by N. J. Hardiman. Pergamon, New York, 1967. x+120 pp. $2.95 (paper), $4.50 (cloth). Though addressed to secondary school students, these lectures contain interesting observations on such matters as the history of foundations, relativity, digital computers, and the isoperimetric problem. S, P, L.

International Study of Achievement in Mathematics, a comparison of twelve countries. Edited by Torsten Husen. Wiley, New York, 1967. Two volumes, 303+368 pp. $19.95. This is a report on phase one of the International Project for the Evaluation of Educational Achievement. It has already received considerable publicity (The U.S. ranks tenth in mathematics achievements of 13-year olds.) and deserves more thoughtful analysis and discussion than can be given in the book review section. See *Science* 30 June 1967 for a critical review. P, L.

Report of the International Clearinghouse on Science and Mathematics Curricular Developments, 1967. Edited by J. David Lockard. A joint project of the American Association for the Advancement of Science and the Science Teaching Center, University of Maryland, College Park, Md., 1967. xxxvii+413 pp. Single copies free to individuals on request to the editor, International Clearinghouse on Science and Mathematics Curriculum Developments, Science Teaching Center, University of Maryland, College Park, Md. 20740. This describes in detail a large number of projects and has indexes by geographical location, name of director, level (including college and miscellaneous) and subject matter. P, L.

Research in Mathematics Education. National Council of Teachers of Mathematics, Washington, D. C., 1967. vi+125 pp., (paper) $2.00. This publication, which might be the precursor of a journal for research in mathematics education, contains eleven papers, three of which survey the field and argue for its importance, and eight that report on recent research. The lead article by Patrick Suppes is an eloquent plea for basic research in mathematics education in order "to understand how students learn mathematics, and to use this understanding to outline more effective ways of organizing the curriculum." P, L.

In-Service Education in Elementary School Mathematics. The National Council of Teachers of Mathematics, Washington, D.C., 1967. iv+55 pp. $.90 (paper). This informative booklet for all those interested in in-service programs for teachers includes a bibliography and a list of addresses in each state from which information can be obtained. TT, L.

Theory of Arithmetic. By John A. Peterson (University of Montana) and Joseph Hashisaki (Western Washington State College). 2nd ed. Wiley, New York, 1967. xiv+337 pp. $7.50. This revision of a book first published in 1963 is motivated by the fact that future teachers are coming to mathematics courses with a more adequate background. It begins with a brief history of numeration and ends with the real numbers and topics from geometry. TT.

mation on numerical methods and statistics. A basic knowledge of computer programming is assumed. P.

Multivariate Analysis. Proceedings of an International Symposium held in Dayton, Ohio, June 14–19, 1965. Edited by Paruchuri R. Krishnaiah (Wright-Patterson Air Force Base). Academic Press, New York, 1966. xix+592 pp. $19.50. Contributions by thirty-nine authors covering both methodology and applications in a very wide range. P, L.

Combinatorial Methods in the Theory of Stochastic Processes. By Lajos Takacs (Case Institute of Technology). Wiley, New York, 1967. xi+262 pp. $12.75. This treatise contains largely original work of the author. It aims to show how a generalization of the "classical ballot theorem" can be used to solve a very wide class of problems. P.

A Graduate Course in Probability. By Howard G. Tucker (University of California, Riverside). Academic Press, New York, 1967. xiii+273 pp. $12.00. A high level compact text designed for a graduate course presuming no previous study of probability but substantial background in real analysis or measure theory. The material is tailored to a one-year course ending with conditional expectation, Martingale theory, stochastic processes and Brownian motion. T (17–18), S, P, L.

Acknowledgement. The following have generously helped in evaluating books: T. M. COVER, T. EVANS, R. C. N. HOURSTON, W. LOUD, S. M. ROBINSON, D. ROSEN, P. SCHERK, R. SINGLETON, D. H. SKYPEK, E. F. WILDE.

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor E. F. Myers, University of Pittsburgh, represented the Association at the inauguration of President A. A. Blum of Point Park College on June 18, 1967.

Memphis State University: Mr. M. L. Heen has been promoted to Assistant Professor; Associate Professors E. B. McBride and D. T. Walker have been promoted to Professors.

SUNY at Buffalo: Associate Professor K. D. Magill, Jr., has been promoted to Professor and appointed Chairman of the Mathematics Department for 1967–68; Assistant Professor S. R. Cavior has been promoted to Associate Professor; Dr. R. G. Bauer, University of Massachusetts, and Dr. Margaret G. Piech, Cornell University, have been appointed Lecturers; Mr. C. K. Chui, University of California, San Diego, and Dr. Vladimir Drobot, University of Illinois, have been appointed Assistant Professors; Dr. V. L. N. Sarma, Hindu University, has been appointed Visiting Associate Professor; Professor Dov Tamari will be on leave at the Institute for Advanced Study at Princeton.

Associate Professor F. T. Birtel, Tulane University, has been promoted to Professor.

Dr. H. P. Edmundson, University of Maryland, has been appointed Professor of Computer Science and Mathematics at the University of California, Los Angeles.

mation on numerical methods and statistics. A basic knowledge of computer programming is assumed. P.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

MARCH MEETING OF THE METROPOLITAN NEW YORK SECTION

The annual meeting of the Metropolitan New York Section of the MAA was held at Long Island University, Zeckendorf Campus, on March 18, 1967. Dr. Meyer Jordan, Vice-Chairman of the section for Senior Colleges, presided. There were approximately 120 persons in attendance.

At the business meeting, the following officers were elected: Chairman, Professor Meyer Jordan, Brooklyn College; Vice-Chairman for Senior Colleges, Professor Joseph Houle, Pace College; Vice-Chairman for Junior and Community Colleges, Professor Norman Schaumberger, Bronx Community College; Vice-Chairman for High Schools, Dr. Ira Ewen, Springfield Gardens High School; Secretary, Professor Theresa J. Barz, St. John's University; Treasurer, Dr. Aaron Shapiro, Midwood High School.

Also at the business meeting, Dr. Abraham Schwartz reported on the meetings of the Board of Governors, Dr. C. T. Salkind and Dr. N. Schaumberger reported on the activities of the Contest Committee and the Speakers' Bureau, respectively, while Dr. A. Shapiro presented the treasurer's report.

The following papers were presented:

1. *Probability methods in various branches of mathematics*, by Mark Kac, The Rockefeller University (by invitation).

2. *One hundred years to square a logarithm*, by Harold Shapiro, New York University.

3. *Calculus for secondary school teachers*, by Lester Gavurin, Brooklyn College.

4. *Some reactions to CUPM proposals*, by J. E. Houle, Pace College.

5. *An experimental program in freshman calculus*, by Howard Levi, Hunter College.

6. *The effectiveness of a programmed text for mathematics fundamentals—an experiment at Pace College*, by Maurice Nadler, Pace College.

7. *Freshman experimental course in modern mathematics*, by Maurice Richter, Staten Island Community College.

8. *Mathematics for prospective elementary school teachers*, by Margaret Woodbridge, Brooklyn College.

THERESA J. BARZ, *Secretary*

JUNE MEETING OF THE NORTHEASTERN SECTION

The spring meeting of the Northeastern Section of the Mathematical Association of America was held at Mount Allison University, Sackville, New Brunswick on June 24, 1967. Thirty-five people attended the meeting including twenty members of the Association. Professor Robin Robinson, Chairman of the Section, presided at both the morning and afternoon sessions.

The following program was presented:

1. *Random packing of spheres and applications*, by E. M. Tory, Mt. Allison University.

2. *What is a calculation?* by Joachim Lambek, McGill University.

3. *The Sylvester Theorem and some of its applications*, by Michael Edelstein, Dalhousie University.

4. *Knotting, nylon, and nucleic acids*, by E. M. Brown, Dartmouth College.

G. W. BEST, *Secretary-Treasurer*

JUNE MEETING OF THE PACIFIC NORTHWEST SECTION

The annual meeting of the Pacific Northwest Section of the MAA was held at the University of Montana, Missoula, Montana on June 16 and 17, 1967. There were 67 members of the Association in attendance. Professor W. R. Ballard, Chairman of the Section, presided over the Friday sessions which were held jointly with the Northwest Section of SIAM. Mr. John Knutson presided over the Junior and Community College Sessions.

At the business meeting the following officers were elected: Chairman, C. T. Long, Washington State University; Vice-Chairman, Ronald Harrop, Simon Fraser University; Second Vice-Chairman, Theodore White, Everett Junior College; Secretary-Treasurer, E. A. Maier, University of Oregon. The position of Second-Vice-Chairman is a new office in the Section. The duties of the office include serving as representative of the two-year colleges to the Executive Committee, arranging for the program of the Junior and Community College Session at the annual Section meeting and presiding over these sessions.

The program of the joint sessions with SIAM was as follows:

1. *Bounds on the eigenvalues of nonhomogeneous strings*, by D. C. Barnes, Washington State University (by invitation).

2. *Report of the ad hoc subcommittee of CUPM on the qualifications of college teachers of mathematics*, by L. J. Paige, University of California at Los Angeles.

3. *Structure theorems for Banach Algebras*, by Bertram Yood, University of Oregon (by invitation).

4. *The application of biharmonic eigenfunctions to a plate problem*, J. W. Weber, Washington State University (by invitation).

The program of the Junior and Community College session was as follows:

1. *Report on the ad hoc committee of the NCTM on two-year college mathematics*, by Theodore White, Everett Junior College.

2. *Practical approach to trigonometry*, by David Fine, Everett Junior College (by invitation).

3. *How to put a number scale on the Euclidean line?* by S. A. Jennings, University of Victoria (by invitation).

4. *Notes in the margin of a calculus book*, by H. E. Reinhardt, University of Montana (by invitation).

5. *The use of audio-visual materials in the teaching of mathematics*, by Norman Barton, Vancouver City College (by invitation).

6. *Circular functions from a square viewpoint*, by James Van Dyke, Portland Community College (by invitation).

E. A. MAIER, *Secretary-Treasurer*

CALENDAR OF FUTURE MEETINGS

Fifty-first Annual Meeting, San Francisco Hilton, California, January 25–27, 1968.

Forty-ninth Summer Meeting, University of Wisconsin, Madison, Wisconsin, August 26–28, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, Indiana University of Pennsylvania, Indiana, April 27, 1968.

FLORIDA, Miami-Dade Junior College, South Campus, Miami, March 22–23, 1968.

ILLINOIS, Southern Illinois University, Edwardsville Campus, May 10–11, 1968.

INDIANA

IOWA, Wartburg College, Waverly, April 19, 1968.

KANSAS, Marymount College, Salina, March 23, 1968.

KENTUCKY, University of Kentucky, Lexington, April 20, 1968.

LOUISIANA-MISSISSIPPI, Broadwater Beach Hotel, Biloxi, Mississippi, February 16–17, 1968.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA

METROPOLITAN NEW YORK, Staten Island Community College, Staten Island, March 16, 1968.

MICHIGAN

MINNESOTA

MISSOURI, Lindenwood College, St. Charles, April 27, 1968.

NEBRASKA, Nebraska Center for Continuing Education, Lincoln, April 26–27, 1968.

NEW JERSEY, Rider College, Trenton, May 4, 1968.

NORTHEASTERN

NORTHERN CALIFORNIA, San Francisco Hilton, January 27, 1968.

OHIO

OKLAHOMA-ARKANSAS, Federal Aviation Agency, Oklahoma City, March 29–30, 1968.

PACIFIC NORTHWEST, Reed College, Portland, Oregon, June 14–15, 1968.

PHILADELPHIA

ROCKY MOUNTAIN, University of Denver, Colorado, May 10–11, 1968.

SOUTHEASTERN, East Carolina College, Greenville, North Carolina, March 29–30, 1968.

SOUTHERN CALIFORNIA, Loyola University of Los Angeles, March 9, 1968.

SOUTHWESTERN, New Mexico State University, University Park, Spring 1968.

TEXAS, Texas A and M University, College Station, April 19–20, 1968.

UPPER NEW YORK STATE, Hamilton College, Clinton, May 11, 1968.

WISCONSIN, Wisconsin State University, La Crosse, May 4, 1968.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE: Dallas, Texas, December 26–31, 1968.

AMERICAN MATHEMATICAL SOCIETY, San Francisco Hilton, January 23–26, 1968.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, University of California, Los Angeles, June 17–20, 1968.

ASSOCIATION FOR COMPUTING MACHINERY, Chicago, Illinois, August 20–22, 1968.

ASSOCIATION FOR SYMBOLIC LOGIC, University of California, Los Angeles, March 22, 1968.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, St. Louis, November 28–30, 1968.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Hall, Philadelphia, Pennsylvania, April 17–20, 1968.

48 films from MAA

Calculus. Arithmetic. Mathematics Today. 48 films for both teacher training and classroom use. All produced by the Mathematics Association of America or its committees. These films are available on a purchase, lease-to-buy, or subscription rental basis through Modern Learning Aids. For additional information, complete this coupon and mail it to the address below.

Please send complete information about the following:

☐ **Calculus Films.** 14 animated 16mm-sound films produced by the Calculus Film Project of the MAA Committee on Educational Media. For first-year college level and high school advanced placement courses.

☐ **Arithmetic Films.** 7 animated 16mm-sound films produced by MAA. For teacher training and elementary classes.

☐ **Mathematics Today.** 28 16mm-sound films from the Individual Lectures Project of the Committee on Educational Media. For college level and advanced mathematics courses.

McGraw-Hill Invites You To Play

MATHEMATICS QUIZOMETRY

Instructions: Score one point for each time you answer yes.

Questions		No. of Points
1 As a student I have read a McGraw-Hill textbook authored by one of these mathematicians:	R. P. Agnew, Eric Temple Bell, Ruel Churchill, Lester Ford, Ross Middlemiss, Ivan Sokolnikoff, or J. V. Uspensky	☐
2 As a teacher I have used in a class a McGraw-Hill textbook authored by one of these people:	Lars Ahlfors, Carl Allendoerfer, Creighton Buck, Lyman Kells, Cletus Oakley, Walter Rudin, George Simmons, or C. R. Wylie	☐
3 Or I have recommended to a student one of these McGraw-Hill self-help supplements:	M-H Programmed Modern Math Series, Schaum's Outlines, Burington's HANDBOOK OF MATH TABLES AND FORMULAS, or Korn's MANUAL OF MATHEMATICS, plus many more	☐
4 Or I am currently using one of these authored McGraw-Hill textbooks:	a)—Any of the above, or b)—E. Heineman, G. Fuller, V. Robison, J. R. Byrne, Howard Taylor, T. E. Wade, or Sherman Stein, plus dozens of others	☐
5 As a professional mathematician, I am ordering a copy of the following McGraw-Hill book authored by:	Edward Spanier, Glen Bredon, Seymour Goldberg, Joseph Wolf, Dale Husemoller, Errett Bishop, Irving Segal, Ray Kunze, Hartley Rogers, or T. L. Saaty.	☐
	TOTAL	☐

Many of you will score ten or more points. If you have fewer don't be discouraged because the year 1968 is going to be an outstanding one for you to add impressively to your score with the following authors scheduled for publication:

Garrett Birkhoff, Thomas Bartee, George Feeman, Neil Grabois, F. Bedford, Rene Dennemeyer, Richard Laatsch, Donald Monk, Grace Bush, John Young, Alston Householder, David Ledbetter, John Moore, Daniel Mostow, Joseph Sampson, Paul Ritger, Nicholas Rose, L. R. Snyder, George Wallace, John Dettman, Sam Selby, Leonard Sweet, and others.

...And to examine these exceptional texts

AN INTRODUCTION TO MODERN MATHEMATICS.
By NATHAN J. FINE, Pennsylvania State University.

Integrated by continuing themes such as logic and set theory, this text permits course planners to omit proofs, sections, or even whole chapters to suit individual needs. The book is designed to introduce freshmen majors in social science and the liberal arts to theoretical mathematics. It is also of value to advanced high school students and prospective teachers. Only two or three years of high school mathematics are required. This text provides terminal students with clear insights to the nature of mathematics and some major achievements in the field. It presents a stimulating combination of exposition, proofs, and exercises, followed by index and bibliography.

509 pp., $8.50

TRIGONOMETRY REVIEW MANUAL, First Edition.
By WILLIAM HAUCK, University of Wisconsin.
Smith and Moore Mathematics Series

This programmed review is confined to the essentials necessary for the use of trigonometry in other areas of mathematics and in science. The manual consists of eight linear programs, each of which is preceded by an introductory statement and a pretest to point out areas calling for particular review. A self-test keyed to individual frames follows each section. The book is designed for college and junior college precalculus courses, mathematics surveys, and remedial mathematics courses. **Winter**

PREPARATION FOR BASIC STATISTICS.
By VIRGINIA A. CLARK, University of California, Los Angeles, and MICHAEL E. TARTER, University of Michigan.

This text is programmed to provide a background in mathematics for an introductory statistics course. It is particularly helpful for students weak in mathematics taking an applied statistics course as given in psychology, sociology, business administration, education, public health, and other departments. The book is written, not only so that students can use it on their own, but also so the instructor can assign whatever material he feels his students need, depending on their preparation. Pretest questions are provided at the beginning of each chapter. **Off Press**

BASIC MATHEMATICAL SKILLS: A Text-Workbook.
By LOYCE C. GOSSAGE, Mt. San Antonio Junior College.

This textbook/workbook in remedial arithmetic emphasizes translating basic computations and practical word problems into simple and soluble solutions for college students. Explanations include numerous detailed examples, number lines, and other illustrations. Fundamental equations with whole numbers are thoroughly developed before the introduction of short-cut methods, word problems, common fractions, and decimal fractions. The book presents a wealth of practice material in the exercises and quizzes; and each exercise presents something new. Problems are presented in the order of their difficulty, with review problems appearing in the ending exercises and quizzes. **320 pp., $3.95**

New Texts from Macmillan

REAL ANALYSIS, Second Edition

By H. L. Royden, Stanford University

The aspects of modern mathematics that have their roots in the classical theory of functions of a real variable are covered thoroughly in the second edition of this widely adopted text. Topics receiving special attention include: measure and integration, point-set topology and the theory of normed linear spaces. In this edition the author has added more problems, simplified proofs where necessary, and included a completely new chapter on measure and topology.

1968, approx. 320 pages, prob. $10.95

TENSOR ANALYSIS ON MANIFOLDS

By Richard L. Bishop and Samuel I. Goldberg,
both of the University of Illinois

Tensor Analysis on Manifolds presents tensor fields in a setting which clarifies the nature of their domains of definition, namely, manifolds, and, separately examines in detail their algebraic aspects, namely, the topic of multilinear algebra. These are then combined and specialized to give a logical development of other usual topics such as vector analysis, integration theory (differential forms), and hamiltonian as well as riemannian structures. Emphasis is given to structure rather than manipulative skills.

1968, approx. 320 pages, prob. $11.95

CONTEMPORARY COLLEGE ALGEBRA AND TRIGONOMETRY

By William A. Gager, University of Florida

Written in modern mathematical language, this book is designed to encourage, motivate and guide students toward a clear understanding of the fundamentals of algebra and trigonometry. After the basic ideas of set theory and the real number system have been developed, the dominant feature is the concept of function and relation. The book concludes with a modern introduction to probability. A detailed, illustrated solutions manual is available.

1968, approx. 416 pages, $7.95

MODERN CALCULUS WITH ANALYTIC GEOMETRY, Volumes I and II

By A. W. Goodman, University of South Florida

Mathematical rigor, clarity of expression and lively imaginative language make this an excellent text for the calculus sequence. All important theorems are proved without embellishment but with ample discussion to make each step clear. Difficult material is starred. Problems are carefully graded, and answers to all problems are given. Volume I covers single-variable calculus and Volume II covers multivariable calculus, linear algebra, determinants and differential equations.

Volume I: 1967, 808 pages, $10.95
Volume II: 1968, approx. 512 pages, prob. $9.95

CONTEMPORARY ARITHMETIC

By Thomas C. Crooks and Harry L. Hancock,
both of Contra Costa College

This text presents basic computational methods, utilizing over 3000 intensive drill problems in exercise sets, chapter tests, summary tests and review tests. The exposition begins with an explanation of natural numbers (and addition, subtraction, multiplication, and division) and proceeds to common and decimal fractions, percent, denominate numbers, involutions, and introductory plane and solid geometry. A second color and over 150 illustrations are used to emphasize important concepts. The answers to selected problems are included in the text. A Solutions Manual is available, gratis.

1968, approx. 304 pages, prob. $5.95

Write to the Faculty Service Desk for examination copies.

Outstanding texts

AN INTRODUCTION TO MATRICES, VECTORS AND LINEAR PROGRAMMING

HUGH C. CAMPBELL, *Virginia Polytechnic Institute.* This text, designed to teach matrix algebra to students with a limited mathematical background, is particularly useful in terminal courses. *244 pp., illus., $6.50*

ELEMENTARY CONCEPTS OF MODERN MATHEMATICS

FLORA DINKINES, *University of Illinois, Chicago.* Hardbound, *457 pp., illus., $6.50,* or in three paperbacks: ELEMENTARY THEORY OF SETS, *237 pp., illus., $2.65;* INTRODUCTION TO MATHEMATICAL LOGIC, *122 pp., illus., $1.65;* and ABSTRACT MATHEMATICAL SYSTEMS, *97 pp., illus., $1.45*

CALCULUS WITH ANALYTIC GEOMETRY

EDWIN J. PURCELL, *University of Arizona.* Rigorous enough to challenge the best student, this text features an early introduction of set theory and a thorough coverage of vectors in two- and three-dimensional spaces. *843 pp., illus., $11.00*

Appleton-Century-Crofts

MATHEMATICAL ASSOCIATION OF AMERICA
SUNY at Buffalo (University of Buffalo)
Buffalo, New York 14214

Forthcoming Spring

FIRST-YEAR CALCULUS

Einar Hille, *Yale University*

For students who are concurrently studying science and/or engineering, the integral as well as the derivative is presented early in this introductory text. The essential features of integration and differentiation can easily be covered within the first nine weeks of class. Emphasized is the coherence meaningful to the student at this level. The text also offers an abundance of motivational material throughout —examples, problems worked out, exercises—enough for every kind of classroom situation. *in press*

MODERN PROGRAMMING: FORTRAN IV

Henry Mullish, *New York University*

Explains by example and description the basic concepts involved in submitting problems written in the Fortan IV language. Particularly suited to the formulation of scientific problems, although equally suitable to other areas, the text should present no difficulties since it resembles the grammar and syntax of the English language. *in press*

ORDINARY DIFFERENTIAL EQUATIONS

Garrett Birkhoff, *Harvard University*
Gian-Carlo Rota, *The Rockefeller Institute*

A revision of this standard text correlates elementary theory of differential equations and advanced method techniques. Illustrating general principles by the study of important special functions starting from the differential equations which they satisfy, this text will be of value to pure and applied mathematicans. *in press*

THE COMPUTER PROGRAMMER'S DICTIONARY AND HANDBOOK

Donald D. Spencer, *Apollo Support Department, General Electric Company*

An all-inclusive compilation of material related to the general field of computer science embracing standard, current, informative, and historical entries. This dictionary is comprehensive enough to be a supplementary handbook for the professional and apprentice programmer as well. *in press*

PERTURBATION METHODS IN APPLIED MATHEMATICS

Julian D. Cole, *California Institute of Technology*

Surveying perturbation methods particularly with reference to differential equations, this text illustrates general features common to various examples. The basic ideas, however, are also applicable to integral equations, integro differential equations, and even difference equations. Written from the point of view of the applied mathematician, the text uses physical reasoning extensively to aid in understanding the problem. The primary mathematical tool employed is asymptotic expansion in terms of a parameter. *in press*

NUMERICAL METHODS FOR TWO-POINT BOUNDARY-VALUE PROBLEMS

Herbert B. Keller, *Firestone Laboratories, California Institute of Technology*

A brief elementary account of numerical methods for solving very general two point boundary value problems. Three techniques are studied in detail: initial value or "shooting" methods, finite difference methods, and integral equation methods. Each method is applied to nonlinear second order problems, and the first two methods are applied to first order systems of nonlinear equations. Over one hundred problems augment and elucidate the text. *in press*

BLAISDELL PUBLISHING COMPANY

A Division of Ginn and Company

275 Wyman Street, Waltham, Massachusetts 02154

It is commonly recognized that inadequate communication exists between the mathematician and the general public. And now something has been done about it:

THE NATURE OF MATHEMATICS

By FREDERICK H. YOUNG, *Oregon State University*

With this new book, the general reader or student can readily and quickly acquire a remarkable understanding of some of the aims, techniques and results of modern mathematics. He will, for example, be led from the intuitive algebra of sets to abstract Boolean algebra, which in turn will lead him, through application, to switching circuits and to logic. This unique development from the concrete to the abstract and back again is particularly successful in providing both understanding and an increased facility in logical manipulation.
A detailed Instructor's Manual is available. *1968. 407 pages. $7.50.*

Other new mathematics books:

PLANE TRIGONOMETRY
Second Edition

By NATHAN O. NILES, *United States Naval Academy, Annapolis.* This excellent text was used by more than 70 colleges and universities in its first edition. In the Second Edition there is an even smoother flow of ideas. The definition of a function in terms of sets, more use of vectors in discussing complex numbers, and a new section on logarithmic and exponential equations have all been added. The biggest change is in the improved problems and new review sets for each chapter. *1968. 282 pages. $5.95.*

INTRODUCTORY ALGEBRA
A College Approach *Second Edition*

By MILTON D. EULENBERG *and* THEODORE S. SUNKO, *both of Wilbur Wright College.* New material on inequalities and the number system have been added to the second edition of this new carefully written textbook. *1968. 317 pages. $6.50.*

COLLEGE GEOMETRY

By LAWRENCE A. RINGENBERG, Dean of the College of Letters and Science, *Eastern Illinois University.* An outstanding text for the modern college geometry course. It is flexible enough to follow either old fashioned or modern high school courses. *1968. 308 pages. $8.95.*

INTRODUCTION TO AUTOMATA

By R. J. NELSON, *Case Western Reserve University.* A unified presentation of Turing machines, programming systems, finite sequential machines, finite and infinite state transition systems, pattern recognizers, push-down automata, and generative grammars, as well as the mathematical theory of finite state and context-free languages. *1967. 400 pages. $12.95.*

MATHEMATICAL LOGIC

By STEPHEN C. KLEENE, *University of Wisconsin.* Beginning with a thorough yet elementary treatment of the propositional and first-order predicate calculi and equality, this book proceeds to some of the newest ideas and more profound results of modern logic. *1967. 398 pages. $10.95.*

MATHEMATICS AND COMPUTING
with FORTRAN Programming

By WILLIAM S. DORN, *International Business Machines; and* HERBERT J. GREENBERG, *University of Denver.* An Annotated Instructor's Manual is now available for this book. *1967. 595 pages. $8.95.*

JOHN WILEY & SONS, Inc. *605 Third Avenue, New York, N.Y. 10016*

new / recent texts for 2ND semester

mathematics for elementary school teachers: a first course

James W. Armstrong. Intended for prospective and in-service elementary school teachers, this class-tested, one-semester text consists of a detailed, unified treatment of the fundamental aspects of number, based upon natural and intuitive definitions. Rigor is maintained at the highest level commensurate with the students' ability and background. Exclusion of less important ideas results in full comprehension of the basic concepts. Teacher's Guide. **Coming February**

finite mathematics

William H. Richardson. FINITE MATHEMATICS is a class-tested, one-semester text covering the following general topics: Mathematical Logic, Set Theory, Counting and the Binomial Theorem, and Probability. After finishing the text, the student will have the necessary tools for further study in such areas as statistics and matrix algebra (including linear programming and game theory) for business and social science studies. There are 284 exercises as well as numerous solved problems throughout the text. Answers to odd-numbered problems are included in the text; others are given in a separate booklet. **Coming January**

ordered topological vector spaces

Anthony L. Peressini. Bringing together information largely available only in scattered research papers, this text is a systematic treatment of the theory of ordered topological vector spaces. It includes motivational material and many examples and applications, and discusses in detail Choquet simplexes, order convergance, continuity and extensive properties of positive linear mappings and functions, ordered topologies, etc. **Just Published**

Major new books from Macmillan

INTRODUCTION TO STATISTICS

By Ronald E. Walpole, Roanoke College

For students majoring in any academic discipline, this text draws its numerous illustrative examples and exercises from many different fields of application. Requiring only high school algebra, the text is modern in approach and includes discussions of decision theory and Bayesian statistics. It is based on the premise that statistics can best be taught by first introducing the fundamental concepts of the theory of probability based on set theory.

1968, approx. 304 pages, prob. $7.95

ARITHMETIC: Concepts and Skills

By Murray Gechtman and James Hardesty, both of Los Angeles Pierce College

This text for remedial arithmetic courses offers clear explanations of basic arithmetic concepts, accompanied by over 2500 effective drill exercises. The system of whole numbers is first presented through the primitive notion of sets. The text then considers integers, rational numbers, and real numbers. Exercises include problems in percentage, ratio, proportion, area, volume, and computation in place value numerical systems with bases other than ten. The text is attractively designed with a second color to emphasize important concepts. Answers to odd-numbered problems are given at the end of the text, and a Solutions Manual, available gratis, provides answers to even-numbered problems.

1968, approx. 272 pages, prob. $5.95

ELEMENTARY LINEAR ALGEBRA

By Marvin Marcus and Henryk Minc, both of the University of California, Santa Barbara

Designed for freshman and sophomore students with a limited mathematical background, this text covers vector spaces, matrices, determinants, characteristic roots, and quadratic functions. Relatively few concepts are introduced and these are discussed at several levels of abstraction.

1968, approx. 256 pages, prob. $7.95

TRIGONOMETRY: An Analytic Approach

By Irving Drooyan and Walter Hadel, both of Los Angeles Pierce College

Concepts and notations as well as a review of the real number system are presented in the first chapter of this thoroughly modern text. A second color is used functionally throughout. Available gratis are a Teacher's Supplement and Solutions Manual. Progress Tests and Answers to Progress Tests are also available.

1967, 308 pages, $5.50

A NONPARAMETRIC INTRODUCTION TO STATISTICS

By Charles H. Kraft and Constance van Eeden, both of The University of Montreal

This book is designed specifically for courses in which a nonparametric approach is employed. Introductory chapters, presupposing only high school algebra, consider concepts of inference prior to probability. An introduction to common designs and their analysis is then presented through brief descriptions of particular tests and their exact and approximate distributions. Extensive statistical tables and numerous examples and exercises with solutions are provided.

1968, approx. 304 pages, prob. $9.95

Write to the Faculty Service Desk for examination copies.

THE MACMILLAN COMPANY 866 Third Avenue, New York, New York 10022

1968

NEW TITLES FOR FALL CLASSES

College and University Mathematics: A Functional Approach

By Donald R. Barr, U.S. Naval Postgraduate School, and Floyd E. Willmore, Wisconsin State University at Oshkosh. An understanding of the foundations of mathematics is developed for the first year college course. Throughout, functions and their applications are stressed. A multi-track feature offers the instructor flexibility in determining the level a which he conducts the course. April, 1968.

Introduction to Algebraic Structure

By Joseph Landin, University of Illinois at Chicago Circle. Praised by reviewers as well written and extremely easy to follow, this text offers two semesters of material for a first course in modern or abstract algebra. It rigorously defines concepts with the aid of illustrative examples. Problems both challenge and instruct the student. April, 1968.

Basic College Algebra, Second Edition

By Julian Mancill and Mario O. Gonzalez, both of the University of Alabama. The central theme of the first edition, mathematical completeness and directness on a reasonable level of rigor, is maintained in this new edition. Essentially this text: 1. develops the real and complex number systems; 2. reviews elementary algebra; and 3. treats the conventional mathematical applications of elementary algebra. April, 1968. Est. 464 pp.

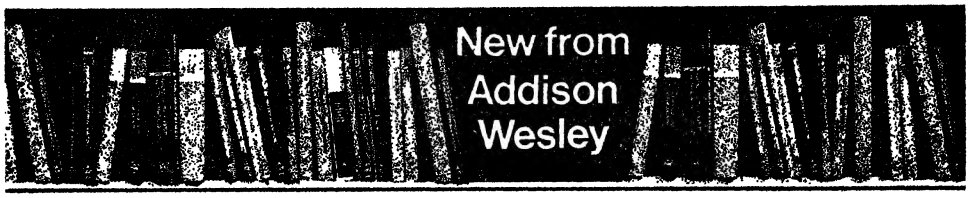
Introduction to Modern Algebra, Second Edition

By Neal H. McCoy, Smith College. Important algebraic systems are introduced slowly and carefully to upper level undergraduate or graduate level students, with special attention to points which might cause difficulty. The text proceeds from rings to integral domains to fields, with numerous illustrations of each concept as it is introduced. March, 1968. Est. 320 pp.

Elementary Algebra, Third Edition

By Donald S. Russell, Ventura College. The third edition continues to instruct college students with no formal background in algebra as well as those who feel the need for review before further mathematical study. The present edition features more application of set theory to algebraic solutions and more extensive development of inequalities as applied to algebraic development. April, 1968.

Linear Algebra: An Introductory Approach, Second Edition



By Charles W. Curtis, University of Oregon. Abstract concepts are presented at the beginning and are followed by a careful treatment of applications to linear equations, matrix theory and analytic geometry, giving a clear impression of the source of the abstract ideas. A new arrangement of topics adapts itself more easily to the one semester or two quarter course. April, 1968.

Calculus with Analytic Geometry

By John A. Tierney, United States Naval Academy. The 1965 Committee (CUPM) report to the Mathematical Association of America states that "mathematical understanding is a matter of degree, and some kinds of informal understanding can be adequate for a long time." Here underlying concepts are presented so as to be understood and appreciated by the average student. Feb. 1968. Est. 650 pp.

A FIRST COURSE IN CALCULUS, Second Edition
A SECOND COURSE IN CALCULUS, Second Edition
A COMPLETE COURSE IN CALCULUS

BY SERGE LANG
Columbia University

Now available in either a single edition or separate volumes, this well-known text retains all of the features of the earlier edition.

The first volume is primarily concerned with the basic notions of derivative and integral, and the basic techniques and applications which accompany them. The second volume covers linear algebra and functions of several variables. Together they are designed for a two-year introductory course.

SPECIAL FEATURES OF THIS EDITION

1. Linear algebra is applied to functions of several variables, viewing the derivative as a linear map.
2. The number of exercises has been doubled.
3. The book ends with a first introduction to normed vector spaces, and the (ε, δ) language of limits in this context—especially good preparation for students going on to an advanced calculus course.

CONTENTS—Volume I

Numbers and Functions. Graphs and Curves. The Derivative. Sine and Cosine. The Mean Value Theorem. Sketching Curves. Inverse Functions. Exponents and Logarithms. Integration. Properties of the Integral. Techniques of Integration. Some Substantial Exercises. Applications of Integration. Taylor's Formula. Series. Complex Numbers.

CONTENTS—Volume II

Vectors. Differentiation of Vectors. Functions of Several Variables. The Chain Rule and the Gradient. Potential Functions and Line Integrals. Higher Derivatives. Maximum and Minimum. Vector Spaces. Linear Equations and Bases. Linear Mappings. Linear Maps and Matrices. Determinants. Applications to Functions of Several Variables. Multiple Integrals. Green's Theorem. Orthogonality and Fourier Series. ϵ and δ.

Volume I: c. 336 pp. 119 illus. Approx. $8.50
Volume II: c. 288 pp. 111 illus. Approx. $7.95
Complete: In press

SETS, FUNCTIONS, AND PROBABILITY

By JOHN B. JOHNSTON, *General Electric Research and Development Center,* and G. BALEY PRICE and FRED S. VAN VLECK, *University of Kansas.*

This book is intended to provide a foundation in sets, functions, and probability, while giving a large number of applications of these subjects in a wide variety of fields. Illustrations, applications, and exercises are chosen largely from the fields of business and management sciences, the biological sciences, and the social sciences. Many of these have not appeared previously in any elementary textbook. *c. 400 pp. 107 illus. Approx. $8.95*

MODERN ALGEBRA AND TRIGONOMETRY
Second Edition

By ELBRIDGE P. VANCE, *Oberlin College*

The second edition of this widely-used text has as its aim the education of the student in the nature of mathematics as a logical system. It offers a unified treatment of algebra and trigonometry and may be used in either a one- or two-semester course. This edition includes new and detailed material on matrices and a new approach to vectors. The problems have been augmented, and five new sets of review problems have been added.

c. 416 pp. 102 illus. Approx. $8.95

THE SIGN OF EXCELLENCE

Announcing the new FOURTH EDITION by THOMAS

CALCULUS AND ANALYTIC GEOMETRY

CALCULUS AND ANALYTIC GEOMETRY, *Fourth Edition—Complete*

Part I: FUNCTIONS OF ONE VARIABLE AND ANALYTIC GEOMETRY

Part II: LINEAR ALGEBRA, VECTORS AND FUNCTIONS OF SEVERAL VARIABLES

BY GEORGE B. THOMAS, JR.
Massachusetts Institute of Technology

This is the new Fourth Edition of a highly-regarded and well-proven text designed primarily for students of science and engineering.

This edition retains the early introduction to integration, the high degree of motivation, and the clear, thorough explanations which have made the text so popular with students and teachers alike.

Major New Features:

- Chapter 13, *Linear Algebra,* is entirely new. Its location makes it available for use with Chapter 15 in connection with the chain rule.
- Chapter 17, *Vector Analysis,* is also a new chapter. The chief results are Green's theorem, the divergence theorem, and Stokes' theorem.
- In the new chapter on limits (Chapter 2), the author does not stop with the definition, but uses it primarily to prepare for application to the formal techniques of differentiation.

Contents:

THE RATE OF CHANGE OF A FUNCTION
LIMITS
DERIVATIVES OF ALGEBRAIC FUNCTIONS
APPLICATIONS
INTEGRATION
APPLICATIONS OF THE DEFINITE INTEGRAL
TRANSCENDENTAL FUNCTIONS
HYPERBOLIC FUNCTIONS
METHODS OF INTEGRATION
PLANE ANALYTIC GEOMETRY
POLAR COORDINATES
VECTORS AND PARAMETRIC EQUATIONS
LINEAR ALGEBRA: VECTORS IN N-SPACE
VECTOR FUNCTIONS AND THEIR DERIVATIVES
PARTIAL DIFFERENTIATION
MULTIPLE INTEGRALS
VECTOR ANALYSIS
INFINITE SERIES
COMPLEX NUMBERS AND FUNCTIONS
DIFFERENTIAL EQUATIONS
